Time of exposure .....	10 min.
Single stop .....	Extension/35.

The first two items are self-explanatory, the last needs comment. The aperture of the stop is one thirty-fifth of the extension of the camera from stop to sensitive plate, and that stop will admit the exact amount of light required by the conditions under which the stop is used.

**Screen distance, etc.**—The determination of this takes some time to determine for aperture of stop used, and must be done by each worker. Once ascertained, it remains constant, and any operator with the above data given can produce negative after negative of good uniform quality.

I have experimented under other conditions as to lenses, screens, etc., and found the extension to vary from thirty to forty-five times the size of the stop, whether it be owing to colour of glass screen, varying perhaps through the colour of the Canada balsam, or the glass, or the light, or perhaps a combination of these and other factors. I say, therefore, accept the principle and work to your own conditions.

In further repeating the experiment twice, from the same copy we will reduce one and considerably enlarge the other, maintaining the screen distance and time of exposure; those used to copying will say, "Oh, but if you are going to reduce, you must expose less, or, if to enlarge, you must increase your exposure." Well, so I do, but by an alteration of one factor only, i.e., the stop, the others remaining permanent, the amount of light admitted previously having given just the amount of closing up of the dots, to produce the exact result wanted, the easiest way I can see to admit the same amount of light again, i.e., the same amount relatively, though the stop be larger or smaller, is as

Fig. 1.

follows:—Produce a scale E 35 on a strip of cardboard or stiff paper, say 45 inches long and two inches wide, set out from A 35 inches to B, and drop a vertical line from B one inch long to the point C—from A draw a diagonal line through C and the scale is complete. With a penknife cut through the line AC, and the scale can be fixed on the side of the tailboard, A being level

Fig. 2.

with the stop aperture, the camera will extend freely without interfering. At any point on the line AB, that the ground glass may come to rest after focussing one thirty-fifth of the extension is automatically indicated under the arrow-head by the width of a vertical line from the line AB to the line AC, and this gives the size of stop required. With extension towards B for enlargement or movement towards A for reduction the increase or decrease in stop is shown by where we find the arrow-point.\* In practice the scale may be set out along the tailboard, the usual progressive numbers of the iris diaphragm can be dispensed with and other divisions corresponding with the tailboard indications marked on the mount, the iris diaphragm lends itself well to exactness. I attach no great importance to the shape of the stop, believing that many shapes of stop will produce what is wanted if other conditions are right. The Levey stop (Fig. 3) I always regarded as faulty, because when overlapping, as in exposure, the corners did not coincide, the tendency being to produce large joinings of insufficient density. The stop which I first suggested (Fig. 4) is, I believe, superior for joining up dots, as the corners do fall upon each other, and practically give double the light action at these points. I do not see how this can be made in iris form, and otherwise it cannot be so finely adjusted as the circular one, the various sizes progressing in steps, more or

A brief discussion followed Mr. Middleton's paper. The following is the report of it which is appended to the official text of the communication:

Mr. A. J. Newton said he was sorry he had not heard the whole of Mr. Middleton's paper, but thought he had heard the principal points. He asked if Mr. Middleton had brought examples of work produced under the conditions laid down. He (Mr. Newton) had found that when one stop only was used with originals of great contrast they generally lost gradation, and to get more perfect results two stops had to be used, or

\* If one find the aperture wanted is one-fortieth, then the vertical line in Fig. 1 should be put 40 inches from A, a vertical line B of 1 inch long dropped to C and the same method followed. If E. 30 is required the vertical line B must be dropped 30 inches from A, B, and so on.

less gradual, according to the number provided. A square stop, if preferred, can be made in iris form, and possibly curves could be calculated for giving an iris stop a modified square of this form (Fig. 5), for those who incline to the stop with strong corners.

There is nothing in this principle of working to scale to prevent those who prefer two stops using them, but I would suggest always maintaining a determined ratio between the exposures, say, one-half the total for each size.

One cannot in a single paper cover all the various ramifications of half-tone work, but I may say a word or two on copies; if the

Fig. 3.

Fig. 4.

Fig. 5.

copies are faulty every possible improvement ought to be made upon them by the artist; that being done, mentally divide them into three classes—good, too heavy, too flat. If a copy be perfect, the use of a single stop is the most practical way of getting the full gradation. How often do we find the more artistic work with "atmosphere" or "feeling" reproduced badly—or not at all. I believe the multiple stop business accounts for much of this; the balance has not been struck, and a copy false in the middle tones results. This is less likely to occur when one stop only is used. If a copy is too hard, is heavy in the shadows and has chalky lights, cut the shadows up by using a stop a size less than indicated on the tailboard; this will also keep the high lights sharp, but, of course, increases the time of exposure. In extreme cases a pre-exposure may be allowable as a time-saver if it must be understood that half-tone exposures are of necessity very long from the fact that shadows which produce, or, rather leave, almost clear glass in ordinary negatives have to be exposed so long that opacity is produced in the dots representing them. A point, that I have never seen alluded to, may be called attention to here, and that is that the fact that when we look at a half-tone illustration the image has been produced by those portions of the negative that have been totally covered with the screen lines, and have never been exposed to light in the camera, or action of the lens at all.

In the case of a flat copy lacking in contrast, the screen distance should still be maintained, but a stop a size larger than indicated should be used, and the exposure should be shortened.

I have indicated the principle of a method which I carried into practice for some years, one which I consider produced creditable work with a reduction of negative waste and fine etching, but happily I am now otherwise engaged. There are other conditions not alluded to that possibly prevent the rule being absolute in all cases, but I think there is latitude sufficient in the manipulation of the negative to cover this, and if my rule is but half a rule, I hope—like half a loaf—it is better than none, and that my remarks may direct more capable thinkers to a very wide subject.

E. C. MIDDLETON.

one stop made in such a way as to be equivalent to two. The principles which Mr. Middleton advocated were well known, and had to be in some cases departed from in favour of double exposures. The methods of finding the size of stop, when one only was used, as suggested by Mr. Middleton, had been published by Mr. Biermann in "Penrose's Annual" for 1907. The lecturer advocated that the originals should be worked up, but in many cases that would not be allowed. In artistic work it was not permitted to touch the originals at all. It was necessary to obtain a perfect negative of the original in the condition in which it was delivered, and the special qualities required in a half-tone negative could not always be produced with one stop. Mr. Newton quite agreed that one stop might be used for

ying normal originals, but he would undertake to say that average operator using two stops would get better results than the totality of his work than would a man using one stop only, for everything. These remarks apply to wet collodion, which Mr. Middleton recommends; the conditions are different in the case of dry plate and collodion emulsion.

Mr. Fogwell said that he could quite endorse what had been said about the use of one stop, and had found in practice that an ideal stop was round in shape, and it was infinitely better in the use of two or more stops for the preservation of true colour values, and to prevent the harsh jumps from one tone to another, which were so often made when multiple stops are employed, but its exclusive use was impossible in a process of use, owing to diversity of copy, and other matters, and the compromise he had effected was a round stop with lacinated edges, practically a multiple pointed star. Mr. Middleton had said that a perfect half-tone negative should have perfect black and white, but Mr. Fogwell differed from him in that, and said there was a fallacy of old process workers, who had all along been endeavouring to obtain this opacity and clear glass result from both collodion emulsion and dry plates, which leave a halo round the dot. This partially prints on the metal plate and is technically known as "scum," and he had found that this scum on the metal plate was a very decided advantage, as it held the half-tones in etching, thereby allowing the highest lights, which had very much less of the scum, to etch faster than the middle tones.

Mr. Middleton said the opposite opinions expressed by his critics as to stops well illustrated the divergency of opinion, and

as his methods had been published in "Penrose's Annual" it would appear as if he had appropriated the ideas. As a matter of fact, the author of the article was in the same town as himself—Birmingham—and had obtained the suggestion, perhaps not directly, but certainly indirectly, from him. As long ago as 1875 he (Mr. Middleton) had published his ideas, though briefly, in the "British Journal." He had no doubt that the inexperienced operator working without a rule to assist him would get passable results by using a number of stops, because he made his error cover a wider area, but if he applied the rule laid down and worked with one stop only he would get less errors and more perfect results. That scum round the dot assisted in the production of the block was quite a mistake; it led to waste in printing, because a longer or shorter exposure produced different results. With a black and white negative a much wider range of exposure in printing produced no variation in the range. If the dot was hard, and the spaces clear, printing became mechanical. He had found the value of his methods by experience. A youth who had had no experience in making half-tone negatives was told to work absolutely to the rule, with the result that a high percentage of negatives were so perfect that they could be printed from automatically. He (Mr. Middleton) had been out of the block-making business for some years, and could not, in consequence, exhibit examples of his work. At the time he was engaged in the business collodion was in exclusive use, and he had not used gelatine plates. He did not think it was possible to produce the same quality of work with dry plates as with wet collodion.

## MICROSCOPIC RESEARCHES ON THE PLATE-GRAIN.

In the BRITISH JOURNAL, February 15, 1907, I published researches from which it can be seen that there are reasons for dividing the definition of plate-grain into at least three divisions. We have in the exposed film:—

(1) Original grains—i.e., grains which have germs round

Fig. 1.

themselves, which germs are the points where development commences. These original grains are not dissolved by development.

(2) Dissolving grains—grains which show no germs, and

which are dissolved either partly or entirely by chemical development.

(3) Developed black grains.

The veiling grains of the unexposed plate behave like original grains, and the unexposed grains behave like dissolving grains

Fig. 2.

in exposed films—i.e., they are only dissolved in chemical developers if they are in the same solution close together with original grains. The researches published here examine the relation of dissolving and original grains under different con-

ditions of development and exposure. In the experiments Figs. 1, 2, and 3, only the time of exposure was changed. All other conditions were the same. The time of exposure of the three films had the ratio of 1 : 100 : 60,000. In Fig. 1,

Fig. 3.

beside the developed grains we see many dissolving grains which are not at all, or only partly, dissolved, and the original grains which are not yet covered by the developed grain. In Fig. 2 all dissolving grains have disappeared. We

Fig. 2 is longer exposed, and Fig. 3 is solarised. As we have already stated, in the three films the concentration of the developing solution, the temperature, and the time of development were equal. From these experiments it results that the solubility of the dissolving grains in chemical developers is governed by the exposure, and the solubility increases at commencement corresponding with the exposure up to a maximum, after which it decreases with the increasing exposure.

The curve of the solubility of the dissolving grains corresponds with the well-known blackening curve; it rises quickly with the increasing exposure, and it decreases slowly. The rising portion is the part of the normal exposure. Its slow decreasing part the solarisation. The curve of solubility of the dissolving grains is probably similar to the curve which indicates the mass of the developed grains formed in every case. In the figures Nos. 4 and 5 the action of developing solutions of different concentration is shown. The exposure and the time of development were unchanged in this case.

Both films are solarised, Fig. 4 is developed in a dilute solution, and Fig. 5 in a ten-times stronger solution of developer. It can be seen that the solubility of the dissolving grains, as well as the size (i.e., the general mass) of the developed grains, corresponds with the concentration of the developing solution. We call "optimum of exposure" an energy of light acting upon the plate, which in development gives a picture like Fig. 2—i.e., which causes the dissolving of all dissolving grains and the maximum of size of the developed grains. From the Figs. 4 and 5 it can be seen that the optimum of exposure is quite different for the different concentrations of developing solutions, and that also the part of the curve which indicates this optimum has quite a different length towards the rising part of the curve, as also towards the decreasing part of the curve. The stronger the developing solution, the weaker the exposures sufficient to reach the

Fig. 4.

Fig. 5.

see only the developed grains and some original grains which are not covered. The developed grains are much larger here than in Fig. 1. In Fig. 3, beside the relatively few developed grains we see many dissolving grains, and some original grains resting upon the developed grains. Fig. 1 is a short exposure,

maximum size of the developed grain, and the later the decreasing of the curve sets in when we increase the exposure. It is well known that it is easy to considerably change the density curve by changing the ratio of the solution of the developer and the other conditions of development. Therefore,

is not correct to say "exposed at optimum": we must take note as to the conditions of development. Figs. 6 and 7 show that the size of the developed grains depends upon the number of grains in the unit volume of

the place of Fig. 6 the quantity of grains in the unit-volume has been greater than in the case of Fig. 7. Probably this phenomenon is caused by the fact that if the grains lie more closely together the germs are immersed in a more concentrated

Fig. 6.

Fig. 7.

fine. The less grains are suspended in the unit volume the smaller is the size of the developed grains, all conditions being the same—viz., exposure and development—remaining the same. The Figs. 6 and 7 are of the same plate, only in

solution of developer than in films poorer in grains. In films rich in grains the quantity of the dissolved dissolving grains lost by the formation of developed grains can be recovered more quickly and more efficiently.

DR. W. SCHEFFER.

#### HINTS ON BIRD PHOTOGRAPHY.

OLIVER G. PIKE, in the "Birdland Booklet," just issued by Messrs. Sanders and Crowhurst, gives the following hints on the difficult branch of photography:—

When stalking a bird, don't walk straight towards it, but walk in a zigzag fashion, stopping every few steps.

When photographing a bird at a nest, always try to be hidden with the camera.

Never keep a bird off its eggs more than two hours. If it does not do so in that time there is something wrong with the photographer's method of hiding.

If it is not possible to hide with the camera, use string, or an electric release for the shutter. When using the former, attach the string to the shutter release with a piece of thin cotton. This will prevent the camera rocking during exposure, for if the string is pulled too hard the cotton breaks.

If a long pneumatic release is not satisfactory, the air wave takes time to pass from the ball to the shutter. The quickest and best method of all is the electric.

Don't try to do impossible things with the "Birdland" camera. When you blame the camera for your non-success. The camera will do more than any other hand camera made; but it is emphatically a camera for photographing birds, animals, and insects, and is not suitable for nests. A half-plate camera with a long swing should be used for the latter.

Don't try to make exposures with a telephoto lens while holding the camera in the hand. A solid support must in such cases be used. Remember that it is always better to obtain a small and sharp image of the bird on the plate than a large and badly focussed one. It is always better to use backed plates when photographing sea

A very rigid tripod should be used with a large top. It is a good plan to also have a small tripod 18 inches high. This is very useful when working in a tent or other shelter.

When working in a bird tent don't go to sleep.

The following notes on exposure refer to Imperial "Special Rapid" plates, with Goerz Dagor lens, an average light without the sun shining:—

Birds at rest on their nests in an open meadow—stop lens down to  $f/32$ : wind shutter right up, put mirror catch out of action, and give an exposure of three seconds, using the mirror itself as a cap or shutter.

Birds walking up to their nests— $f/8$  exposure, about 1-10th second.

Birds feeding, such as tits or finches— $f/6.8$  exposure, 1-25th second, or even 1-15th. Not quicker than 1-25th.

Small birds flying— $f/6.8$ , 1-500th second.

Large birds flying, such as gulls—1-300th second.

When making exposures of sea birds on such places as the Farne Islands or the Bass Rock, where the light is very strong, be careful not to over-expose. A third part of each of the exposures mentioned above might with advantage be given in such places. Imperial "Special Rapid" plates are quite rapid enough for the fastest exposures for birds flying over the sea.

Don't try to give rapid exposures in a dense wood—it is impossible.

Don't put the camera away for any lengthy period with the shutter set or with the tension spring wound up.

DEATH OF COLONEL LAUSSEDET.—It is with regret that we announce the death of Colonel Laussedat, whose work, as one of the pioneers in photogrammetry, was extremely valuable. He was a prominent member of the Société Française, and practically organised the public conferences of photogrammetry in 1891-2.

### THE INFLUENCE OF HEAT IN BICHROMATE PRINTING

ACCORDING to a recent paper in "Photographische Mitteilungen," a number of experiments have been carried out by W. Struck on the effect of heat rays in direct sunlight on the printing of pigment and gum papers. The temperature which a printing frame exposed to direct sunlight attains was found by filling a frame with wool, covering the latter with black paper, and laying on the paper the pigment paper and the glass negative. A thermometer was placed between the black paper and the pigment film. After five to twenty minutes the author found a temperature of from 35 to 67 degrees in the printing frame, whilst that of the surrounding air was 20 to 26 deg. A parallel experiment in which a paper negative was used gave a temperature only of 25 to 42 deg. This is explained by the fact that a very large proportion of the heat rays are reflected by the white paper.

In afterwards tracing the action which is exerted by the heat rays in the absence of light, the author laid a glass vessel with water at a temperature of from 40 to 60 deg. on a pigment of gum bichromate film. The latter showed at a temperature of 45 deg. in about fifteen minutes, or at about ten minutes at a temperature of 55 deg. A weak, scarcely-visible action in the case of gum paper did not manifest itself at a temperature of 60 deg. until twenty-five minutes had elapsed. At a temperature of 100 deg. the coating of gum became insoluble. Finally, the author studied the action in combination with artificial heat. He employed two printing frames, one of which contained a scale of gradations serving as a negative. It was exposed to a certain degree of heat, whilst the other printing frame was left at the ordinary temperature. For heating the former an iron chamber provided with a glass lid was used, being heated by a small flame beneath it, and being provided with a thermometer. The printing frame was suspended under the glass plate.

A print exposed at a temperature of from 35 to 40 deg. showed ten divisions of the actinometer in five minutes. One exposed at 40 to 50 deg. showed thirteen divisions, whilst the unwarmed pigment film showed only eight divisions. Gum pigment paper exposed at a temperature of 30 to 40 deg. showed only eight divisions. At a temperature of 45 to 50 deg. eleven divisions were shown, whilst the unwarmed paper showed six divisions only. It may, therefore, be taken from these experiments that increased temperatures without simultaneous action of light have a very slight influence on the sensitive film. At the same time the action of a simultaneous impact of sunlight is very considerably enhanced by heat. As a consequence the general view that the rays of direct sunlight cause the film to become insoluble is scarcely tenable, and any action which takes place under these conditions is actually to be ascribed to over-exposure, such over-exposure in its turn being due to the combined action of light and heat.

### THE RAPID PRODUCTION OF POSTCARDS.

APART from its evidence of the growth of the picture postcard trade in America, the following notes from the "Photo-Beacon," by Mr. G. W. W. Bucklin, may provide one or two hints of service to those who have to turn out cards at short notice:—

"All the rage!" If you don't think so ask the mailman. My experience has been a gradual development, first using P.O.P. until I was swamped; then experimenting with 2,000 c.p. arc light I obtained my present system. Some claim to make cards, develop, fix and wash in ten minutes and ask \$25 for the know how. The best I can do, and do right, is about thirty minutes. But as my method dispenses with an expensive lantern-camera, I have stayed by it. Two things are essential—fast-working plates and chemicals, and my special method of printing wet plates and dry paper. This last-named process is the only excuse for writing this article. It is as follows:—

(A) The fixed plate is taken from the hypo, rinsed and squeezed to a plain glass under water. The plates are then stood up at an angle of forty-five degrees to allow air bubbles to escape, as they will cause rings.

(B) The plates are then rubbed dry and the dry postal placed on plain glass side; print is masked with movable cut-out on the face of frame.

(C) Printing is done by the long rays of the arc light at a distance of about eight or ten feet. At that distance the shadow of the negative image is so sharp that the general public cannot tell between

prints made by this method and those printed after negative is in fact, they prefer this method, as the blemishes are not so pronounced. The exposure is made by a cord after the frame has placed on a rest where it will be absolutely still during exposure. side notes on the postal-card business I will add the following portion of my camera:—It is a sliding back, making three exposures a 5 by 7 plate, and is equipped with a portrait lens working exposures range from two to six seconds.

The light is an 8-arc, 2,000 c.p. street arc, furnished by city electric company, screened with 2 by 4 in. opaque oval, the light being diffused from 4-foot wing-shaped reflectors and the usual side reflectors.

Cramer plates are used, as they develop fast. For developer I use the tube M. Q. 'velox, for both plates and cards, using the same method on exposed end of cards, thus having the advantage of using a brush of fresh developer for each print.

Time required runs about:—Exposure, two to six seconds; developing, five minutes; fixing, five to eight minutes; printing, five to five minutes; fixing, extra strong bath, three to five minutes.

Rush orders are rinsed, placed in blotters, customers doing washing for themselves.

### PORTRAIT PHOTOGRAPHY.

THE ideal room for portrait-photography (says a writer in "Photo-Era") is the same as that chosen by the painter, a room the third or fourth floor, or even higher, with a north light. The reason why a painter chooses the north light is because it is a soft, even light, and does not fluctuate as does the light in a room where the sun shines into it some portion of the day.

Most of us cannot command such a room, and we must learn the possibilities and limitations of the one at our disposal. With w reflectors and properly adjusted screens one can secure almost any sort of lighting he desires, and, with care in manipulating his camera obtain excellent results.

If one has studied portrait work, then he is already well fitted to practise portrait-photography. If such is not the case, however, his best plan—lacking a teacher—is to buy photographs of some of the best works of the masters of portrait-painting and study well the posing and lighting of the subjects. Then with a certain picture model, choosing at first the most simple, both in composition and lighting, pose the subject and endeavour to have the lighting correspond as nearly as possible with that of the study chosen. If the first attempt is not successful—and the chances are that it will be—then try another and another from the same study until the result approaches in some degree the model.

For the beginner in portrait-work the most pleasing results can be obtained if the face is turned away from the light, as the shadow will give softness and roundness to the features. If the head is turned to either side care should be taken that it is not turned so far as to bring the muscles of the neck into prominence, as the effect is unpleasant. The lighting of the face should be so adjusted that the lights and shadows seem to melt and blend into each other without sharp definition between. This effect is termed the proper gradation of lights and shadows, and this treatment of the lighting distinguishes between the photographer with and the photographer without artistic training.

The hands are perhaps as difficult a part of portrait-photography as one encounters. They should be kept in shadow as much as possible, and in posing, the side, instead of the back, of the hand should be turned toward the camera. One should never try to arrange the hands of a subject. If the position of the hands does not seem pleasing, ask the subject to lift them and drop them again in his lap. The muscles of the hands when at rest should be relaxed, the sitter before a camera is all too prone to hold his hands stiff and rigid. The fingers should seldom if ever be doubled or shut, as this gives the effect of stubbornness to even the most slender hand. Sometimes it is a good idea to use a book or a small picture in the hand, choosing for the book a small volume with rough leaves in yellow or brown tones. The picture should be on a rough mount of dull gray or drab cream. Where use is made of a book with shiny leaves it gives a strong high-light where a high-light is not desired. The light should always be concentrated as much as possible on the face, the figure and accessories being subordinate in tone and decorations.

The sitter should not be allowed to look straight into the camera. The focus of the eyes on an object so near detracts from the expression.

sion, and the result is not so pleasant as when the sitter looks beyond the camera at some distant object.

The dress of men and boys has little of the artistic, but the dresses and draperies of girls and women are full of artistic possibilities. One point to remember is that the simpler the dress the more artistic will be the picture. If one wishes to make a picture which shall not lose its charm in after years, then use a very simple gown, and have the hair dressed loosely and in none of the exaggerated fashions of the moment.

In focussing for a portrait use one of the largest, if not the largest stop, focus on the eyes, then turn the lens outward just enough to do away with the sharp focus. The exposure varies with the light and with the rapidity of the plate. On an ordinarily bright day, with quick plates, an exposure of five seconds is quite long enough, but if the day is dull or the sitter placed some distance from the window, the exposure should be prolonged to from fifteen to thirty seconds.

Do not make your subject wait too long. Have everything in readiness, and work quickly. If one spends too much time in arranging and rearranging his accessories and posing and re-posing his sitter, both operator and sitter will become tired and the picture will be a failure.

Never being satisfied with one's work is the way to advance; though you do well, do not give up the idea that you can do better.

#### PHOTOGRAPHY IN SMOKE PREVENTION.

THE deleterious effects of coal smoke escaping into the atmosphere (says the "Lancet") have often been referred to in our columns, and the discharge of black smoke from a chimney has been made a statutory offence. The prosecution of offenders is, however, not infrequently difficult on account of conflict in the evidence as to the density of the smoke emitted. Writing on this subject in the Engineering Supplement of the "Times" of March 20, Mr. James Swinburne points out that the excellent smoke chart of the Institution of Civil Engineers is imperfect, because it is almost impossible to compare smoke seen against the sky with a shade on paper which is not only in close proximity to other darker and lighter shades, but is not really comparable at all. He says that this difficulty may be overcome by having the smoke scale made on glass or transparent celluloid which can be held up in such a way that the smoke can be compared with the progressive series of tints forming the scale. These scales might be standardised so that different observers might have exactly similar tints before them, and a further improvement would be to photograph the smoke scale together with the smoke which is to be tested. They then both receive the same treatment, and the smoke on one print is compared not with the smoke on another print, but with its own smoke scale. Thus, smoke on one print may be very light, the scale being very light too, so that the smoke corresponds with the scale at, say, 0.4, which means that the smoke stops four-tenths, or 40 per cent. of the light. On another print, taken by someone else at the same time, the smoke may look very dark, but the scale will look very dark too, so that the smoke will still correspond with the part of the scale marked 0.4. Mr. Swinburne further describes how a smoke scale, with its varying tints, is prepared on a photographic plate, and how different smoke scales can, for purposes of comparison, be calibrated in terms of their light-stopping power. He says that for photographing a column of smoke which is to be tested, a pocket quarter-plate camera does quite well, its only drawback being that the shutter has only one speed, which will probably be too fast for smoke photography.

#### SEEING WITH A FISH'S EYE.

THE British high school girl of scientific turn in search of instructive holiday entertainment for her seniors might try photographing the world as it appears to a fish. The Professor of Physics at John Hopkins (Baltimore) University, Dr. R. W. Wood (says the "Standard"), has shown how this may be done. Rays of light, as every high school girl knows, are bent by refraction on passing from air into water; and hence to an eye under water the terrestrial horizon appears lifted up so that the sky is compressed into a comparatively small circle of light. (The cone of light entering the fish's eye has, in fact, an aperture of only about 96 deg., though the rays within it originally came from a cone of 180 deg.) The appearance is

much as if the pond were covered by an opaque roof with a round window cut in it. Objects surrounding the pond must appear round the rim of the above-mentioned circle of light. The simplest way of seeing how they look from under water would, at first sight, appear to be to get into the water and try. But human eyes are not adapted for distinct vision under water, though a lens of half-inch focus held in front of one eye might help a little. By the use of photography, however, the affair becomes quite simple. There are various objections to employing an ordinary camera for the experiment. The following plan is recommended:—

Get a small pail, and a metal disc, perforated by a pin-hole, fitting into the pail rather over half way up. Lay the photographic plate on the bottom of the pail in the dark room, and fill the pail with clean water (both above and below the disc). The pail camera is then set on the ground, and the surface of the water covered with a sheet of glass to prevent ripples. There must be no air between the glass and water. The pictures obtained with this device are extremely interesting, but it will not work pointed horizontally. In order to represent things as seen by a fish through the glass sides of an aquarium, the following method may be adopted:—Take a water-tight box with an opening in one end. Make a pin-hole in the amalgam film on the back of a piece of looking-glass, and cement the looking-glass, glass side out, over the opening in the box. Bring the box into the dark room, insert the plate, fill the box with water, and put on the cover. Add a little more water through a small hole to displace air. Very curious results are obtained with this apparatus, which will photograph objects right up to the tripod, and those nearly due right and left, and directly over the camera. The marginal portions of the picture are, of course, distorted. When a straight row of nine men, side by side in a garden path, was photographed with the camera held 18 inches in front of the central figure, the straight path appeared bent into a semi-circle, and the end figures were reminiscent of "Pictures of pre-historic times."

Pointed downwards from a balloon the device would give a compressed bird's-eye view of the entire surface of the earth out to the horizon in all directions. Pointed upwards, it would photograph the entire sky, and might, therefore, be applied to serve as a sunshine recorder.

An article, with illustrations, on this same subject appeared in our contemporary, the "Photographic Monthly" of February last, page 50.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between March 25 and March 30:—

**FILMS.**—No. 7,132. Improved manufacture of photographic films.

A. J. Boulton, 111, Hatton Garden, London, for Société des Plaques et Papiers Photographiques A. Lumière et ses fils, France.

**COLOUR-PHOTOGRAPHY.**—No. 7,217. Process for the production of coloured photographs. John Henry Smith and Waldemar Merckens, 65, Chancery Lane, London.

**SHUTTERS.**—No. 7,235. Improvements in photographic shutters. Félicien Blanpain, 18, Southampton Buildings, London.

**DARK SLIDES.**—No. 7,268. Improvements in or relating to photographic dark slides or plate-holders. Albert Posso, 111, Hatton Garden, London.

**CINEMATOPHONES.**—No. 7,277. Improvements in cinematographs. Stanislaus Kucharski, 18, Southampton Buildings, London.

**CINEMATOPHONES.**—No. 7,376. Improvements in cinematographs. Claude Antoine Lumière, 7, Southampton Buildings, London.

**CHEMICAL SHEETS.**—No. 7,439. Photographic chemical sheets. John Edward Thornton, Altrincham, Cheshire.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**TONING SILVER IMAGES.**—No. 21,584, 1906. This invention is a simplification of the processes described in Specifications Nos.

18,370, 1903, and 10,898, 1904, manganous salts being now employed instead of manganic salts.

The new process is conducted by immersing a silver bromide positive or negative picture in a bath consisting of a solution of a manganous salt and ferricyanide of potassium, whereby the silver picture is converted into one consisting of manganous ferro-cyanide.

Baths of suitable composition are as follows:—

#### Example I.

100 c.c. of potassium ferricyanide solution of 0.5 per cent. strength.

20 c.c. of manganous sulphate solution of 2 per cent. strength.

15 c.c. of potassium bromide solution of 10 per cent. strength.

#### Example II.

100 c.c. of potassium ferricyanide solution of 0.5 per cent. strength.

20 c.c. of manganous sulphate solution of 2 per cent. strength.

#### Example III.

100 c.c. of potassium ferricyanide of 0.5 per cent. strength.

25 c.c. of manganous sulphate of 2 per cent. strength.

15 c.c. of potassium bromide of 10 per cent. strength.

5 c.c. of normal hydrochloric acid.

Instead of a solution of a manganous salt and potassium ferricyanide, a solution of manganous ferricyanide may be used. A suitable mixture is, for instance, as follows:—

#### Example IV.

200 c.c. of saturated manganous ferricyanide solution.

10 c.c. of potassium bromide solution of 10 per cent. strength.

It is advantageous to use a mixture of a manganous salt and potassium ferricyanide with a substance, like sodium tartrate, which forms complex salts with manganous salts. A suitable mixture, for instance, is as follows:—

100 c.c. of a saturated solution of manganous ferricyanide in a solution of sodium tartrate of 25 per cent. strength.

10 c.c. of potassium bromide solution of 10 per cent. strength.

The action of the baths can be hastened by heat.

The pictures obtained may be treated with an alkaline solution of potassium ferricyanide in the manner described in Specifications Nos. 18,370 of 1903, and 10,898 of 1904.

The manganous pictures may be coloured, if desired, in the manner described in the last-named specification, by means of suitable dyestuff formers. Besides the substances named in that specification, solutions of cobaltous salts may be used. Neue Photographische Gesellschaft, 27, Siemensstrasse, Steglitz, Berlin.

NEW "COOKE" LENSES.—No. 7,661, 1906. The invention relates to a new construction of "Cooke" lens, consisting of a negative

Fig. 1.

lens placed between two positive lenses of very unequal focal length; the power of the negative lens approximating towards 90 per cent. of the sum of the powers of the two positive lenses; whilst the radii of the separation between the second and third

surfaces are so mutually adjusted as to permit of the image of a distant vertical line keeping well defined without re-focussing right across the horizontal diameter of a flat plate subtending an angle of 70 deg. or more at the lens.

The author points out that the curves of focus of horizontal and vertical (radial and tangential) lines obtained with a "Cooke"

Fig. 2.

Lens of Series III. and of construction shown in Fig. 1 are as in that figure in which the abscissæ are enlarged three times for clearness. In the case of Series V., "Cooke" lens (fig. 2), the curves are as shown.

If one form of Cooke lens shows the characteristics of Fig. 1, and another shows the characteristics of Fig. 2, surely some intermediate form of Cooke lens may be devised whose image curves would approximately coincide with the focal plane C — P, and thus yield a flatter image with less astigmatism over a larger angle of view than any existing Cooke lens. This general idea led the author to further investigations into the causes of the image curves deviating in the manner shown from the ideal plane, with the result that he came to the conclusion that these curves are the resultants of corrections of a hybrid nature affecting the pencils of light refracted obliquely through the lens, that is, they result from certain residual obliquity and eccentricity errors varying as the square of the tangents of the angular distances from C, being opposed by contrary obliquity

Fig. 3.

and eccentricity errors varying as the fourth power (and in lesser degree 6th power) of the tangents of the angular distances from C.

Fig. 3 illustrates this. Let C — B be a curve whose abscissæ vary as the square of the vertical height from C, and let C — D be a curve in the opposite direction whose abscissæ vary as the fourth power of the vertical height from C, then at a

certain height we have abscissæ E — — b and E — — d equal. Now C — — P represents the focussing screen, and C the axial point, and C — — L the optic axis, the lens being on the left. There are certain errors in the lens of the order  $\tan^2 \phi$  tending to throw the image back from the lens and away from C — — P in degrees represented by the curve C — — B, but at the height C — — E there exists an equal and opposite error of the order  $\tan^4 \phi$ , tending to curve the image towards the lens. That is, the two sorts of error are equal at the height C — — E, but clearly unequal at all other heights, for between C and E the abscissæ of the curve C — — B are in excess of those of the curve C — — D, while at greater heights than C — — E the abscissæ of the curve C — — D rapidly grow the greater. Therefore, the curve C — — M — — E — — F is the resultant of the two opposing curves C — — D and C — — B. The resultant curve between C and E is at a maximum at M, the height C — — M being

$$\frac{C - E}{\sqrt{2}}$$

and the abscissa at M being

$$\frac{d - E}{4} \text{ or } \frac{E - b}{4}$$

Beyond E the resultant curve rapidly bends in towards the lens. It will easily be seen that this hybrid curve C — — M — — E — — F substantially resembles the dotted curve of Fig. 1 for the Cooke lens Series III. If the curve C — — D varying as  $\tan^4 \phi$  were on the right hand of C — — P, and the curve C — — B varying as  $\tan^2 \phi$  were on the left, then, of course, the hybrid curve C — — M — — E — — F would be turned the other way, and then we have the counterpart of the dotted curve shown in Fig. 2 for Cooke lens Series V. The corollary is, that if I can eliminate from a Cooke lens system the curvature errors of the order  $\tan^2 \phi$  and  $\tan^4 \phi$ , I shall then be able to obtain a flat image up to a considerably larger angle from the axis than is the case with Series III. or Series V. Cooke lenses. That being done it then becomes a question of bringing the curve C — — B of the order  $\tan^2 \phi$  down to the flat C — — P, in which there is no difficulty.

It can be shown that the chief origin of these errors of the order  $\tan^2 \phi$  and  $\tan^4 \phi$  lies in the second surface  $r_2$ , and in much lesser degree in  $r_3$  of Figs. 1 and 2. These surfaces are convex towards the stop. It would take a very long mathematical demonstration to prove this; but the broad argument is this; that certain corrections tending to curve the final image rapidly inwards towards the lens and varying as  $\tan^4 \phi$  and  $\tan^2 \phi$  arise in  $r_2$ , which rapidly increase in amount as the distance from  $r_2$  to the stop is increased. Not only so, but the third surface  $r_3$  also exerts an influence contrary to that of  $r_2$ , but  $r_3$  is nearer to the stop than is  $r_2$ .

In Fig. 2 the distance between  $r_2$  and the stop, and also between  $r_2$  and  $r_3$  is less than in Fig. 1, and we have the hybrid curve for a pair of tangential lines showing opposite characteristics in the two lenses. In these lenses the power of the negative lens is about 90 per cent. of the sum of the powers of the two positive lenses, but in various forms of the Cooke lens the relative powers of the two positive lenses,  $L_1$  and  $L_3$  are different. In those of large relative aperture the powers of  $L_1$  and  $L_3$  are about equal; Series III., Fig. 1, the power of  $L_1$  is 4.4 times the power of  $L_3$ , while in Series V., Fig. 2, the power of  $L_1$  is 51.8 times the power of  $L_3$ . It will be seen that the more the power of the positive constituents is concentrated into  $L_1$ , while the power of  $L_2$  remains constant, the closer must the front positive lens  $L_1$  be brought to  $L_2$  in order to get the spherical aberration balanced. Hence the suitable division of power between  $L_1$  and  $L_3$  is one indirect step towards getting the proper amount of separation between the contiguous surface of  $L_1$  and  $L_2$ , which is necessary to getting rid as much as possible of the curvature errors of the order  $\tan^2 \phi$  and  $\tan^4 \phi$ .

But the requisite separations or air space between  $L_1$  and  $L_2$ , in order to obtain the above, depends also upon the relative radii of curvature of the opposing surfaces  $r_2$  and  $r_3$ . Two Cooke lenses of the same relative aperture and focal length may have their front lens  $L_1$  differently shaped, one having its radii in the ratio +1 to +20, and the other +1 to +6, and there will be a

marked difference between the two lenses in this respect, that while the spherical aberration of oblique pencils may be very slightly overcorrected in the latter form of lens, yet in the former lens it will be so much overcorrected as to ruin the marginal definition. It is also of the greatest importance in order to avoid this latter defect that the lenses  $L_1$  and  $L_2$  should be kept as thin as possible. It is therefore highly important to keep  $L_1$  not only as thin as possible, but also as nearly tending to equi-convex as is consistent with the elimination of the curvature errors of the order  $\tan^2 \phi$ , although the two conditions are to a considerable extent antagonistic, and the more  $L_1$  tends to equi-convexity, the more will  $L_2$  have to be bulged backwards and thus tend to take the meniscus form, with its concave surface towards the stop, and the finished lens which I shall shortly describe has its back lens in that form. What I am aiming at is a Cooke lens so modified and designed that with an aperture of F. 6, if possible, it will give a flat or approximately flat image up to at least 35 deg. from the axis, curvature errors of the order  $\tan^2 \phi$  and  $\tan^4 \phi$  being as much as possible eliminated, while at the same time it will give reasonably good correction against spherical aberration for oblique pencils. As the chief feature of the lens lies in its image for tangential lines, or, in other words, its image formed by rays contained in primary planes, being approximately flat over as large a field as possible, therefore a very appropriate name for the construction is the "Primoplane" Cooke lens.

Below are the curves and other data for two different forms of this lens.

The equivalent focal length is supposed to be unity and the radii and other data are expressed as decimal fractional parts of such equivalent focal length, so that for a required equivalent focal length of say 10 inches, such figures would have to be multiplied by 10 in order to obtain the proper actual radii, etc., also in inches. The + sign indicates a convex surface, and the — sign a concave surface.

Primoplane lens, No. 1.

F  
Full aperture ———  
6.5

Glasses.

$L_1$ and $L_3$	$L_2$
Dense barium crown glass.	Extra light flint
$\mu D = 1.6053 \quad V = 59.3 \text{ (C to F)}$	$\mu D = 1.5372 \quad V = 47.2 \text{ (C to F)}$
$\mu G - \mu D = .01298$	$\mu G - \mu D = .01476$

RADII, &c.

$r_1 = +.169$	$r_2 = +1.272$	$r_3 = -.634$	$r_4 = -.157$
Central thickness =	.0316	Central thickness =	.005
Diameter =	.160	Diameter =	.145

$L_3$  (Meniscus)

$r_5 = -3.16$	$r_6 = +.527$
Central thickness =	.028
Diameter =	.160
Axial air space between $r_4$ & $r_5$ =	.0807
Total length over vertices of outer lenses =	.154

The front lens  $L_1$  must be screwed towards the negative lens  $L_2$  until the full aperture axial pencil of light coming from a distant point yields a focus substantially free from spherical aberration, or shows a little positive spherical aberration in the sense that the edge rays focus slightly shorter than the central rays. The field of this lens extends to fully 35 degrees from the axis.

The stop may be placed either behind  $L_2$ , as in Fig. 2, or else immediately in front of and grazing the front  $L_1$ .

Primoplane lens No. 2.

F  
Full aperture ———

Glasses.

$L_1$ & $L_3$	$L_2$
Dense barium crown.	Extra light flint.
$\mu D = 1.6053 \quad V = 59.3 \text{ (C to F)}$	$\mu D = 1.5420 \quad V = 46.8 \text{ (C to F)}$
$\mu G - \mu D = .01298$	$\mu G - \mu D = .01502$

RADIi, &c.			
$r_1 = +.202$	$L_1$	$r_2 = +.611$	$L_2$
Central thickness		$r_3 = -.4137$	$r_4 = -.1924$
Diameter		Central thickness	$r_5 = -.0045$
		Diameter	$r_6 = .171$

$L_3$ (Meniscus)			
$r_5 = -.719$		$r_8 = +.3595$	
Central thickness			$r_9 = .044$
Diameter			$r_{10} = .171$
Axial air space between $r_4$ & $r_5$			$r_{11} = .082$
Total length over vertices of outer surfaces			$r_{12} = .166$

$L_1$  is in correct adjustment with respect to  $L_2$  when the spherical aberration of the full aperture axial pencil is very slightly under-corrected, the edge rays focussing shorter than the central rays. The stop is best placed in front of and just grazing the front lens  $L_1$ . It can also be placed behind  $L_2$ , as in Fig. 2, but the angle of good image is not then so extended. With the stop in front the angular extent of passable image at full aperture is  $37\frac{1}{2}$  to 40 degrees from the axis, while with the stop placed behind  $L_2$ , the extent of passable image is reduced to about 35 degrees, even when the aperture of the front lens is reduced to F. 6.3.

Of course, any two of these lenses may be screwed together with the stop in common between the two front lenses, which will then face one another, and thus a flat field lens of large aperture will be obtained.

I have found in working out these lenses that there is a certain incompatibility between the condition of good correction against spherical aberration for the very oblique pencils, and the condition of continuous flatness of field for tangent lines up to a large angle of obliquity, or, in short, the primoplane condition.

So it is that in primoplane lens No. 1, while the primoplane condition is very closely fulfilled up to 35 deg. from the axis, yet the oblique pencils are considerably over-corrected for spherical aberration. On the other hand, in primoplane No. 2, while the oblique pencils are better corrected against spherical aberration, and the angular extent of good image is greater, yet the primoplane condition is not quite so well fulfilled as regards medium angles from the axis. The curve of best foci for tangent lines somewhat leaves the ideal plane in the neighbourhood of 30 degrees in order to come back on to the focal plane a little further away from the axis. Nevertheless, the image of a tangential line if focussed at the centre, will then, on rotating the camera, remain in fairly good definition right across a field of 75 to 78 degrees even at full aperture, so that the primoplane condition may be said to be practically fulfilled.

In both lenses the effect of screwing  $L_3$  nearer to  $L_2$  is to round the image or make it more concave to the lens; it also tends to outward coma and to pincushion distortion of straight lines, while screwing  $L_3$  further away from  $L_2$ , of course, has the opposite effects. Harold Dennis Taylor, Stancliffe, Mount Villas, York.

## Analecta.

Extracts from our English weekly and monthly contemporaries.

### Sulphocyanide in P.O.P. Development.

Mr. R. E. Blake-Smith (writing in "Photography" on "Certain Aspects of Silver Intensification") says, of the development of P.O.P. by the Paget process:—In this method one is always told to immerse the print in a 10 per cent. solution of potassium bromide after printing and before development. Now, merely immersing the print in potassium bromide solution will not, as a rule, convert all the silver other than silver chloride present into silver bromide. In the P.O.P. which one generally buys the soluble silver compounds have combined with the paper and gelatine to a certain degree, and in order to convert this combined silver into bromide a certain amount of some suitable solvent of silver compounds must be added to the potassium bromide solution. The best solution is:—

Potassium bromide	.....	$\frac{1}{2}$ oz.
Ammonium sulphocyanide	.....	10 grs.
Water, to	.....	5 ozs.

If ammonium sulphocyanide or other similar substance is not added to the bromide bath, the developing solution, which is here much stronger than in the first case, will decompose the combined silver producing yellow stains. I do not consider the development of P.O.P. at present a process of any real practical value, for the image obtained is not itself of a pleasing colour, nor is it suitable for toning to one.

### Control in Ozobrome Printing.

THE REV. W. DICK (writing on "The Ozobrome Process" in "The Amateur Photographer" of April 9), says:—A strong print may be made from a weak bromide print. To do this it is only necessary to add to the working sensitising solution a quantity of a 10 per cent. solution of ammonia.

In about six ounces of the working solution, not the strong solution as purchased, put 10, 20, 30, 40, 50, or 60 minims of the ammonia solution, and the vigour of the ozobrome will increase with the increase of the ammonia.

A flat ozobrome print may be made from a strong bromide print. To do this, proceed as above, only use a 10 per cent. solution of chrome alum in place of ammonia. Almost any degree of vigour of flatness may be had by adopting the above directions.

## New Books.

"Patents and Designs." Critical Notes on Mr. Lloyd-George's Bill. By Ernest Lunge and Bernhard Dukes. London: Stevens and Sons, Ltd. 1s.

The new Patents Bill now before Parliament will doubtless excite much controversy and be the predisposing cause of the appearance of not a few pamphlets on the subject. We believe the present one the first to be issued, and it is frankly antagonistic to the Bill. The authors say in their preface:—"Hidden in casual amendments of the present Act are daring innovations which completely alter the nature of a British patent and introduce the German system, while the provision whatever is made for the vast administrative apparatus entailed by the change. Apparently this change was neither intended nor grasped by those responsible for the measure, since Mr. Lloyd-George failed to allude to it with a single word. Other actions deprive enormous British vested interests, represented by British patents in actual existence, of their present legal protection. A patent may, under the Bill, be revoked on application by a member of the public to the comptroller, and the final appeal will go to a single High Court judge. At the same time the present system of revocation on petition to the High Court continues in force up to a limited number of grounds, and the practical result is anarchy and confusion. The Bill purports to be in aid of the poor inventor, against powerful syndicates, foreign or British; whereas in truth it provides unscrupulous syndicates with every conceivable means of "freezing out" an indigent patentee. Certain grievances have been brought to the notice of the Board of Trade, where British manufacturers had entered into embarrassing engagements with American patentees. The Bill insults the British manufacturer at large, placing him, in his dealings with any patented article, under similar disabilities to those of a prodigal minor. The reckless generalisation indulged in by the draftsman produces, the authors submit, the effect, that the tying clause in the lease of a public-house may be null and void, if the fixtures include one single patent lock or lever, and the section in question ceases to be of any practical virtue until it is applied with all the strict regard to its wording that would also make absurdities like the one suggested unavoidable."

This is a very strongly-worded indictment of the Bill, and one to which we prefer to reserve judgment until the Bill has been further discussed in Parliament. But meanwhile the pamphlet is of the greatest interest to those whose property or living is wholly or partially vested in patents.

PORTRAIT PHOTOGRAPHY.—A new edition of Herr Fritz Loesch's "Die Bildmässige Photographie" has been issued by the house of Gustav Schmidt, Berlin. The text has been revised and added considerably, but the chief interest of the book for English-speaking photographers is still in the large number of illustrative example photographic portraiture by leading Continental and some British workers. Herr Duhrkoop has liberally supplied the author with

specimens of his varied portraiture, and on account of its illustrations the book should provide suggestion for and incentive to any trait photographer who is approaching his work with an open mind, desiring to let his own work benefit from a study of that of others.

## New Apparatus, &c.

Heyde Universal Actino-photometer. Sold by A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C. A new and improved model of this actinometer has been submitted by Messrs. Staley, who are the British and Colonial agents for the instrument. In the new pattern the range of the instrument is eased so as to permit of its being used for exposures by lamp-light and other artificial light, as well as in daylight; also the exposure, when an orthochromatic screen is employed, is ascertained

the Heyde apparatus by placing the screen across the aperture of the instrument, a method which, we would point out, can only be capable if employed consistently in conjunction with the same kind of colour-sensitive plate. In use the apparatus is very easily and expeditiously employed by pointing the instrument upon the darkest shadows of the subject and rotating the disc which carries the prism until the detail is just extinguished. This gives a number on a scale, which number, when read against a scale engraved on the apparatus, gives the exposure for any given light. The apparatus is very lightly made in magnesium

## New Materials.

Crayon "Seltona" (Self-Toning Paper). Made by the Leto Photo-Materials Co. (1905), Ltd., Rangoon Street, London, E.C. "Seltona," an exquisite collodion self-toning paper which we introduced on its first appearance some year or two ago, has now been improved by a variety giving the toned effects which photographers are familiar with by the designation "cream crayon" as used first to bromide paper. We found not the slightest difficulty in obtaining, by fixing only the rich sepia which is characteristic of bromide paper or, by the use of preliminary bath of salt for a time ranging from five to ten minutes, a series of tones ranging from dark brown to purplish blue. Our own preference is for the tone obtained by simple fixation or for the very pleasing warm blacks which the paper yields on toning in the usual platinum bath, the use of this on practically giving the effects of gold-platinum toning without the expenditure of time on the first bath. In thus favourably improving the paper as we have found it, it may not be out of place to add that judging from the recent specimens of the ordinary matt glossy "Seltona," the makers have not been content with their action in the first instance, but have evidently sought consistently to perfect the paper, with the result that the present make, for memory serves us correctly, affords prints of a richness of depth surpassing the first issue of the paper. The prices of all grades are based on twenty-two quarter-plate pieces for one exposure.

## CATALOGUES AND TRADE NOTICES.

MESSRS. TAYLOR, TAYLOR AND HOBSON, LTD., of Stoughton Street Works, Leicester, have issued a list of the various makes of cameras on the market which are fitted with one of their well-known "Cooke" lenses, together with particulars as to size of plate, focus and aperture of lens, and price of the outfit complete, thus giving at a glance the initial information needed by the would-be purchaser. These outfits can be supplied through dealers or direct from the above firm, who will be pleased to answer inquiries relating to any cameras not mentioned in the list.

THE CRITERION WORKS, Stechford, near Birmingham, send us the full catalogue, just issued, of the printing papers prepared specially for the use of amateur photographers. The firm makes a particular feature of small sizes suitable for users of the smaller hand cameras. Dealers should also make a note of the very handsome showcard, advertising in large, raised, gilt letters, the firm's "Criterion Papers," and bearing a specimen print. The card is sent free to bona-fide dealers.

MR. A. H. BAIRD, of 33 to 39, Lothian Street, and 2 and 4, Brighton Street, Edinburgh, sends us a copy of his latest catalogue, which contains illustrated particulars of the photographic and scientific apparatus and accessories which may be obtained from this enterprising firm, which claims to stock "everything photographic," and a perusal of the list before us seems to bear out this statement. We commend the list to our readers' notice, and think they would do well to obtain a copy.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### FRIDAY, APRIL 12.

Leicester and Leicestershire Photographic Society. "After Treatment of the Negative." A. Newton.  
Tunbridge Wells Amateur Photographic Association. Members' Lantern Evening.  
Everton Camera Club. "Flashlight Group." Demonstrated. E. C. Alcock.  
North Middlesex Photographic Society. "Negative Making." L. Dick.

#### THURSDAY, APRIL 18.

Handsworth Photographic Society. "Some Portraits Connected with the Bacon-Shakespeare Controversy." A. J. Williams.  
Liverpool Amateur Photographic Association. "Stereoscopy." J. O. Wakelin Barratt.  
North London Photographic Society. "Elementary Portraiture." W. D. Atchison.  
Rugby Photographic Society. Members' Lantern Night. Annual General Meeting.  
Richmond Camera Club. Members' Print and Negative Competitions.  
London and Provincial Photographic Association. Exhibition of Lantern Slides. T. E. Freshwater.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held April 9, Mr. J. C. S. Mummery, President, in the chair. The Secretary announced that a number of daguerreotypes and of albumen prints made by Scott Archer had been presented

to the Society by Mr. F. Stanley Hogg, and on the proposition of the Chairman a vote of thanks was passed to Mr. Hogg.

A demonstration of the "Spectroscope" was then given by Messrs. C. P. Butler and E. J. Wall. Mr. Butler briefly reviewed the development of spectroscopy from the first observations of Newton to its establishment as a branch of science by Bunsen and Kirchhoff. Mr. Wall showed a number of spectroscopic experiments on the lantern screen. The effect of a narrow slit in sharpening the regions of the spectrum was demonstrated, as was also the formation of bright line spectra by the volatilisation of metallic salts in the arc. A table demonstration was also given of the absorption spectra obtained when the vapour of a given element surrounded a flame in which the element existed in a state of vapour. Mr. Butler dealt briefly with the formation of diffraction spectra, and exhibited the "echelon" grating of Messrs. Hilger. A vote of thanks to the two demonstrators brought the proceedings to a close.

THE SOUTH LONDON PHOTOGRAPHIC SOCIETY held its annual general meeting on April 3 last. The secretarial and the treasurer's report, which were adopted by the society, showed the membership to be about 200. The business accounts showed a slight loss on the working of the society for the year, chiefly owing to heavy purchases of books for the library. The hon. excursion secretary reported the increasing popularity of the excursions. The hon. treasurer then brought forward a motion that "owing to the great expense incurred by the society in awarding silver plaques at the annual exhibition, in future bronze plaques only be awarded in all classes, except the gold medal class. This motion was adopted unanimously. Mr. E. G. Ruckes then brought forward a motion that the committee insert, in exhibition entry forms the condition that no signature, monogram, or mark should appear on the front of exhibits which would disclose the identity of the exhibitor. Dr. A. R. F. Evershed and Mr. H. Creighton Beckett spoke against making any such arbitrary condition, as suggesting it was questioning the ability and probity of the judges, Dr. Evershed remarking that a fancy monogram or mark often gave balance to a picture as part of the general scheme, and he would not care to purchase an unsigned work. The motion, upon being put to the vote, was lost. Mr. W. Calder Marshall was then elected president for the ensuing year, and Mr. W. Llewellyn White, hon. treasurer, Mr. Gideon Clarke, 101, Calbourne Road, Balham, S.W., being hon. secretary. A hearty vote of thanks was then accorded the officers and committee for their work during the past year. The proceedings then terminated.

CROYDON CAMERA CLUB.—A capital smoking concert at the invitation of the President, Mr. A. E. Isaac, filled the bill last week, and a most enjoyable evening was spent. A host of outside friends and many members contributed to a varied programme, which included an excellent string quartette, an amusing little play, assorted comic songs, and recitations. Mr. Lepine Smith's highly trained and beautiful baritone was at its best, notwithstanding the smoky atmosphere. Mr. H. P. C. Harpur, the Club's leading pictorial artist, appropriately sang "Will o' the Wisp" and other songs in the best grand opera style. Messrs. McLennon and Vernon Smith proved that they were both possessed of pleasant tenor voices. Mr. E. A. Salt made billiard balls change colour and size, and cards glide down his sleeves by force of gravity, and fly up by force of habit, in quite a bewildering manner. Dr. Mees, to everyone's astonishment and delight, sang a plaintive love-song with such impassioned fervour as to almost bring tears to the eyes of some of his listeners. Considering the worthy doctor had strictly confined himself to lemonade during the evening (an example not generally followed), his "turn" was considered a remarkable performance. The President made all laugh heartily with "The Lay of the Last Minstrel," as did Messrs. Adrian St. Elms and H. A. Stapleton with their respective contributions.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held April 4, Mr. Burgess in the chair. Mr. H. C. Rapson lectured upon "Stand-Camera Work." For this work he said the stand should be strong and as rigid as possible. In some cases it was required very tall, as, for instance, in churches. He thought a tall stand opened out the near seats better, thus giving a better view. In some cases also, by using a tall stand, one could point the lens over the top of the screens of the smaller chapels, and thus obtain a full view of these interiors. For copying, a very low stand was very

useful. He used one of some three inches high for this class of work and was thus enabled to work in comfort upon a table or packing case. A tilting top was also a very desirable thing to have, because by use many subjects could be obtained that were otherwise impossible. The camera recommended was the square bellows type, for the reason that it gave extra rising front over the taper bellows.

When copying pictures it was often desirable to use a large black screen to do away with reflections. When copying black and white work it was well to give the longest exposure the black would stand, and not, as sometimes recommended, a short exposure; by doing greater contract could be obtained. P.O.P. prints required about one and a half times the exposure of black and white to obtain the best results, whilst glossy albumen prints required twice the exposure of black and white, and sometimes three times.

Mr. Human took exception to the remark that the taper bellows did not give the rise of the square pattern, and said that some make of taper bellows allowed the lens to be raised fully 1½ inches over the top of the plate. Such bellows, when fitted with the tabs and holder for drawing forward, were ideal.

Mr. Haddon queried whether the tall stand, was best for any class of work, and Mr. Human thought that the best position for the camera was such as the general public saw the view from.

A vote of thanks to Mr. Rapson brought the evening to a close.

## Commercial & Legal Intelligence

THE EASTMAN KODAK Co., of New Jersey, have declared an extraordinary dividend of 5 per cent. upon the common stock of the Company payable on May 1 to shareholders of record on April 15.

H. KRUGER AND SONS, LTD. (Photographers, Huddersfield), £600 6 per cent. debentures, created and dated March 18, 1898, charged on the company's undertaking and property, present and future, including uncalled capital, subject to £600 mortgage debentures, have been registered.

SUNDAY TRADING.—At the Burton Police Court on Thursday last Charles Bernard Warner and Richard Sergeant, of High Street, Burton, were charged with doing certain business, to wit, photographing on Sunday the 24th ult. Police Constable Evans stated that at 11 p.m. on the day in question he saw the defendants at the premises which were lighted with incandescent lights. He observed two persons, and then a group of four go in and go behind a screen to hide their photographs taken, for which they paid. When spoken to the defendants admitted that they were aware it was an offence against the law, but in some towns no notice was taken of it. With this advice they did not close the shop. They said they did not know what to do about it as their employer was away. The shop was kept open, and other persons were seen to enter it. Police Constable Bates also gave evidence, and stated that the shop was kept open until 8.30. At 8.10 he went into the shop and reminded those charged that they had been advised to close, and they repeated information that the employer was away. One of the defendants stated that the shop was advertised to close at ten o'clock, but they closed as soon as they could on that occasion—8.30. Defendants were fined 5s. and 11s. 6d. costs.

### NEW COMPANIES.

COSWAY GALLERY, LTD.—Registered March 18. Capital £10,000 in £1 shares. Objects: To take over the business of photographing portrait and miniature painters, etc., carried on by R. B. Hope, G. A. Hope, at 171, New Bond Street, W., as the Cosway Gallery, to adopt an agreement with R. B. Hope, G. A. Hope, and J. St. G. Kane. No initial public issue. Registered office, 171, New Bond Street, W.

LANCASHIRE AND CHESHIRE UNION.—At the quarterly meeting of the Lancashire and Cheshire Photographic Union, held at Elbow Street, Liverpool, on Saturday, the question of the annual excursion was discussed. An invitation to Barrow-in-Furness was received from the affiliated society in that district. The invitation was accepted and it was agreed to suggest June 15 to the Barrow Society as a convenient date.

## Correspondence.

\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\* We do not undertake responsibility for the opinions expressed by our correspondents.

### THE ENVELOPE SYSTEM OF CARRYING PLATES FOR EXPOSURE.

To the Editors.

Gentlemen,—I see your reply to "Dark Slide," p. 263. I think the inquiry may be from some one who has seen my system, in which the bags are cheap—some 20s. per gross for quarter-plate plan, although seven or eight years old, is not on the market. I made the changing apparatus for myself. If your correspondent desires it, I will give him every information on the subject.

CHAS. LOUIS HETT.

Springfield, Brigg, April 6, 1907.

### THE POISONS ACT.

To the Editors.

Gentlemen,—I beg to call your attention to the Government Poisons Act, which is about to be referred to a Select Committee, as affording a very favourable opportunity whereby dealers in photographic chemicals might obtain some concessions in the sale of poisonous chemicals.

I would respectfully suggest that you forward a recommendation to the following Government Departments: Treasury, Privy Council and Home Office (the latter will appoint the Committee), advising that poisonous photographic chemicals be relegated into a third schedule; the following being a suitable form of recommendation:—Notwithstanding anything in the Pharmacy Act of 1868 or in any other Act of Parliament, any person may sell any poisonous chemicals used in photography without incurring any penalty or liability, provided that such poisonous chemical or preparation is sold in a sealed wrapper, box, or other vessel, bearing in legible characters the name of the pharmaceutical chemist or a chemist and druggist registered under the Pharmacy Act of 1868 as the compounder or manufacturer of such poison or preparation, together with the name and address of the seller."

I would further suggest that representations be made to the above-mentioned Government Departments, urging that the administration of the Pharmacy Act be transferred from the hands of the Pharmaceutical Society to the local authorities, when everyone would get impartial justice, and prosecutions for mere trivial offences without giving any warning, would be at an end.—Yours truly,

W. HUNTRODS.

President, Drug Stores Association

of Great Britain.

Colbeck Moor, Leeds.

### BLISTERS ON BROMIDES.

To the Editors.

Gentlemen,—Perhaps my experiences will be of assistance to your correspondents.

Two weeks ago I had a fresh batch of paper from the manufacturer, coated on thin, rough paper. All the enlargements on this paper blistered, even if only left to soak in water. The addition of alum bath after fixing did not remedy matters. As an experiment, I tried the alum in the fixing bath. Still the same result. I then put the blame on the developer, metol-hydroquinone, having an idea the potassium carbonate was the cause of the trouble, so I ordered this developer for amidol, which contains no alkali, and since got perfect prints, free from blisters, even after washing with full force of the tap direct on the prints.

I remember six years ago having the same blister trouble, and adding alum to the fixing, which remedied matters, but the prints so treated went a dirty yellow colour within six months, although after fixing they were washed in running water for two hours.

The fault seems to be in the gelatine, which is readily attacked by an alkali, as prints developed with amidol were free from blisters, but after toning in sulphide bath the same trouble cropped up.—Yours faithfully,

E. F. SANDERS.

Sydenham House Studios, Domestic Street, Leeds,

April 9, 1907.

## News and Notes.

MESSRS. A. and E. STALEY and Co. inform us that they have now received a supply of show-cards for "Argo" paper, and dealers can obtain specimens of same for exhibition purposes on application to the above firm, at 19, Thavies Inn, Holborn Circus, London, E.C.

MR. W. J. BRISTOW will be unable to fulfil his engagement to lecture to the members of the Central Photographic Society on April 15, as previously announced. His place will be taken by Dr. J. H. Wilson, who will give a practical demonstration of the new "Oil-Printing Process," at Exeter Hall, Strand, at 7.30 p.m.

A WINDOW DISPLAY.—Mr. E. Dangerfield sends to the "Chemist and Druggist" sketches and notes on several recent displays which

he has made in Bedford, one of which is as follows:—This neat and effective display was a change from more fanciful tableaux. A small gilt frame (of my own manufacture) about  $4\frac{1}{2} \times 6\frac{1}{2}$  in., was fixed at a distance of two or three inches from the window-pane. A dozen or so of our leading counter-bills were pasted at upper and lower edges so as to form an endless band. This band passed over rollers in the frame and then to back of window over another roller, which was kept slowly revolving by the usual geared-down motor. This frame was surrounded by an assortment of dummy specimens of the medicines, etc., advertised on the bills. In this case all "machinery" was out of sight. It was fascinating to watch the gently moving counter-bills passing smoothly upwards through the frame—a sense of "expectancy" supplied the charm. The mechanical details were very simple—correct "alignment" was everything. After a few days another endless band was shown.

THE CINEMATOGRAPH IN MEDICINE.—The latest use of the cinematograph, according to Dr. Köhler, of Wiesbaden (reported by the "Pall Mall Gazette"), is an important part foreshadowed for it in conjunction with the X-rays in the practice of medicine. Dr. Köhler, indeed, has already invented a system by which cinematograph pictures can be taken of the breathing of sick and healthy persons, and some of these pictures were thrown, for the benefit of the conference, on a screen. The value of the system, Dr. Köhler explained, lies in the fact that it shows accurately the sympathetic action of the lungs and heart in inspiration and expiration. At the Hospital for Consumption and Diseases of the Chest at Brompton our special representative was informed that the general outline of the method explained by Dr. Köhler had been in use for some time; that is to say, the breathing of persons has been shown

by means of a series of ordinary photographs thrown on a fluorescent screen; and the use of the Röntgen-rays has enabled physicians to watch the diaphragm moving and to note the weak points in a patient. What, however, is new in Dr. Köhler's system is the application of the cinematograph, and this is undoubtedly a development. Hitherto the difficulty has been, in regard to photography, that the X-rays require a long exposure, and for pictures for the cinematograph the exposure that is needed is short. However, that difficulty, it was remarked, appeared to have been overcome. The advantage of cinematograph pictures, it was stated, would be that one would be able to reproduce those movements of the diaphragm which were revealed by the use of the X-rays. For physicians and students who could not be present at the moment when the rays were being used these reproductions would be of distinct value. And besides, it was added, it is always possible that the photographic plate is a little more sensitive than the eye, and that it will show you at once where there is something wrong.

**CO-OPERATIVE DRY MOUNTING.**—We see from the current circular of the Manchester Amateur Photographic Society that it has installed the dry-mounting machine of the Adhesive Dry Mounting Company, Limited, into its equipment. The example is one which other societies might follow, for the facility could not fail to be appreciated by members, and would undoubtedly act as a strong incentive to other photographers to join the society.

**SIR WM. ABNEY** has been elected an honorary member of the Photographic Society of Vienna.

**DEATH OF DR. AARLAND.**—We regret to have to announce the death of Dr. Georg Aarland, for many years a well-known teacher of photography and professor and principal of the photographic and photo-mechanical departments at the Imperial Academy of Graphic Arts and Bookbinding of Leipsic. Dr. Aarland was born in 1849. He was well known for his contributions on photo-mechanical and three-colour work, and was the author of a German translation of Verfassers's work, "The Half-tone Process."

**TANK DEVELOPMENT.**—It has been proved, by logic, by experiment, and by rule of thumb, time after time, that tank development does all that hand and eye nursing can do, yet there are thousands who refuse to believe what is known as a fact, and who still stick to the old, red light, hot stuffy room and variable formula methods.—C. H. Claudy in the "Photo-Beacon."

**"THE TRIBUNE" PHOTOGRAPHIC EXHIBITION.**—An exhibition of amateur photographs, photographic apparatus, cameras, and the latest developments of photographic science and art, is announced to be held at "The Tribune" Rendezvous, Bouverie Street, London, E.C., from April 29 to May 4, 1907, admission free daily. Prizes of £5, £3, and £2, in each of seven classes, are offered for competition to all bona-fide amateurs, the list of classes, together with the rules governing the competition, and the necessary coupon being published in "The Tribune." The competition closes April 22. The prizes will be distributed by Sir Benjamin Stone on May 3.

**THE UNITED STEREOSCOPIC SOCIETY.**—The following is the result of the annual competition for the best stereoscopic photograph:—Silver medal: Victor Selb, 42, Rue des Drapiers, Brussels; bronze medals (Class A): S. W. Shore, Barsbury, N., and W. T. Furniss, Sheffield; (Class B): J. C. Dancer, Manchester; (Class C): A. T. Snow, Walthamstow; (Class D): A. T. Mole, W. Hampstead. Hon. mention (Class A): Victor Selb and F. Low; (Class B): A. T. Mole; (Class C): Victor Selb; (Class D): T. Lambert.

**ROYAL INSTITUTION.**—A general monthly meeting of the members of the Royal Institution was held on the 8th inst., Sir James Crichton-Browne, M.D., F.R.S., Treasurer and Vice-President, in the chair. The special thanks of the members were returned to Sir Andrew Noble, Bart., K.C.B., for his donation of £200 to the fund for the Promotion of Experimental Research at Low Temperatures; and to Lady Kelvin for her gift of a statuette of the Rt. Hon. Lord Kelvin, G.C.V.O.

**THE L.C.C. SCHOOL OF PHOTO-ENGRAVING.**—A course of four lecture demonstrations on "Duplicate Plate-Making, Electrotyping and Stereotyping," will be given at the school, Bolt Court (on Thursday evenings from April 11 to May 2, inclusive), by Mr. J. A. Corey.

The syllabus includes:—Stereotyping:—An historical review. Past and present methods. Electrotyping:—A description of present day

practice. Some comparisons of American, English and Continental methods. Practical rapid electrotyping. The "Albert Galvano" process.

Succeeding these lectures will be a course of four lectures on the theory of photographic processes concerned in negative making, by Dr. C. E. Kenneth Mees, commencing May 9, and then a course of four lectures on three-colour and orthochromatic photography, by Mr. A. J. Bull, commencing June 6. Further particulars will be announced in due course.

**COMFORT FOR CATS.**—Puss is not everybody's idea of a good sitter, but at some time or other most of us amateurs have to turn the camera upon our own or somebody's else's cat. Some are reasonably willing to do what is wanted, but most cats would try the patience of Job. Here is a "wrinkle" (says a writer in the "Photo-Beacon") which I found worked well with a particular obstinate tabby. After all other attempts to get it to stop in front of the camera long enough to draw the shutter of the slide had miserably failed, I was seized with something like an inspiration. A cushion to which it was partial was placed in front of the kitchen fire—the only one in the house, for it was summer—and when warmed right through was put so that the model would be likely to retreat on to it at my next attempt. Puss, for a wonder, did exactly what I had anticipated, and, liking the warmth, settled comfortably down. I got three very good negatives, and could have taken a dozen after that without any trouble.

**THE DEATH OF MR. CHAS. GARDENER,** photographer, of Pitlochry, took place at Monlinear last week.

**THE R.I. AND THE R.B.A.**—These well-known initials constitute the nicknames of the Royal Institute of Painters in Water Colours, whose marble halls are in Piccadilly, and the Royal Society of British Artists, who have a less luxurious habitation in Suffolk Street. The present exhibitions of both are better in merit than any of recent years. The latter show has, in some way, got the right side of the Press since the election of its new President, Mr. Alfred East. The papers have spoken in "linked sweetness long drawn out" of its charms, whilst they have treated the other show with shorter shrift. This is scarcely fair, for both are making strenuous efforts to raise the standard of work, and whilst feebleness is found at each alike, the Institute, on the whole, shows the more clever execution. Its most remarkable work is, perhaps, Hassall's "Jury in Pilgrim's Progress," which displays unerring knowledge of character and a triumphant mastery over a difficult design. Edgar Bundy's crowded cavalier costume subjects are just what such subjects should be—amusing, lucid in tale-telling, and faultlessly drawn with gusto. The landscape that pleases us best is Watson Charlton's "River Tees at Barnard Castle," a noble subject, with a perfectly convincing effect of light. The water and sky could not be truer or more artistic. The Salute church at Venice in evening sunlight, is one of the finest things Arthur Severn has done, and we commend, also, to the visitor, F. Stuart Richardson's "North Sea Haven" as a water colour of charming execution. We have no space to mention other admirable pictures, but we are glad to note that Mr. Tilney has here one of the illustrations to his "Lohengrin," which we recently reviewed. The British Artists is a smaller show, and is mostly of oil pictures. Mr. East's "Winter's Dawn" is a great and masterly picture, perfectly true to the chilly grey of daybreak. We have only one fault to find with it—we cannot understand the bright flash of colour upon the middle distance—an isolated spot—where everything else seems to have missed the first sunrises. We dare not say it is impossible, but its possibility is certainly not made apparent. "The Suffolk Pasture" of A. Carruthers Gould (talented son of "F. C. G.") is in some ways the best landscape here, full of feeling and style. W. J. Laidlay's "Winter on a Norfolk Broad"—a sporting subject—is likewise noteworthy. So is the romantic and mysterious "Pool of Sleep," by Louis Grien. Mr. Frank Swinstead's expensive pastels are not hung in becoming company. Why has he given the same title to two? The usual terrors are in the little South Galleries; but they are all preferable to a ridiculous allegory, neither figure nor landscape, which occupies a place of honour in the Central Room. Of this the less said the better for the misguided artist. It proves what we have always suspected—that colour as well as form and design are lacking in his susceptibilities.

## Answers to Correspondents.

\* *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.

\* *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\* *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.*

\* *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED:—

J. H. Mumford, 22, Victoria Road, New Brighton. *Photograph of New Brighton Landing Stage, Showing Broken Bridge.*  
W. Webster, 21, Boundary Street, Lostock Gralam, Cheshire. *Photograph of the New Chemical Works, Lostock Gralam.*

**DAMAGED GLASS POSITIVE.**—I have a photograph taken on glass of a lady which I have somehow spoiled by rubbing the silver deposit from the face. It was placed behind another glass and I took it out thinking to clean it. There was a white deposit on hands and face. Can I do anything to it now? Can it be put in a silver bath, for instance, as it is the only one?—**POSITIVE.**

We suspect the picture is irretrievably ruined. However, as it is useless as it is, you might try intensifying it with acid pyro and silver, in the same way as in intensifying collodion negatives, with a view to making something of a negative that can be printed from. But we fear you will not meet with much success, though it may be worth the trial.

**RETOUCHING ("Progressive").**—From a professional retoucher's point of view your samples show no indication of retouching whatever, but only a few scratches here and there—mere dabbling. How can you expect to master retouching unaided in two months, and then secure a situation upon the strength—or, rather, the weakness of such utterly inadequate finish. We are afraid, "Progressive," you must be more moderate in your desires. The best advice we can give you is to at once take first-class instruction in the art.

**E. H. L. (Newport).**—You cannot do better than the Goerz-Anschutz camera, lens, and shutter, from C. P. Goerz, 4 and 5, Holborn Circus, E.C. Practically any of the ultra-rapid plates, selling at 1s. 6d. per dozen, quarter-plate size, are suitable for your purpose.

**BROMIDE TONING.**—I am undertaking to supply certain bromide prints of a tint resembling warm terra-cotta carbon, and find I can only get it with uranium. This, however, stains the paper and the whites, and washing does not entirely remove the stain. The very dilute ammonia bath seems to take the toned part of the image fog away before the stain is entirely removed. 1. I should be glad if you can tell me how to cure this? 2. Also, how long the toned prints should last framed up. Some of them would be in rather exposed positions, I believe, but the cost of carbon is too high? 3. Would a coat of celluloid in acetone help? I am to supply unmounted prints, and my customer will mount and frame them.—**D. B.**

1. A five grain per ounce solution of ammonium and sulphocyanide should remove the stain. 2 and 3. If given a coat of celluloid varnish (Zapon varnish), the toned prints will certainly last for several years.

**BARYTA PAPER.**—Can you give me the address of any firm that will supply me with the glossy baryta paper in rolls of one hundred yards, the same as enclosed, and what will be the proper term to give it?—**J. HARRIS.**

Otto König and Co., 27, Cross Street, Finsbury, could supply you from a similar sample.

**CONTINENTAL PAPERS.**—Will you kindly furnish me with one or two addresses of Continental papers, as I am desirous of advertising in same for a background painter?—**T. E. H.**

In France, "Photo Revue," 112, Rue d'Assas, Paris; in Germany, "Deutsche Photographen Zeitung," Weimar; or "Photographische Chronik," c/o W. Knapp, Halle a/S.

**COLOURED POSTCARDS.**—If I am not intruding too much on your space I would be obliged if you could give me the names of any firms where I can get views published like enclosed as I have some very good pictures and also orders to supply several wholesalers if I can get them direct, I think. If I am not mistaken, they are all or most of them printed in Germany, but I may be wrong. However, if you could find out for me where I could get them direct, as I can take any quantity, I would be deeply indebted to you. As the matter is urgent, if possible I would like an answer in Friday's issue.—**W. C. TIERNEY.**

The card is a gelatin half-tone in colour. Hood and Co., St. Bride Works, Middlesbrough, can supply you in quantities.

**FOG FROM PAPER SEPARATORS.**—1. At Easter I visited the Isle of Wight and made several exposures, all of which turned out passably, with the exception of one, and this was an entire failure. I am in the habit of separating my plates after exposure with a slip of paper, and writing the conditions of exposure thereon, as a guide to developing. This failure, which I enclose, as you will see, has received a distinct impression in fog of the paper slip. I shall esteem it a great favour if you could enlighten me as to the cause of the fog. A pyro-metol developer was used. 2. Also, could you advise me as to what kind of isochromatic screen to purchase for ordinary landscape work. Would it destroy the qualities of a good lens like Goerz Series III. to use a cheap screen?—**R. T. GREGORY.**

1. It is impossible to state the cause of fog without a chemical examination of the paper. It may be due to some injurious chemical, or, on the other hand, as has been often pointed out, some paper exposed to light becomes distinctly luminiscent. It is obvious, therefore, that it is impossible to state definitely the cause. On the other hand, one may assume that such very common wrapping paper as that used would be more than likely to contain hypo. or some other anti-bleach, which would at once account for the whole of the trouble. Nothing but the purest paper should be used for separating plates, and a preferable plan is to place two plates face to face and then wrap in paper. Details can easily be written on the paper for each plate. 2. Almost every maker of colour-sensitive plates issues special screens for use with his plates. For average work a screen increasing the exposure about five times would be correct. A great deal depends upon what is meant by a cheap screen, but in the ordinary way a good commercial screen has no practical effect on the good qualities of a lens, and even poor screens can be used by stopping down.

**COPYRIGHT.**—Is registration of a drawing or photograph sufficient guarantee that it cannot be copied or reproduced or printed by a rival firm, on china? What I wish to know is, if registration of drawing is complete protection from copying or reproducing for sale (without permission of proprietor) on anything?—**G. GUTHRIE.**

Yes, it is complete. Reproduction of a work by any other graphic process, or in any other form, is held by the Copyright Act to be infringement. Reproduction on a support such as china would certainly be infringement.

**TIME DEVELOPMENT.**—1. As one much interested in time development, I should be glad if you would give your opinion on the statement attributed to Colonel Houdaille in the "Journal," April 5, 1907, page 29, with regard to time allowance for change of temperature. 2. Do you think 5 per cent. correct; and, also, does it apply to all developers and all plates? 3. May I point out that the statement is mathematically vague, as a 5 per cent. decrease after a 5 per cent. rise would not produce the original time. Should it be: Add 1.20 to time for decrease of 1 degree, and subtract 1.21 for similar increase; or: Add 1.19 and subtract 1.20. Has not M. Clerc made an extra special mess of it by failing to calculate degree by degree; for if he calculated for a 20 degrees rise, by his method he would

reduce development 100 per cent., which would be very quick indeed?—Q. S.

1. M. L. P. Clerc correctly quotes M. Houdaille, whose original paper runs as follows:—"A variation of 1 deg. C. in the temperature of the developer corresponds to a variation of 5 per cent. in the opposite direction in the appearance of the image and in the total time of development. This rule holds good between 10 and 25 deg. C.

Taking as unit the time necessary at 15 deg. C., it is only necessary to add or subtract 5 per cent. for each degree of difference. Thus, if a negative at 15 deg. C.

Appears in ..... 60 sec.

And is completely developed in ..... 300 sec.

these times for a temperature of development of 23 deg. C. must have subtracted from them 40 per cent., thus giving—

Time of appearance ..... 36 sec.

Total time of development..... 180 sec.

2. M. Houdaille does not explicitly state whether the rule holds good for all developers, but implies that it does. 3. We are aware that the rule is not mathematically exact; but it was not advanced, we imagine, as anything more than an empirical guide. We should say that if it holds good, as claimed by M. Houdaille, the accuracy is quite sufficient for practical work.

E. S. D. (Hindhead).—Messrs. Newton and Co., 1, Fleet Street, London, E.C., are the most suitable people we know.

D. L. M.—Some of your specimens show good taste in posing, and in some of them, particularly those of the men, the lighting is well managed, and evidence shown of an appreciation of, and power to manage, strong lighting. The children's portraits are also well and softly lighted, but those of the ladies, in our judgment, are not what we call average good portraiture. The pose and lighting in nearly every case are too theatrical. The retouching in every case has been done with discretion. We can give you no idea of the salary you ought to ask, since we have no information as to your quickness or personal qualities. "Camera Craft" is issued from 1915 Post Street, San Francisco. Messrs. Dawbarn and Ward, 6, Farringdon Avenue, E.C., can supply you in this country. The American price is 10 cents (5d.).

STATISTICS.—Will you kindly let me know through the "B.J.P." column the name of any firm or agency who would be likely to furnish full particulars as to population, industries, and general information of any particular town in England, with a view of successfully opening a photographic business, or where this information is to be obtained?—BUSINESS.

Any good modern geographical gazetteer will give you the information. You will probably be able to see one at your local reference library.

A. GATES.—We have not reviewed the lamp. From what we hear, it is an excellent enclosed arc.

J. CLAUDET.—The result is certainly very good; not, in our opinion, for the tone obtained, which could be got by other baths, but for the great economy. We should certainly think the bath would be worth putting on the market, but we should strongly advise you to have it tested by others as to its powers and that, with several different brands of P.O.P. If you care to send us a sample of the bath we shall be glad to try it, and we will, of course, report upon it when it is on the market.

R. D.—You need not sell the negatives unless you wish to do so. If you sell them without transfer of the copyright, the latter expires. It is difficult for us to name a price, but as the parties have offered to purchase, we should say 7s. 6d. each. We will answer your carbon query next week.

BLEACHING BROMIDES.—I shall thank you if you can give me any information about the following: Say you have a bromide print and you make a pen-and-ink sketch on it, how would you take away the print and leave the ink sketch only?—J. B. W.

A solution of mercuric chloride will answer, or, better, a mixture of potass cyanide and iodine, as used for clearing bromide prints, but considerably stronger.

LENS FOR INTERIORS.—Can you please advise me what kind of a lens to use when photographing the interior of engineering works, so as to give the works the appearance of a long distance?—X. Y. Z.

A wide angle lens will give the buildings the appearance of

being much larger than they actually are, say 5 or 6 inches focus on a whole-plate.

BROWN TONES ON BROMIDES.—Can you give me a formula whereby I can tone bromide postcards to a good brown colour, other than by the hypo-alum? Is the metol-hydroquinone developer the proper one to use if the cards are afterwards to be toned brown? By a "brown" colour I mean the usual P.O.P. brown colour.—P. CARDS, BROWNTONE.

A pure brown tone is not very easy to get. The ferricyanide sulphide process will give you a rather warm sepia brown, but we think you might try the copper toning formula given on page 988 of the "Almanac," adding, say, an equal bulk of water to the mixed solution to slow the action, as the brown tone is obtained at the first stage of the process. We should say that if the tone satisfies you it will be far better to use the sulphide process as given immediately before the copper formula referred to.

BOOKS.—Kindly mention publishers and prices of Prof. Silvanus Thompson's translation of "Lummer's Optics" and Mr. Denn Taylor's "System of Applied Optics." Also, if known, publisher and price of "Lummer's Optics" from which Prof. Thompson has translated.—W. WASHAM.

"Photographic Optics" (Silvanus Thompson), is published by Macmillan at 6s. The German "Lummer" is published by Vieweg, Brunswick. The price, we think, is about M.12 for the volume containing the photographic section. The "System of Applied Optics" is issued by Macmillan, price 30s.

INFRINGEMENT OF COPYRIGHT.—Since the registration of photographs of wreck, executed by you in March, 1907, a firm of postcard publishers have taken the liberty of coming to me for some photographs of same, and reproduced them in penny card form and supplied shops all round me. Since these penny cards have been issued my sales of 2d. photographs have dropped from 700 cards per day to something like 25 per cent. of this number, and I have had several trade orders cancelled, of order of 500, and several other small orders. The firm in question I have written to, and threatened them with proceedings, unless they make an immediate compromise. Since my letter a week has elapsed, and I have not heard from them. Herewith I beg to ask if you will kindly favour me by advising me the best course to take. In case I take proceedings, shall I have to show a copy of the registration?—M. H. J.

Of course you will have to prove registration. We should say you have a fairly good case. We should advise you to put in the hands of the Professional Photographers' Association (which we hope you are a member), which would, no doubt, be able to come to a settlement; or you had better place the matter with your solicitor.

CHROME ALUM DEVELOPER.—Some two or three years ago you gave a formula in the "B.J." of a patented developer in which chrome alum was used to give hardness to the film. I should be glad if you could give me the reference to this, which I have been unable to find.—A. J. KNOX.

We expect you refer to Patent No. 9,116, 1905, published in our issue of January 5, 1906.

ESSEX.—The cost is about half, but present conditions are not in favour of the use of collodion emulsion.

\* \* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

An exhibition of photographs, to be added to the collection accumulated by The National Photographic Record Association, is opened at the "B.J." Offices. A brief review appears on page 290, on page 287 we refer to some matters which appear of importance to photographic record work.

The Professional Photographers' Society of New York, under the presidency of Mr. Pirie Macdonald, held its Convention a fortnight ago. Our correspondent describes some characteristics of the meeting, and we publish the presidential address. (P. 288.)

The Eastman Kodak Company is to be congratulated on its balance sheet for 1906, just issued. A dividend of 17½ per cent. on the ordinary stock has been distributed. (P. 295.)

We regret to announce the death of the Rev. T. Perkins, an enthusiastic photographer of the old school, and a frequent contributor to our columns. (P. 293.)

The calculation of development time for different temperatures of developer is discussed in our correspondence columns. (P. 300.)

The Jena works of Schott and Genossen are stated to have succeeded in preparing yellow glass for orthochromatic filters which is a great advance on existing glasses. (P. 292.)

In reference to the paper read before the Optical Society last winter "The Measurement of the Times of Photographic Shutters," by de Graaff Hunter, we publish a letter from Mr. Kershaw, of Leeds, claiming prior publication of the method. Mr. Hunter's reply is also published. (P. 301.)

A system of colour projection is amongst the patents of the week. (P. 295.)

New developers derived from benzole have been examined by Dr. King. (P. 291.)

## EX CATHEDRA.

**Hand-Camera Orthochromatism.** It is not often that the reproductions of photographs which appear in photographic journals are commendably pictorial and at the same time informative on technical points, but these two qualities are possessed by four landscape photographs which are reproduced in the current number of "Photographische Welt." Their author, Herr Robert Marx, is an enthusiastic advocate of orthochromatic effect, and these particular examples show the excellent results obtainable with a colour-sensitive plate and screen with exposures short enough to permit of moving objects in the subject. With the commercial plates now available there is no excuse for the unharmonious hand-camera photographs which are so largely the result of non-orthochromatic rendering. The user can take his choice between plates which are highly orthochromatic and require only a 1½ or 2-times screen, and others which, while more sensitive, are less so to colour, requiring therefore a deeper screen. It amounts to much the same in the end, and means that the hand-camera worker may obtain full orthochromatism in his negatives, yet with exposures such as he would give to a plate usually classed as of "medium" speed.

\* \* \*

## For and Against the Reflex Camera.

Every one who has been fortunate enough to have seen much of the hand-camera work of Mr. Jas. H. Sinclair will be compelled to respect what Mr. Sinclair

has to say on the choice and use of a hand-camera, and therefore the hints on this subject contained in the catalogue which we review on another page can be recommended to those in need of the straightforward, unvarnished opinion of an expert of the respective merits of different types of hand-camera. Though we may feel the temerity of the act, yet there is one point with which we cannot fall into agreement with Mr. Sinclair, and that is in his preference, quite apart from price, of the box scale-focussing hand-camera for that of the reflex pattern. Granting the lesser complexity—and therefore lesser liability to "go wrong"—of the former instrument, we cannot quite understand how Mr. Sinclair, experienced hand-camera worker as he is, should give the preference to the scale-focussing instrument on the ground of more inconspicuous working. The reflex, we would submit, may be used equally well as a scale-focussing camera by first focussing upon the spot which a figure is to occupy, and then shutting down the hood to await events. This is by far the most common method in scouting with the hand-camera, and one which, to our thinking, the reflex permits just as well as its scale-focussing prototype, whilst on almost all other occasions it is infinitely more certain. We certainly agree with

Mr. Sinclair that a method involving the examination of the focussing screen is not the best for figure study work, and if our memory serves us correctly we have seen reflex cameras by Messrs. Newman and Guardia with a scale affixed for focussing in the ordinary way, although one or two recent models which we have examined do not carry the focussing scale; yet it is an addition which might well be made without depreciating the camera in the least, while at times it would prove of real value.

\* \* \*

### The Misuse of Chemical Equations.

Many photographic writers are fond of translating photographic chemical reactions into equations, regardless of the fact that such an equation proves nothing, and conveys no information unless the truth of the equation has been proved by analysis. The majority of the reactions that occur in photographic processes are of a very obscure nature, and in many cases they relate to compounds that no chemist can pretend to understand. Equations are then purely speculative, and their only use is as speculative bases of future experiments. Thus, a writer in a contemporary, in discussing the use of the potassium bichromate and hydrochloric acid bleaching bath, says: "The action taking place is represented by the equation:—

That is to say, silver + potassium bichromate + hydrochloric acid gives chromic chloride + potassium chloride + water + silver chloride. Out of the number of equations that might be invented to describe the reaction, this is the most plausible at first sight, but it is also the easiest one to disprove, for the chromic chloride cannot be found, while it is very doubtful if the silver chloride formed is truly represented by the formula  $\text{AgCl}$ . Instead of chromic chloride one finds one of the obscure chromium oxides, which no one knows much about, and which, as yet, have no reliable formulæ of their own. There is little reason to doubt that in the bleaching solution mentioned above potassium chlorochromate is formed in accordance with the equation:—

But even this cannot be absolutely proved, and the further reactions with silver can only be guessed at.

\* \* \*

### A Purely Business Matter.

Our readers who constantly have transactions of a business character may be interested in a recent case in which judgment was given on a point in regard to which better business men than are many photographers are very likely incompletely informed. It is not uncommon to see on accounts the statement that "interest will be charged on the amount of unpaid bills." Such an intimation, however, unless both parties have agreed to such an arrangement, has no basis in law, and relies for whatever effect it may have upon the recipient on his amenability to pure and unadulterated "bluff." The practice is one which is not likely to be adopted by reputable firms, but nevertheless it may be well to pen this reminder of its true character. A case recently tried in Dorset is the most recent of many in which the illegality of the threat has been upheld.

\* \* \*

### The Latent Image.

Considerable attention has been directed in recent years to the nature of the latent image, but the sub-haloid theory has so far held its own, notwithstanding the assaults of theories based on electro-chemical and structural change. In the paper,

which we recently published, by Dr. Homolka, the existence of silver per-bromide is assumed, and the experiments with indoxyl and thioindoxyl certainly seem to warrant so much assumption. At a meeting of a chemical society recently held at Bremen, Dr. Hans Herzog also attacked the subject, and whilst the full text of his paper is not yet available, enough has been published to show that he considered the formation of the familiar silver sub-bromide an impossibility. His chief reasons were the fact of photographic action taking place at the temperature of liquid air, a degree of cold at which almost all chemical action ceases. The theory of valency also precluded such action. Dr. Herzog inclines to the structure theory, and incidentally, it may be remarked, gives as the formula for unexposed silver bromide  $\text{AgBr}_3$  or  $\text{AgBr}_6$ . It is obvious that if these formulæ can be accepted the formation of Homolka's per-bromide  $\text{AgBr}_2$  or  $\text{Ag}_2\text{Br}_4$  is quite feasible.

\* \* \*

### The Appreciation of Distance.

Among the most remarkable blunders made by optical writers, from the stating of Brewster downwards, perhaps the most is the theory that we estimate the distance of a point by the angle of convergence of the axes of the two eyes is the most remarkable on account of its extreme absurdity. Imagine the eyes to be converged on to one point at some particular distance. The theory then is that we can obtain an idea of the distance of that point by the magnitude of the angle of convergences; but this angle is in the same plane as the eyes, and consequently its apparent magnitude is quite indefinite quantity. A variant of the theory is that we cannot estimate the absolute distance of one point in this manner, but can estimate the relative distances of two different points by comparing the relative angles of convergence. This is another obvious absurdity, seeing that we cannot estimate the apparent magnitude of either angle and therefore cannot compare them. The only kind of visual angles that can be estimated by, or compared by, the eye are those that have an apex at the eye. In the triangle formed by two eyes and an object we cannot estimate even the angles at the base, for each eye is invisible from the other, hence the whole triangle is quite indeterminate. The only angles that we can estimate and compare are visual angles subtended by two visible object points, and this is the fundamental optical fact that governs the conception of distance in binocular vision, either with or without a stereoscope. If the eyes are regarded purely as a pair of optical instruments, our visual conception of distance is limited solely to the recognition of differences in apparent distance. We can only see that certain points are nearer or farther than certain other points. We cannot determine the magnitude of the differences, and cannot estimate the absolute distance of either point; nor even the ratio of two different distances to one another.

\* \* \*

### Insuring Photographic Assistants against Accidents.

The new law with regard to employers having to compensate employees for accidents which the latter may happen to meet with during their employment will certainly apply to photographic assistants, both male and female. The compensation which, according to the law, is to be given is certainly very liberal, and such a many photographers would have great difficulty in paying. Therefore it will be well for some to consider the question as to whether they should or should not insure their employees against accidents, seeing that the insurance companies grant policies at such low rates as they are not doing. Some may ask, What risks do photographer assistants run? They are not many, though they may have serious consequences, for which the employer will be responsible.

An assistant, for instance, goes up a pair of steps something to the studio blinds, and falls, breaking a leg; the employer would have to pay the whole or part of the wages while he is disabled, and possibly give very substantial compensation for the injury. Or, should a printer cut her finger in trimming prints, and blood poisoning supervene, her employer would have to pay the compensation. Very serious results frequently follow from trivial causes, but the employer will be held responsible. We should advise all our readers, who are employers of labour, to get the new Act and see from it what responsibilities are, and then judge for themselves whether it is worth their while to insure their assistants.

## NATIONAL AND LOCAL PHOTOGRAPHIC RECORD.

An exhibition which is opened to-day at our offices will, we hope, by many photographers engaged or interested in the work of photographic record to which Benjamin Stone and his colleagues of the National Photographic Record Association have so consistently devoted themselves. Our aim in holding the exhibition is understood from the few notes on the exhibits which follow the present article, but we are to seize an appropriate occasion to remark upon those which, it seems to us, are of importance to all bodies which are at present engaging or about to engage in the very desirable work of photographic record. We may be allowed to preface what we have to say by an expression of satisfaction at the constant increase in the number of associations whose first aim is the making and assemblage of photographic documents, including the buildings, customs, and people which must so readily disappear in the process of time. Nearly ten years ago, when the National Photographic Record Association was established, there was but one similar body, the "Photographic Survey of Warwickshire," the inception of which was also the act of Sir Benjamin Stone, who is at the present time its President. In the meantime, similar organisations in various parts of the country have been brought into existence—in most cases through the action of local photographic societies—and the propagandist work in record photography has been carried on by them. It was not taken up, as it was in some cases, directly by a photographic society. Turning to the last edition of the "British Journal Almanac," we find that the official responses to requests for information as to these survey parties place the number of the latter at seven, representing respectively Edinburgh, Essex, Kent, Surrey, Sussex, Warwickshire, and Worcestershire. We believe that, with the one exception, are actively continuing their work. And we are further glad to hear that contributions to the same object are being systematically accumulated by photographic societies which have not evolved separate bodies to devote themselves to record work. Yet the total of these gratuitous activities is far from adequate for the field which remains to be dealt with, but persistent application in season and out of season of existing societies must result in the gradual accretion of other helpers in the task. There is every encouragement in the fact of the really considerable work already done by the National Record Association without the aid of any particular scheme of organisation and from the efforts of a small number of photographers.

We commend photographic record to every photographic society, however small. It should form an incentive to co-operation among the members of which many a society stands in need. Fortunately the work does not call for any special qualification beyond the ability to take a photograph and the readiness to receive a hint from an antiquarian adviser as to the most essential features

of a subject of historical interest, and therefore it may be employed to enlist the services of the many photographers who possess neither the inclination (nor the temperament alleged to be necessary) to pictorial work.

At the same time, it is obvious that societies can do very little individually in comparison with their possibilities when they are joined together for a given purpose. It would be well if any of those whose executives feel a disposition to engage in photographic record would communicate with neighbouring associations, say those in the same county, suggesting the desirability of their uniting in the formulation of a scheme in which would be a place for each separate body. Such a proposition would most probably lead to the formation of an association specially devoted to record photography; and the fact that nearly all the existing work is at present done by associations modelled on these lines suggests that they are the best to follow.

We see in the local development of record work the surest hope that this important application of photography will be carried on within a widening sphere. There is every reason, as Sir Benjamin Stone pointed out at the last annual meeting of the National Photographic Record Association, for developing the establishment and extension of local collections of record photographs. In the majority of cases they are more readily accessible than one of the large dimensions which a national collection must inevitably assume, and further, the stimulating effect on photographers to carry on the work to completion is bound to be greater when the fruits of their predecessors' labours are to be seen and studied.

We commented some months ago on the necessity in such work as this of having a scheme of classifying the items in the collections which shall be both a guide to those which have already been acquired and at the same time allow for the addition of other photographs and subjects. The actual method of storing the prints requires to be very carefully considered, with a view not only to present convenience, but to adaptability to future accessions. We suggest, as we have suggested before, that the existing record associations might do worse than appoint a small committee to inquire into the best methods and present a report. If this were done, the suggestions and information rendered available to each society could, with certain possible modifications, be readily applied in the respective cases.

It need hardly be said, in conclusion, that the executive of the National Record Association, in the person of its honorary secretary, Mr. George Scamell, has always given every encouragement and help to those who have been induced to contribute their quota to the establishment of survey work in different parts of the country, and we know of no better advice to offer to those in need of assistance than to refer them to Mr. Scamell, who throughout his association with the N.P.R.A. has shown his desire to advance the work to which he himself in no small degree has contributed.

**CHANGE OF ADDRESS.**—The firm of Gilmer and Co., successors of Clément and Gilmer, 140, Faubourg Saint-Martin, Paris, announce that their warehouses, offices, and workshops have been removed to 21, rue Henri-Monnier, Paris, to which address all orders and correspondence should be directed.

**TURIN PHOTOGRAPHIC EXHIBITION.**—An International Exhibition of Artistic and Scientific Photography will be held at Turin in May, 1907. There will be two divisions, one for amateurs and the other for professional photographers. Artistic photography will include figure, landscape, marine, flower, and animal pictures. Scientific photography will consist of microphotography and astronomical photography. Applications for space will be received until April 30, and the objects themselves until May 15. Applications can be made to the office of "La Fotografia Artistica," Rue Accademia Albertina No. 1, Turin.

## PROFESSIONAL MATTERS IN AMERICA.

WE publish below the first instalment of the report of the Conference of the Professional Photographers' Society of New York, held in the Assembly Hall of the Metropolitan Life Insurance Company Buildings, under the presidency of Mr. Pirie Macdonald. We have commented in recent issues on some of the promised features of the meeting, and the account from our New York correspondent which we print below will afford a first-hand idea of how the plans of the society have been fulfilled in practice. There is every evidence that the very strict lines on which the convention has been held have fully justified the

executive in their action. No member was admitted who not paid his subscriptions, yet the attendance was a record. A single-picture exhibition, to which each man contributed, for example only of his work, totalled up to 200 exhibits, in addition to which there were selections of photographic portraits by British, French, and German professionals, the latter not being represented by the versatile and cordial Herr Dührke, who, busy man that he is, can always find time to take part in movements for the improvement of the photographer's business status in whatever country of the world that movement takes place.

### A PROFESSIONAL PHOTOGRAPHERS' CONVENTION IN NEW YORK CITY.

*By a New York Correspondent.*

New York is no more to be confounded with New York city than is Yorkshire with York. The city is merely the largest one in the State; but the State itself is about the size of England. Photographers drawn from all over the State have been meeting in their chief city to discuss their craft.

A couple of hundred of photographers are to-day drifting homewards, and talking to each other about the greatest convention "that ever was."

Many—if not all—American conventions have been the greatest ever, but the one just closed has presented some features both novel and commendable, and worthy of note by English photographers.

and on this levy the members have paid their way, apparently given themselves good value.

"Paid their way" is worth passing notice. The all but universal method of running a convention in this country is to make the merchant or dealer pay. Large material manufacturers have contributed lavishly to funds; and the first that most people hear of conventions is an offer of advertising space, at a fancy price, in the programme or catalogue to be issued. The New York photographers have preferred to ignore the advantages of this revenue, and take instead added independence.

The convention places as its first object the betterment of

*Photograph by]*

Hall of the Metropolitan Life Insurance Building, in which the P.P.S. of N.Y. Convention was held.

*[Byron, N.Y.]*

Most conventions have been an annual blaze of glory, when photographers have gathered together for a few days of talking and pleasuring, and have then scattered to their homes for twelve months of solitude. New York State—there are sixty counties in the State—has divided itself into local sections, and these sections have held monthly meetings, where fraternity has been kept alive, and where matters of immediate interest have been discussed. As a result more than two hundred paid-up members were on the roll when the convention began, and the rigidly enforced rule of no participation except for paid members has swelled the number with those who paid cash at the doors. The annual subscription is three dollars—twelve and sixpence—

business condition of the master photographer. Art for art's sake and the glory of the craft retire to the rear. An exhibition of pictures is as essential as a fraternal dinner, and to make this acceptable to all a selection committee was vetoed. Every member might send one picture—no more—and whatever he sent was hung. And there was no line—or rather it was all in one line. The pictures were hung in one straight line around the convention hall; and, if it so happened, the man from the country hamlet, who turns out midgets mostly and has to overwork his lens to deliver a cabinet portrait, found himself sandwiched between two Fifth Avenue leaders.

All paid members got reduced railway rates—and as some

came 400 miles, this was a real consideration. A novel feature of the Convention was an offer of a cash prize of ten guineas for the best hint which would be of benefit to the craft at large. These competitive ideas were enlarged upon in opening by their begetters. One man had a sensible scheme for artificial-light printing; and another pleaded for a method of eliminating against the amateur. A third man, who had tried all depths of devious methods in attracting trade—free prices or free enlargements were among the more innocent of devices—pleaded for high commercial honesty which in his view had led to the haven of good prices. Finally the prize went to a man who prescribed three shillings' worth of sand and cement, plus an equal amount of builder's labour, as the sufficient ingredients towards making an imperishable, unstainable work. Possibly few members will go home and make such a work; but for the chance of the prize all the competitors gave up their ideas free to the meeting.

There is always an interest in the craft as to how the leaders work. Six well-known city men—including Falk, Core, and Hollinger—threw their studios open to members, and demonstrated their methods of work. To those members who wished to study "Old Masters," or the methods of painter artists, a

visit to the Art Museum was arranged, with Messrs. Core and Hollinger as leaders.

Finally, the dinner; a real Bohemian—that is, Hungarian—dinner, in a place where real live artists are supposed to dine and sip beer, and blow clouds of cigarette smoke. The dinner cost six and threepence per head—just half of the total annual dues—and it was paid for out of funds, without any additional levy. If a member wished to do so, he was entitled, on additional payment, to bring one wife or one sweetheart to the feast.

Who attend conventions? The first man I met settled in a tiny village nearly half a century ago. The village has grown, but to-day it numbers less than 3,000 people. His price for a dozen cabinets is twelve and sixpence, and the pictures are well worth the price. Thanks to conventions and educational demonstrations, together with native enthusiasm, he is quite abreast of the times in work; he makes a sufficiency; and he is content. It is very easy to stagnate in a small village; and the small village is the happy camping-place of the travelling photographer who appears from nowhere and floods the country-side with coupons offering a dozen superior and imperishable photographs, guaranteed by the instantaneous process, for three and elevenpence farthing.

### THE PRESIDENT'S ADDRESS.

The following is the address delivered at the opening of the Convention of the P.P.S. of New York by Mr. Pirie Macdonald:

We stand, as an organisation, for two principles paramount to all others—first, the object of this society is the betterment of the business condition of the proprietor photographer, the bettering of the art, as such, being relegated to a place of secondary importance.

We also stand as being self-supporting and independent and opposed to the acceptance of pecuniary assistance, believing that a business organisation should be untrammelled by ties of obligation which would influence or hamper its actions, as well as believing that we should do and have nothing that we cannot fully pay for.

This position was not assumed in arrogance, but as a sane precaution, to preclude the possibility of any interest acquiring an obligation from us which might become embarrassing.

This freedom we consider as essential to our existence, and any curtailment of it has been most vigorously guarded against. This principle is the opposite of that of any other of the professional organisations of the country; as a rule, they look for a large part of their financial support and entertainment from the hands of the interests which supply their materials.

It must be obvious that it has required careful management and a great amount of labour on the part of the Executive Committee to bring about a result, without the help of the manufacturer, which would in any way compare with the associations which have been virtually supported by them. But the result, which we will discuss later, we feel is sufficient to cause you much gratification—and fully repay us for the labour. The matter of correspondence from the president's office alone has involved some 1,192 dictated letters, aside from the preparation, printing, and addressing of some 2,078 circulars and other printed documents; but we have this collection of pictures, involving some 200 persons—more individuals are represented than is usual at a meeting of a National society. We have this magnificent meeting-place, the like of which it has never been the privilege of a society of photographers to use, and one of the few rooms even in this great city where the requirements of the resolution, which authorised the gathering of the exhibit could be carried out, as we were directed to hang the pictures in one line—no picture above or below any other.

We have a paid membership of over 200 at this moment, and are now paying their first dues now.

We have in operation a Free Employment Bureau, which has

placed sixty-two workmen in the studios of our members in about six months, and many more who have not had the courtesy to acknowledge the result of our work for them—a fault unfortunately common also to our members.

We have before us, aside from the benefits to be derived by the contact of men from different parts of the country, a series of demonstrations by six artists of the first rank, all of whom

MR. PIRIE MACDONALD, President P.P.S. of New York.

are justly celebrated, and the unique opportunity of being shown the treasures of the great Metropolitan Museum of Art by Messrs. Core and Hollinger, and a dinner where a plate is provided for every member of the society—and all of this is being paid for by ourselves out of the dues. Surely you will be willing to credit the Executive Committee with devotion!

Lastly, I want to speak of the sections, because the sections are the most important item in our scheme of organisation. It is through the sections that this society must get its real power. The continued touch and the intimacy that is bred in the

sections—the monthly contact and the monthly effort to smooth away the vexed conditions, is what is to prove the health-giving factor of our organisation. Other associations have been formed and have seemed to flourish for a while—have met with more or less success for a while—but have finally “petered” out because the lapse of time between meetings was too great to have interest sustained, and each meeting had to be made out of whole cloth; but our sections, meeting monthly, have kept warm the interest; they have each grown larger and stronger, thus helping to hold together the society all through the year.

The sections have been of use, however, not only in increasing the power of the State Society, but more directly in handling local questions, in knitting together through friendship and confidence groups of men all over the State—groups of men who have by the very nature of their competitive relation been antagonistic—they have come to regard each other as friends and to realise that there is a common interest which must be maintained, a friction to be reduced, with the result of more business, more easily done, more pleasantly done, and a new circle of friends.

Difficulties that have been “discussed” by other associations have been solved in some of our sections; matters that required work and persuasion and confidence have been accomplished within this past short year that other societies have only talked over; and these results have been made possible only through this scheme of dividing the State into small independent units, held together by their common interest in the State Society.

No one capable of prophesying the exact result of the formation of sections happened to be a member of the committee who wrote the Constitution, and it is now obvious that there is not adequate provision for communication between the bodies—

there is no completed scheme whereby the work of each may of profit to the other, where the pioneer's work on a question need only be done once.

There is no complete arrangement for the working together to get any one result, or the dividing of a problem into divisions so that each section may work out its given part and so save the necessity for doing it separately four or five times, and, worse than all, there is no provision for an interchanging of such courtesies which would make for that true cordiality which is the corner-stone of our existence.

The Executive Committee have earnestly discussed this problem and will put forward some suggestions and recommendations in their report which I believe should be given most careful and serious consideration on the part of all those who desire the real success of this society.

While there are many of our members who will doubtless feel that we have as yet not accomplished a sufficient amount of definite result, it is my opinion that, all in all, we are in most remarkably prosperous condition, considering the age of the Society; I feel that we are going slowly but surely to prove that our theory of organisation is the only one which can continue to grow, until we have enrolled every photographer within the State of New York in our membership. We should encourage the building of sections in every locality where photographers are close enough together to be in competition, in order that we may reduce to a minimum the instances where men are doing profitless work, in order that we may establish healthy rivalry through competition of workmanship rather than of prices.

Personally, I should feel perfectly satisfied if this meeting accomplishes nothing more than a deep and earnest desire for more complete organisation.

PIRIE MACDONALD.

## PHOTOGRAPHS BY THE NATIONAL PHOTOGRAPHIC RECORD ASSOCIATION.

THE collection of photographs which we have been able, by courtesy of the National Photographic Record Association, to bring together in the “little gallery” set apart at our offices for such purposes, is of a different character from other assemblages which we have offered for exhibition. The members of the N.P.R.A. do not aim at presenting the mood of a photographer in their pictures, and though a number of the 108 prints possess pictorial value, not that, but the plain record of fact is the quality which is desired in the prints made to swell the number already in the British Museum.

The present exhibited photographs are actually those which are to be the next additions to those deposited with the Museum authorities, and particular interest should attach to them from this fact, inasmuch as the character of print and the form of mounting approved by the National Record Association should be of interest to those whose inclinations are in the direction of similar work.

It will be seen that in almost every case a cut-out mount is adopted in order that the photograph when packed with others shall be protected from abrasion. A standard size of mount is also adopted for convenience of assembling the prints in packages, and, although a print of whole-plate size is preferred, several smaller photographs may be placed on one mount. Those prints in the present exhibition which have not a cut-out will receive one before being deposited with the others.

Turning now to the exhibits themselves, those by Sir Benjamin Stone, the President of the Association, include a great variety of subjects about equally divided between buildings of historical interest and ancient customs in their necessarily modern survival. A press gang party (No. 7), which falls in this latter

division, is a very different thing from that body as it was presented to our youthful imaginations by Captain Maryatt. Yet it represents the equipment actually used in Nelson's day. The same town, Fordwich, Kent, which provides it also supplies the ducking stool (No. 13). “The Hornblower” (the modern Wakeman), of Ripon, Yorkshire, is recorded in No. 22, a photograph which well emphasises the usefulness of record photography to the historian and student. No. 30, “The Speaker's Procession, House of Commons,” is one of the large series of photographs which is the result of Sir Benjamin Stone's tireless energy. The volume, “Parliamentary Scenes and Customs,” in which Messrs. Cassell have reproduced a large proportion of them, may be seen upon the table.

Mr. F. R. Armytage records in No. 43 the ancient office of the “Huntsman” in the Shrewsbury School, the “Huntsman” distinguished in the photograph by his red jersey being the senior boy of his year in the school sports and the dictator in athletic matters. The boys are assembled for the start of the “Tuck's Run.” Among his photographs of the picturesque abbeys of Shropshire, Mr. Armytage includes some of the quaint miseries in St. Lawrence, Ludlow, in one of which (No. 56) is represented a landlady who for using unjust measures is being carried off by two devils to be cast into the jaws of Hell. The lady will be seen in an inverted position in the upper photograph with the illiberal measure still in her hand.

Mr. H. W. Fincham contributes a number of photographs of bygone Clerkenwell, including the copy of an hotel bill of 1853 for refreshments for the churchwardens and others on the occasion of beating the boundaries, the sum of £13 17s. 10d. being expended on the entertainment of the party.

Mrs. Catherine Weed Ward contributes photographs of a series of fonts at Canterbury, Porlock, Lynton, and Warwick, and of a most picturesque ancient stocks at Lynton, Devon. Further photographs of the Yorkshire Abbeys, Rievaulx and Fountains, are sent by Mr. Godfrey Bingley. Lastly, Mr. George Hamell, honorary secretary of the N.P.R.A., continues his

photographs of Essex churches, including that of South Olkendon (No. 108), one of the six round-towered churches in Essex, and of Laindon Church (No. 102), showing the timber framing for supporting the tower utilised as an organ loft.

The exhibition is open to the public from 10.30 to 4.30, Saturdays 10.30 to 12.30.

## TRIAMIDOBENZOLE AND TRIAMIDOTOLUOL AS DEVELOPERS.

[A communication from the laboratory of the works of Meister, Lucius and Brünig to "Photographische Korrespondenz."]

TRIAMIDOBENZOLE and triamidotoluol, whose salts correspond to the formulae—

respectively, have long been known as easily obtainable bodies through the decomposition of the azo dyes of m-phenylenediamine and m-toluenediamine. These compounds were prepared by us for other purposes in a perfectly pure state, and it appeared to be a good opportunity to test them as regards developing powers, which hitherto do not appear to have been investigated. The above constitutional formulae show that there are two amino groups in the "para" and two in the "ortho" position. It might certainly be expected, therefore, that these compounds would show some developing properties. Experiment proved the truth of our expectations. The hydrochlorides of the said diamines develop with sulphite alone, without the addition of alkali, and are considerably more energetic than triamidotoluol and triamidobenzole, and come very near amidol in developing power.

The energetic action of triamidotoluol is all the more striking, amidol, the hydrochloride of diamidophenol, contains only one molecule of hydrochloride, whilst triamidophenol contains three molecules.<sup>1</sup> Sodium bisulphite added to an aqueous solution of the salt in sulphite acts as a much more powerful reagent than with amidol. In order to obtain a good energetic developer this fact should be kept in mind, and a developer made from:—

Triamidotoluol hydrochloride .....	5 gms.
Anhydrous sodium sulphite .....	30 gms.
Water .....	1,000 ccs.

only four to five parts of sulphite are required for one part of amidol. With equal duration of development, triamidotoluol gives the same amount of detail in the shadows as amidol, but the density in the high-lights is somewhat less. Triamidobenzole gives much weaker images.

Whilst diamidophenol or amidol and diamidoresorcine, the two developing agents which have hitherto been used without alkali, will not stand any marked addition of alkali without giving fog, the above-mentioned triamines act energetically and without fog in an alkaline solution, e.g., in a developer composed of:—

Hydrochloride salt .....	5 gms.
Sodium sulphite .....	30 gms.
Potassium carbonate .....	20 gms.
Water .....	1,000 ccs.

The neutral solutions keep for a long time, and scarcely change when on standing for some hours in an open dish. The alkaline solutions, on the other hand, soon turn yellow.

As triamidotoluol has no special advantages over amidol,

either with respect to price or action, its introduction as a new developer does not appear worth while.

The energetic action of triamidotoluol over the corresponding benzole derivative caused us to try whether the higher homologues of developing agents other than benzole derivatives showed similar increased rapidity.

The homologues of p-amidophenol and amidol have often been mentioned in technical literature,<sup>2</sup> and have been patented, though the patents have now lapsed. Nothing appears, however, to have been published as regards the developing powers of these substances as compared with the lower homologues.

We compared first p-phenylenediamine and p-toluenediamine. The formula used was:—

Diamine hydrochloride .....	10 gms.
Sodium sulphite .....	40 gms.
Potassium carbonate .....	40 gms.
Water .....	1,000 ccs.

P-toluenediamine gave a vigorous image quickly; p-phenylenediamine gave only a very faint image after long action. P-xylenediamine developed much more energetically than p-toluenediamine; the former has the formula—

We further determined that the two p-amidocresols develop more energetically than p-amidophenol. The difference is very marked with alkaline carbonate solutions (the phenolates were not tested); it is especially striking, however, in solutions free from alkali. The formula used was:—

Hydrochloride salt .....	5 gms.
Sodium sulphite .....	25 gms.
Water .....	1,000 ccs.

which was tested on transparency plates and gaslight papers. The p-amidophenol gave in five minutes only an extremely faint brownish image; p-amido-m-cresol—

gave in the same time a much stronger image, p-amido-o-cresol—

gave in two minutes a very vigorous black image, so that the latter substance seems very suitable as a developer in neutral solution for gaslight and transparency plates.

Finally we tested p-amido-xenol—

This developed extremely quickly, but produced after a few minutes a brilliant metallic fog.

We would lay stress on the fact that the substances used by us were absolutely pure, and that a contamination, caused in the preparation of the same, by diamido-oxi-compounds was not possible.

<sup>1</sup> Hydrochloride of triamidotoluol is acid to Congo red paper, whilst amidol not.

<sup>2</sup> Hauff, "Eder's Jahrbuch," 1893, p. 245; Andresen, loc. cit., p. 420.

It is thus shown that the introduction of  $\text{CH}_3$  into the benzole ring of the developing substance considerably increases the rapidity of the same.

In order to test the amidol series for similar behaviour we prepared diamido-ortho- and meta-cresol. Whilst diamido-m-cresol—

—showed no noteworthy difference in action to amidol, the diamido-o-cresol—

—considerably surpassed amidol; the image appeared much quicker than with amidol, and was much more vigorous in the same time; there was no fog.

The same regularity is again seen with the triamido-diamidol and p-amido-oxi-derivatives, and we must add to the existing laws of developing powers the following:—

The developing power of a benzole derivative, which contains at least the two atomic groups necessary for developing, is increased by the introduction of a  $\text{CH}_3$  group in the aromatic ring. The action of a  $\text{CH}_3$  group is especially strong when it appears in the ortho position to an hydroxyl group.

E. KÖNIG.  
O. STAHLIN.

## NEW YELLOW GLASS SCREENS.

For many years it has been recognised that the ordinary yellow glass filters or screens have been unsatisfactory, because, besides yellow, they contained a considerable amount of black or neutral tint, the only effect of which was to prolong the exposure. This was inevitable, because the black, not acting selectively but generally on the whole of the spectrum, simply reduced the intensity of the yellow, orange, and red as much as it did the blue. Further than that, the yellow of the glass, whilst reducing the intensity of the blue and blue-violet, transmitted the ultra-violet, the very region which, invisible to our eyes, should not be allowed to act on the plate.

This black, according to Eder, was unavoidable, and due to the fact that the molten glass was stirred with a stick of wood, which

have practically had no yellow dye, which was completely opaque to the ultra-violet, except in rather dense colouring.

For many years the well-known glass works of Schott and Genossen of Jena, have been trying to make a yellow glass which should answer all theoretical requirements, and according to Dr. Zschokke, in the current number of the "Photographische Mitteilungen," this has been finally accomplished by Dr. Zschimmer, of the above-named Jena firm.

Some screens of the new glass, worked by C. P. Goerz, have been tested by Dr. Zschokke against the old screens in a diffraction spectrograph, giving equal exposures to each. The results are shown in Fig. 1, the old glasses being marked "K" and the new, "Sch."

From this illustration it will be seen that the plate used gives the whole of the spectrum, from the ultra-violet about  $\lambda$  3,000 to the D lines  $\lambda$  5,903, with two maxima of sensitiveness, the first in the ultramarine blue  $\lambda$  450, and the second in the yellow  $\lambda$  550 approximately. The ultra-violet is absorbed by the "bright K"

Fig. 1.

not only imparted the colour, but was also partially charred, and caused the suspension of minute particles of charcoal in the flux. Glass with a flashed surface of a silver salt would give a yellow of the necessary brilliancy, but it was impossible to make this coloured in the mass, because the silver separated out as an opaque salt and caused cloudiness.

Failing a perfect glass, we have been obliged to be content with what was obtainable, or have had to use stained gelatine films, which, on account of their sensitiveness to moisture, etc., have never been satisfactory. Moreover, until the introduction of filter yellow K, we

Sch dark K dark Sch medium K medium Sch bright K bright Without filter

Fig. 2.

filter. The spectrum begins at the H line, about  $\lambda$  4,000, and reaches to D. "Sch bright" absorbs approximately the same in the ultra-violet as "K bright," but is so transparent for green and yellow light that from the F line, about  $\lambda$  5,000, scarcely any difference is to be detected between the screened and the unscreened spectra. "Medium K" absorbs to about the G line,  $\lambda$  4,300, does not shorten the other end, but shows distinctly a darkening in the yellow and green, as compared with "bright K." "Medium Sch" absorbs to about the F line,  $\lambda$  4,700, but is practically completely transparent for the D line.

The advance is seen most plainly when comparing "dark K" and "dark Sch." The former absorbs completely only to the F line, but darkens it in such a manner that only the maximum in yellow is visible. "Dark Sch," on the other hand, absorbs beyond the F line to about  $\lambda$  5,000, and remains so transparent from the b line

33, and between the screened and unscreened spectra no differences to be seen.

was determined by experiment that "dark K" required four times the exposure to give the same density in the yellow as obtained with "dark Sch."

2 shows the action of the new filters with an outdoor subject. In too, the whole of the exposures were equal, and the differences were very marked. In order to obtain approximately equal density and without the different filters—absolutely equal densities are obtainable on account of the differences of gradation—the following exposures are required:—

Bright K" .....	3	"Bright Sch" .....	2-3
Medium K" .....	9	"Medium Sch" .....	5
Dark K" .....	18	"Dark Sch" .....	6

advance of these new filters over the old lies in the reduction of exposure to one-third without loss of correctness of tonal

firm of C. P. Goerz is placing these new filters on the market in three tints, which require 2, 4, and 6 times the exposure with the same colour-sensitiveness as those used in the above experiment. With normal density of the maximum in the yellow the greens absorb the spectrum to about the H. S and F lines respectively.

#### THE EASTMAN KODAK COMPANY.

Report of the Eastman Kodak Company, of New Jersey, for 1906 balance sheet as at December 31 last have just been issued. The results of the year eclipse the previous records of the company, although they have been. The net profits, after making provision for depreciation on buildings, plant, and machinery, and after setting aside a sum of £103,092 to create a special fund for the replacement of plant, amount to £1,013,546, as against £827,610 for the previous twelve months—an increase of £185,936. Reckoning £103,092 taken out of net profits, the increase is £289,028. Dividends of 6 per cent. upon the preferred capital and 17½ per cent. upon the common have been distributed—leaving £232,473 added to the undivided Surplus Fund, increasing it thereby to £702. In addition to this surplus there are now special reserves amounting to £276,702.

The financial position of the company appears to be exceedingly strong, its liabilities being only its current trade accounts, amounting to £50,965, while its current assets, excluding the value of its buildings and plant, figure at £2,499,685. Of this latter no less than £1,271,023 consists of marketable bonds and cash on hand.

The earning power of the company shows a steady increase, as will be seen from the following official statement of annual earnings:—

Year ending December 31, 1895 .....	£ 49,656
" " " " 1896 .....	122,676
" " " " 1897 .....	185,232
" " " " 1898 .....	243,232
" " " " 1899 .....	355,919
" " " " 1900 .....	465,816
" " " " 1901 .....	517,347
" " " " 1902 .....	564,455
" " " " 1903 .....	606,740
" " " " 1904 .....	688,484
" " " " 1905 .....	827,610
" " " " 1906 .....	1,116,638

The earnings for last year after paying 6 per cent. upon the preferred capital, are equal to over 25 per cent. upon the Ordinary shares. The shares at the present market prices of \$115 for the preferred and \$270 for the Common, yield 5½ per cent. and 7½ per cent. respectively.

#### INTERNATIONAL PHOTOGRAPHIC EXHIBITION AT DRESDEN, 1909

MEETING was held at Dresden, under the presidency of Geheimrat Dr. Mieth, to discuss, in company with delegates from different parts of Germany, arrangements for the forthcoming international photographic exhibition, to be held in Dresden in 1909. Among others present were Professor Mieth, Berlin; Dr. Schultz-Henke, Berlin; Dr. Seeliger, Leipzig; Herr Matthias-Masuren, Halle; and Herr von Rohr, Jena. Herr Beutler announced that the municipal authorities in Dresden had expressed the greatest interest in the exhibition, and were prepared to support it by every means in their

power, presuming, of course, that the exhibition received sufficient support, and that it was sufficiently financed. Herr Springer, of our contemporary "Der Photographische Industrie," then gave a review of the proposed programme. The exhibition, he said, was to be planned in the widest possible way. Hitherto similar exhibitions had been somewhat limited in their scope, but it was the desire of the promoters to represent photography in all its branches, as it had progressed in all civilised countries. Apart from demonstrating the present industrial, commercial, and scientific aspects of photography, it was desirable to include in the exhibition sections which should show the historical and documentary applications of photography, in addition to illustrating the history of photography itself. Professor Kübler suggested that meteorology, telegraphy, photography by electrical connection, and photometry might figure in the programme. Professor Mieth expressed the opinion that the programme as presented was exceedingly well drawn up and comprehensive, and he suggested that it might be passed in its entirety. Dr. Schultz-Henke advised that the more important German photographic societies should be allowed to appoint a representative upon the organising committee of the exhibition. Professor Oscar Seyffert, of Dresden, was elected chairman of the exhibition committee, and Herr Consul-General Klempner, treasurer.

#### THE BALLADE OF THE GUMMIST.

From "The American Amateur Photographer."

A pallid face and a fishy eye;  
A mien betokening deep despair;  
Clothing corroded with alkali  
And frescoed over with pigments fair;  
Chunks of the same in his tousled hair—  
"Some kalsominer a prey to rum!"  
You say? Ah, no, you're in error there;  
He is the fellow that works in gum!  
His conversation, should you stand by,  
Is "broad and sketchy," and somewhat bare;  
Ideas suppressed do but signify  
Details suppressed in the "studies" rare  
Evolved by him—but his weighty air  
As he speaks strikes all who hear him dumb;  
Dispute, Rash Listener, if you dare!  
He is the fellow that works in gum.

*Sed loquitur*—"If you multiply  
The colloid factor you must beware!

If you use Lalanne you must rectify.  
With a badger blender, the faults that e'er  
Obtrude themselves, for despite your care  
Mucilaginous striae are wont to come,  
And these will the notes of tones impair."  
(He is the fellow that works in gum!)  
But we, impotent, can only stare,  
And wonder whether his prints are bum,  
Or fruits of Genius beyond compare;  
While we mentally vow to refrain from gum.

#### DEATH OF THE REV. T. PERKINS, M.A.

A WELL known worker and writer in the photographic world has passed away in the person of the Rev. T. Perkins, M.A., rector of Turnworth, Dorset, at the age of 65. After a distinguished academic career at Blundell's School, Tiverton and Christ College, Cambridge, Mr. Perkins was admitted to Holy Orders in 1869, and after filling the post of assistant master at the Grammar Schools of Durham and Reading was appointed head master of Shaftesbury Grammar School in 1878. Fifteen years later he accepted the living of Turnworth, where he remained till his death, on March 21 last. Although an enthusiast on photographic matters in general, a regular attendant at the Convention, Mr. Perkins devoted himself chiefly to the study of architecture, both domestic and ecclesiastical, but specially the latter, and his writings on the subject, such as "A Handbook of Gothic Architecture," and several handbooks on cathedrals and churches in "Bell's Cathedral Series," show that his knowledge of his subject was both intimate and thorough. His latest work, a treatise on "Romsey Abbey," completed shortly before his death, will be read with interest at the present time. Archaeology also obtained a share of Mr. Perkins' attention, and a book, entitled "Memorials of Old Dorset," which he was editing and partly writing, was left unfinished at the time of his death.

## Exhibitions.

### WALSALL PHOTOGRAPHIC SOCIETY.

The annual exhibition of this society, which was held in the Assembly Rooms, Walsall, from April 11 to 13, may be described as a huge success, both as regards the number of exhibits and the quality of the work sent in, the latter being of a more artistic character and showing greater individuality than in previous years. The exhibition was opened on Thursday, April 11, by Mr. E. J. Shaw, J.P., Mr. T. Partridge acting as chairman in the unavoidable absence of the president, Alderman Walter Hughes. Mrs. G. A. Barton and Mr. Walter J. Morgan, R.B.A., judged the exhibits, and awarded the two special prizes—namely, Mrs. Barton's, for the most original figure study, and the president's, for the best picture in the exhibition—to "The Bride of Lammermoor," by W. Meikle, the award being so popular that the winner was "chaired" by his fellow exhibitors when announced. In the other classes the awards were as follows:—Landscape: 1st, "The Day was Gently Drawing to a Close," by D. S. Johnson; 2nd, "A Bit of the Black Country," by W. T. Comer (hon. sec.). Hon. mention, "Nafford Mill," by W. A. Hubball; "Sand Dunes," by W. H. Bullock; "A June Morning," by G. W. Richmond; "A Black Country Moor," by Ed. Holmes. Seascape: 1st, "Seafog," by W. T. Comer (hon. sec.); 2nd, "Drifting with the Evening Tide," by W. A. Hubball. Hon. mention, "The Quayside, Teignmouth," by B. J. Dexter; "Sunset Off the Conway," by A. Ford. Genre and Figure Study: 1st, "Sister," by Geo. W. Richmond; 2nd, "Ruth," by Mrs. Dore Leckie. Hon. mention, "The Hon. Sec.," by Mrs. W. T. Comer. Architecture: 1st, "North Ambulatory, Norwich Cathedral," by W. A. Hubball; 2nd, "South Choir Aisle, Tewkesbury," by W. H. Bullock. Hon. mention, "The Abbey Passage," by Ed. Holmes. Flowers and Still Life: "Apple Blossom," by B. J. Dexter. Novices: 1st, "The Smithy," by W. A. Dunham; 2nd, "Early Morn," by Wm. Moreton. Hon. mention, "Silver Birches," by W. R. Bowen. Lantern Slides: 1st, Mrs. W. Bullock; 2nd, Mr. A. Ford. Hon. mention, Mr. W. Meikle.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents were made between April 2 and April 7:—

**PLATES.**—No. 7,885. Improvements relating to photographic plates or films. Philip Arthur Newton, 5, Bream's Buildings, Chancery Lane, London, for Lumen. Ges. mit beschränkter Haftung, Germany.

**PRINTING APPARATUS.**—No. 8,075. Improvements in photographic printing apparatus. Thomas Thomassen Sabroe, 65, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**COLOUR PROJECTION.**—No. 3,766. 1906. The invention consists of a method of three-colour projection, in which a separate projecting lens is used for each colour record, and the images thus formed on the screen superimposed by means of a form of reflecting prism or prisms  $a$   $a^1$ , having faces arranged at such angle or angles as may be necessary to cause the light rays to converge to any desired point. The type of prism is therefore such as to give two internal reflections, and is designed so that the faces of the prism at which the beam enters and emerges are normal to such entering and emerging beam. The invention consists in so modifying the prisms of the Fresnel type above referred to as to cause the rays which enter parallel to the axis of the lens,  $b$ ,  $b^1$ ,  $b^2$ , to emerge, making an angle with that axis, and so make it possible to correctly superpose the images. The

prism or prisms may be mounted in suitable holders or can be adapted for adjustment in a vertical and horizontal plane—the prism or prisms may be adapted for universal movement. By these means the prisms may be adjusted so as to permit superimposing of the images to be effected with accuracy. In projecting three-colour records with three projecting lenses image is preferably projected direct on to the screen with the intervention of a prism, and the other two images caused to register with the first by means of prisms arranged in front of the other two lenses.

Fig. 1.

The prism may be conveniently arranged with respect to lenses, and to the positives or records  $a$ . The colour screen  $c$ ,  $c^1$ ,  $c^2$  may be placed before or behind the positives, before or behind the lens, before or behind the prisms; or the prisms may themselves be of a suitable colour.

The angles of the faces pertaining to the prisms will vary according to requirements and to the distance of the screen from the lenses, the degree of convergence necessary, but by means of the present invention a correct projection and superimposing of the images

Fig. 2.

is ensured; the colours being truly registered and blurring effect entirely obviated.

It will thus be seen that the employment of reflecting prisms in the projection of a coloured subject in the manner herebefore described enables a superimposing of the two colour pictures to be obtained upon the centre or inner picture.

It will be further understood that in obtaining the negative prisms are not employed, but the negatives are taken by means of three lenses, mounted as closely as possible, so as to reduce stereoscopic effects, and that three-colour screens are disposed between the subject and the film, the three negatives being

taken simultaneously on the film. Benjamin Jumeaux, Southwick, near Brighton.

**COMBINED PHOTOGRAPH FRAME AND CINEMATOGRAPH.**—No. 12,806. 1906. The invention consists in the combination with a frame for holding a photograph of means for producing an animated picture, the object of the invention being to exhibit the portrait of a person or of any other subject, and at the same time an animated portrait either of the person or subject, or of a scene having some relation with person or subject. The four claims require the six figures for the proper explanation of the details of the mechanism. Henri Louis Huet, 114, rue du Temple, Paris.

**WASHING MACHINE FOR BLUE PRINTS.**—No. 12,806. 1906. The invention consists of an apparatus in which the paper is moved upward so as to present one surface to the action of falling water, the water running off quickly and thus never becoming saturated. The action of the apparatus is as follows:—

The sheet of paper 2 is led over transverse rods 3, arranged in a curve over a trough 4, adapted to receive the washing water and arranged so as to maintain the level of the water in the trough at such a height that the sheet 2 will not at any time come in contact with the water, thus keeping the back or rear side of the sheet dry. A guide rod 5 is arranged over the rods 3, and the paper passes between the rods 3 and 5. After passing over the rods 3, the paper is led upwardly over transverse rods 6, arranged on an incline at the back of which is arranged a guard plate 7. The angle of inclination of the rods 6 and the

Fig. 1.

Fig. 2.

guard plate 7 is quite steep, so as to allow the falling water a quick descent and thus prevent the same from saturating the sheet of paper, but acting merely to wash the same as the paper is carried upward. The paper is passed over the front of the lower roller 9, and in back of the upper roller and a spraying device 8, arranged so that the water will be sprayed directly on the sheet of paper and thus running or falling over the outer surface of the same downwards, until it flows off each side of the sheet into the trough 4. The paper, after being led back of the upper roller 9, is passed between two wringing rolls 10, which squeeze the water from the paper so as to reduce the paper from a wet to a moist condition. In Fig. 2 is shown a flat rubber strip 10a, supported in a split tube 10b, so as to bear on the wet surface of the paper, and wipe the surplus water and moisture therefrom. The sheet of paper is led horizontally across and about a roller 11, with which it is held in contact by an endless tape 12, passing over an upper roller 13, and about oppositely disposed rollers 14. The paper is thus carried around by the tape on its outer surface downwards, across and upwards, to a delivering roller 15, mounted opposite the roller 11. Both the rollers 11 and 15 are set slightly inwardly, so as to firmly

engage with the tape 12 and thus keep the sheet of paper taut. Charles Francis Pease, 182, Dearborn Street, Chicago, Ill., U.S.A.

## New Trade Names.

**PRESTO.**—No. 290,186. Photographic paper. Otto Scholzig, 31, Binfield Road, London, S.W., manufacturer. February 6, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Dexterity in Manipulation.

Writing on the above subject in "The Photographic News," Mr. C. H. Hewitt says: "As to the method of applying the developing solution, it may first of all be said—Don't wet the plate in clean water prior to development. Don't pour the developer into the dish and then drop the plate into it. Don't slop the solution over the plate in any indiscriminate way. If the developer starts at one edge of the plate and proceeds across its surface in an even wave, there is not likely to be an uneven mark or a single air-bell. On the other hand, if the developer starts in the middle, flows to one edge, and then by a re-tilting of the dish is made to flow back, a row of air bells is most likely to be formed when the return wave leaves the wetted surface of the film and passes to the dry surface."

### Backgrounds for Flower Photography.

The best backgrounds (says Mr. H. Edwardes, writing in "Photography") are white and grey papers, which can be got in large sheets from dealers in artists' materials. A very dark background is useful at times, though its general tendency is to make lightly coloured flowers look too startling. A piece of black velvet does as well for this purpose as anything, but it must be kept free from creases. If there are any folds likely to show they can be hidden by hanging the board carrying the velvet and letting it swing slightly during exposure, keeping the folds as nearly as possible vertical. Or it may even be shaken during exposure, though this usually results in shaking the flowers. Generally speaking, the grey background is the easiest to use; both plain black and plain white are readily misused.

### Carrying the Camera on a Cycle.

Nearly every modern cycle (says Mr. Percy F. Westerman, in "Focus") has a "forward lug" handle bar, thus allowing a bag to be fastened to it without risk of damage from the head of the brake. To make doubly sure, however, I have had a leather carrying case constructed as follows: The case is provided with straps for carrying across the shoulder, the back of the case—i.e., the part that comes next to the handle bars—is made of double thickness, with a piece of light strong oak wood placed between them. This forms a firm base for the changing bag and its contents to rest against, whilst the camera is placed between the changing bag and the front of the carrier, which in its turn is secured to the handle bars merely by taking a turn round the bars by means of the long straps, and fastening the latter over the front of the leather carrier.

## New Books.

"THE PHOTO-MINIATURE."—Our concise and always informative contemporary has evidently benefited by its recent rest. Though scarce a month ago that its "Focal-Plane" number reached us, No. 78 is to hand, containing a series of contributions on "Printing Papers, Described and Compared." The number conveys a good idea of much needed information on the relative virtues of printing papers, as regards range of gradation. Messrs. Dawbarn and Ward issue "The Photo-Miniature" in this country at 6d.

## New Apparatus, &c.

Thornton-Pickard Nimrod "Automan" Hand-cameras. Made by the Thornton-Pickard Manufacturing Co., Ltd., Altrincham, Cheshire.

We have recently had the opportunity of examining four models of these hand-stand Nimrod "Automan" cameras, manufactured by

"Nimrod" Automan No. 2.

the Thornton-Pickard Company. All have one common feature—namely, the very neat "walk-out" movement by which the camera front moves automatically into the position of infinity focus on the

"Nimrod" Automan Camera, Nos. 2 and 3 Models.

baseboard being pulled down. In other words, the act of "opening" the camera sets it ready for work.

The cameras are sold at prices from 42s. to 84s., No. 1 of the

"Nimrod" Automan No. 4 showing universal swinging back (forward swing).

series (42s.) being of single extension. The others, however, are of double extension, and No. 4 (84s.), in addition to the usual features, has a universal swinging movement of the back which provides for

all conditions of verticality and gives a little additional extension. This last camera is fitted with the Thornton-Pickard "Panoptic" shutter and Beck lens, the others having "Gem" between-lens shutter and R.R. lens.

At the very moderate prices at which they are issued, the cameras should have a great vogue among beginners in photography, and dealers in particular would do well to make themselves acquainted with the series, for the utility of the "walk-out" movement—and we are not minimising it in the least—should be felt by the dealer when selling the camera as by the user in the practice of his hobby.

The "Merito" Developing Tank. Made by W. L. Parkinson, Ltd., 5, Commutation Row, Liverpool.

In adopting the principle of the dipper of the old wet-plate days in providing a tank for vertical development, Messrs. Parkinson have undoubtedly consulted the convenience of those employing this method of development, one, we find, which is steadily gaining favour. The tank, which in the quarter-plate size, measures  $3\frac{1}{2}$  by 4 inches, is provided with twelve carriers, each holding one negative, fitted across the upper part with a rod which rests in a groove on the sides

of the tank. Hence the plates in their holders are held free to swing through a small angle, and the user is therefore able to impart a gentle motion to the developer. The apparatus, in japanned metal, with light-tight cover and twelve carriers, costs 5s., and is a welcome adjunct to the practice of development by the tank method.

CELLULOID MEASURES.—Messrs. Marion and Co., 22-23, Soho Square, London, W., have just issued a series of celluloid measures, which, while being beautifully light and unbreakable, have the

additional advantage of graduation in both British and metric units. It should be a convenience to the worker to be able to measure ounces or ecs. at will, and the graduates will serve to familiarise

user with the metric system. The measures are supplied in 1, 4 oz., and 10 oz. sizes, at 7d., 10d., and 1s. 10d. respectively.

MESSRS. R. AND J. BECK, LTD., 68, Cornhill, London, E.C., send one of the new lens-testing charts bought out by them at the rate, post free, of 2s. 6d. The chart consists of a border of interlaced, horizontal, and vertical bars, and is a conveniently severe test of astigmatic aberration in the lens. The whole space is taken up by a block type printing of various degrees of boldness, and therefore the flatness of field. The chart includes a six-inch line, which

is used to determine the equivalent focal length of the lens. The line is used to give an image of 1 inch in length, and the space from diaphragm to screen is measured. The latter, divided by seven, gives the focal length from the formula  $f = \frac{F}{r+1}$  where F is the conjugate and r the scale of reduction.

## New Materials.

Page-Croft Tinted Self-toning Papers. Made by the Page-Croft Paper Company, Cooksey Road, Birmingham.

Page-Croft's firm has placed upon the market a series of self-toning papers, which, unless we are mistaken, are an entire novelty in particular line of printing papers, and afford results which would be very satisfactory to a wide class of photographers, both amateur and professional. The papers have a matt surface, akin to that of smooth canvas, and are supplied in the following colours: pale green, pale terra-cotta, pale blue, and grey. The tone obtainable on the papers varies with the strength of the fixing bath, and our own trials with one of three ounces to the pint gave us a reasonable brown tone, which on its tinted support gains immensely in effect. The character of the prints is extremely rich, and it is an exaggeration to say that the effects as closely resemble carbon as any of any printing-out papers we have handled; indeed, from a view of suitable vigour, the prints might be mistaken for good ones. We feel sure that a trial of the papers will repay any photographer who is anxious to obtain a variety of effects, and in the simplest possible way.

## CATALOGUES AND TRADE NOTICES.

CATALOGUE of Jas. A. Sinclair, Ltd., 54, Haymarket, London, is one which we would specially signalise as one to be obtained and studied, not chiefly for the number of articles which preface the catalogue proper, but for the very discreet selection evidenced in the apparatus which is illustrated and priced. Mr. Sinclair, than whom no one is better qualified to pronounce on the reliability of apparatus for amateur photography, will have none of the cheap and shoddy, and those anxious to purchase any appliance for satisfactory work, cannot do better than let him guide them in the expenditure of his money. The articles which, to the length of 16 pages, the firm gives to purchasers of its catalogue, include "The

Camera at Home," by E. T. Holding; "Intensifying and Reducing," by J. McIntosh; "Bromide Printing and Developing," by J. Sterry; "Gum-bichromate," by J. C. S. Mummery; "Carbon Printing," by H. W. Bennett; "Law for Photographers," by E. B. V. Christian; and, lastly, "Hand Cameras: Their Selection and Use," by Jas. A. Sinclair. The last-named contribution, full enough to be a safe guide and brief enough to be quickly assimilated, is as effective a means of deciding which hand camera to purchase as any we can recommend. In hand cameras, as in other matters, we could recommend those in need of advice to no one better qualified than Mr. Sinclair, whose policy of specialising in the supply of a really satisfactory article deserves every commendation.

MESSRS. THOMAS ILLINGWORTH & Co., LTD., of Willesden Junction, London, N.W., have issued a little booklet, entitled "A Free Guide to Photographic Printing," which contains much useful information in a comparatively small space. In addition to instructions for printing in various processes, the causes of many of the difficulties most frequently met with, and their remedies, are dealt with in a clear and concise manner, and the booklet should prove extremely useful to those engaged in photographic work, whether amateur or professional. Messrs. Illingworth state that they will be pleased to send a copy of this "Guide," which also contains their price list, to all applicants, and also to supply copies to dealers for distribution.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, APRIL 19.

West London Photographic Society, "Photo-Micrography." J. R. and G. R. Lynch.  
Sutton Photographic Club. Photography Prize Slides.

SATURDAY, APRIL 20.

Aberdeen Photo Art Club. Outing to Kinaldie.  
North Middlesex Photographic Society. Outing to Monkwood.  
Chelsea and District Photographic Society. Outing to Woolwich.  
Borough Polytechnic Photographic Society. Outing to Wimbledon.  
Hull Photographic Society. Outing to Sheffield. Annual Meeting of the Y.P.U.

MONDAY, APRIL 22.

Catford and Forest Hill Photographic Society. "Figure Studies." E. T. Holding.  
Leeds Photographic Society. "Wells—Its Cathedral and Neighbourhood." A. E. Hasse.  
Gravesend and District Photographic Society. Paper by J. T. Dalladay.  
Kidderminster Photographic Society. "Bird and Animal Photography." W. Weaver Baker.  
Southampton Camera Club. Lantern Slide Competition. Illustrate the following: "Sunshine and Shadow."  
Boswell Park and District Photographic Society. "Wellington S.C.P. Plates and Papers." Demonstrated. A. H. Dunning.

TUESDAY, APRIL 23.

Royal Photographic Society. Technical Meeting. "The Spectroscope, Chemical Metallurgical, Geological, and Astronomical Analysis." E. J. Wall and C. P. Butler.  
Wallington Camera Club. "Bromide Papers and Negatives." The Rotary Company.  
Rotherham Photographic Society. "Flower Photography." H. T. Malby.  
Sheffield Photographic Society. "Holland and the Hollanders." James W. Wright.  
Hackney Photographic Society. Lecture by H. W. Bennett.  
Keighley and District Photographic Association. "Platinotype." J. Skilbeck.  
Hove Camera Club. "Colour Photography." Dr. E. F. Grun.

WEDNESDAY, APRIL 24.

Croydon Camera Club. "New Shutter-Testing Apparatus." A. E. Salt. Lantern Evening.  
Leicester and Leicestershire Photographic Society. Ladies' Night.  
Hampstead Scientific Society. "Principles of Composition." W. E. Tindall, R.B.A.

THURSDAY, APRIL 25.

Bolton Amateur Photographic Society. "Theory and Practice of Self-Toning Papers." John J. Griffin & Sons.  
Handsworth Photographic Society. "Photographic Printing on Fabrics." J. A. Liverpool Amateur Photographic Association. "Etching." Fred. Burridge, R.E.  
London and Provincial Photographic Association. Queries and Answers.  
North London Photographic Society. "Gum Bichromate." Demonstrated. C. Wille.

### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

The usual monthly meeting of the General Committee was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, the 12th inst.

Present: Messrs. A. Ellis, S. H. Fry, Martin Jacolette, H. E.

Hull, A. Mackie, H. J. Mendelssohn, T. Rowe (Eastbourne), E. Scamell, Lang Sims, H. C. Spink (Brighton), and R. Fellowes Willson. Mr. H. C. Spink, president, in the chair. The hon. secretary reported the results of his negotiations with the Fine Art and General Insurance Company, with regard to the special terms to be granted to members of the P.P.A. for insurance under the Workmen's Compensation Act, 1906. He also read the conditions contained in the policy to be issued. It was agreed that they seemed just and reasonable, and further agreed that the hon. solicitor should be asked his opinion on them. After discussing various points connected with the Act, the draft was read of the notice to members in connection with their liability under the Act and the particulars of the insurance scheme for insertion in the forthcoming "Handbook." This was approved and passed for publication.

The hon. secretary read draft of new matter for insertion in the "Handbook," extending the part devoted to information on legal and business matters to five extra pages.

Several letters from members were read and considered, and the hon. secretary was instructed thereon.

Mr. Alexander Mackie was re-elected hon. secretary, and Mr. Lang Sims hon. treasurer for the ensuing year.

#### ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held April 16, Mr. J. C. S. Mummery, president, in the chair. Mr. Arthur Marshall, A.R.I.B.A., delivered a lantern lecture, entitled "Some Dutch Pictures," in the course of which he gave a description of visits paid to Holland, and of a particularly enjoyable cruise on the canals of Friesland. Mr. Marshall illustrated his lecture with a number of excellent lantern slides, the negatives of which have inspired some of his exhibition pictures. His lecture was received with much appreciation by a crowded audience.

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—At Wednesday's meeting of the organising committee the draft rules were finally agreed, and it was decided to hold the first meeting of the society on the evening of Wednesday, April 24. On that occasion the society will act on the principle of the "open door," and amateur photographers, from Kodakers to finished pictorialists, will be cordially welcomed. After the house-warming there will be a lecture by Mr. F. J. Mortimer, on his pet subject, "The Photography of the Sea," illustrated with slides from some of his best seascapes. Over thirty new members were elected by the committee at the same meeting, and candidates are still coming, apparently anxious to be in the original list of members, and to share in the election of the committee and officers on the 24th. The hon. secretary is Mr. John Nixon, of Ingleside Grove, Blackheath, and amongst the vice-presidents is the Mayor of Lewisham.

**LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.**—Meeting held April 11, 1907, Mr. T. E. Freshwater in the chair. Mr. E. R. Human passed round two fine prints upon Mattos linen, which had been toned first with gold and afterwards platinum, a fine blue-black tone being the result.

Mr. E. Human then lectured upon and demonstrated carbon printing, approaching the subject from a beginner's point of view. He said that carbon, from its extreme simplicity and absence of chemicals, should be the very first process tried by the beginner.

Speaking of the safe edge, he recommended that a series of narrow masks should be cut for the various sized plates one used, and that these should be used between the glass of the printing-frame and the negative. By so using them exact contact could be obtained between tissue and negative, which would not be obtained if the masks were used between negative and tissue. His reason for using the masks was the large amount of time and trouble saved as against the usual method of using an opaque colour. If one only required a small part of a negative printing, a special mask was easily and quickly cut. The following he gave as a good sensitising bath:—

Potass bichromate	...	...	...	1/2 oz.
Water	...	...	...	10 oz.

Dissolve, and add three to four drops of liq. ammonia, .880.

For use, pour into a dish of larger size than the paper in use, to

the depth of 1 1/2 to 2 inches, insert tissue, remove any air bubbles, let soak for from 120 to 200 seconds, then, upon removal, lay downward upon a sheet of glass, zinc, or a pulp-board. Squeeze the back with a flat squeegee to remove any excess of solution, hang up to dry in the dark or a non-actinic light. Drying should be complete in four hours.

For printing any meter could be used. He himself preferred the Wynne's or the Akuret, but for beginners he said choose another negative of as nearly as possible the same density as the one to be used, and print a piece of P.O.P. to finished depth, not toning depth, by which time the tissue would be printed.

The reason for transfer was then somewhat fully explained, following being given as a formula for waxing the temporary support in the double transfer process:—

Yellow resin	...	...	...	36 grains
Yellow wax	...	...	...	12 grains
Ether	...	...	...	2 oz.

Melt the wax, add the resin, stir well, and add the ether. The mixture should be applied by pouring a small pool in the centre of the paper, and rubbing it evenly all over by the aid of a tuft of cotton wool.

Mr. Human then proceeded to demonstrate the development of prints by developing some ten to twelve half-plate prints on various colour tissues, every one of which turned out a success.

Mr. Smith asked if it was possible to finish the prints with a glossy surface. Mr. Human replied that all that was required to coat a sheet of clean glass with enamel collodion, patent plate glass being perhaps the best, and use the double transfer, when the print would retain a very high gloss.

Messrs. Rapson, Teape, and Hart also took part in the discussion. A vote of thanks, proposed from the chair, closing the proceedings.

## Commercial & Legal Intelligence

**HARD LABOUR FOR A CANVASSER.**—Albert Evans, 29, canvasser, pleaded guilty, at the Devon Sessions last week, to obtaining small sums by false pretences from Mary Ann Newcombe, at North Devon, and Louisa Balch and Alice E. Hartnoll, at Westleigh, in February last. Mr. Percival Clarke, prosecuting, said these cases were a sample of those which might have been brought against a prisoner. At the last Quarter Sessions he was sentenced to a month's hard labour for a similar offence. His case enlisted the sympathy of Mr. A. Mills, photographer, of Exeter, who got into communication with the prisoner through the chaplain of the gaol in view of that honest employment might be found for him when he came out of prison. Mr. Mills engaged him to canvass for photography on commission, but subsequently, owing to unsatisfactory results which he received, prosecutor cancelled the engagement, but afterwards found that he had continued to receive moneys on account of orders purported to have been taken on behalf of Mr. Mills. Prisoner, in a written statement, attributed his gradual downfall to bad company and drink. He had had an excellent education, it was his intention to avail himself of an opportunity to leave the country and make a fresh start after his present sentence was completed. The Court sentenced him to six months' hard labour.

**A CANVASSING CHARGE WITHDRAWN.**—George Samuel Webber, fine-art dealer, of 34, Portland Road, Hove, Brighton, surrendered to his bail, at West London, last week, to answer the remaining charge of obtaining money by false pretences.

Mr. Sefton Cohen, who appeared for the Director of Public Prosecutions, asked leave to withdraw the prosecution on the ground that there was no reason for supposing that the defendant carried on a fraudulent business. The accused, continued Mr. Cohen, traded under the name of the International Fine Art Company, of 112, Uxbridge Road, Shepherd's Bush, and at other addresses. He employed lecturers to solicit orders for the enlargement of cabinet and other photographs on the terms that no charge was to be made for enlargement so long as a customer agreed to purchase a frame for

ged photograph. Several complaints reached the police, and result three ladies came to the court and swore an information, which a warrant was issued for the arrest of the accused. A and was granted when the case came before the magistrate, and Director of Public Prosecutions thoroughly investigated the case. quires were made by Detective-Inspector Pollard and Detective-ant Burrell, and it was ascertained that an actual business was y carried on, that a staff was employed, that the rent of the ouses was paid, and the books showed that orders had been uted. In fact, all the ingredients which one would expect to find fraudulent business were absent. As regards the nature of the essage, the Director of Public Prosecutions wished it to be under- at that the withdrawal of the prosecution must not be taken to at that the methods followed by the defendant met with his oval; and, in view of the number of complaints made to the e, he suggested that this was eminently a case for investigation. H. Curtis Bennett, who appeared for the accused, hoped that ame publicity would be given to the withdrawal of the charge as extended to the arrest of the accused. Great damage had done to the defendant personally and to his business by this ution, and he (Mr. Bennett) could not but think that the ant would never have been granted if two of the ladies who e the information had not made a serious omission from the mation. It was the defendant's practice to go from one place uther—both in London and the country—so as to exhaust all possibilities of his business, and it was very unfortunate that that mate method of business had been used against him as tending pport the allegation of the police that he "had committed ar frauds all over the country." Mr. Bennett concluded by ing out that the accused suffered eight days' incarceration under and at Brixton Prison.

Garrett: I can say nothing more than that I grant the jury their application. The accused is discharged.

OTOGRAPHS OF PLAYS.—Mr. Justice Kekewich, in the Chancery ion last week, had before him a motion in the action of the r Street Studios and Adart (Limited) v. Vincent and Bancroft, injunction to restrain the defendants, the publishers of "The tre" magazine and "Book of the Play," from publishing illus- ons of photographs of any play not photographed by the plain- and for publishing illustrations of the play, "Mr. Sheridan," air magazine.

P. Ogden Lawrence, K.C., and Mr. Harold Simmons appeared e plaintiffs; and Mr. Ashton Cross for the defendants.

appeared that by an agreement between the photographers and ublishers, dated September, 1906, it was provided that in the f the photographers not being able to furnish for any issue e "Book of the Play" a photograph of a successful play then ing in London, the publishers were to be at liberty to buy for cation in the open market any photographs of a play that could ured by them. By a second agreement, dated January 7, 1907 h Mr. Justice Kekewich said was meant to vary that provision), ublishers undertook not to publish any play not photographed e photographers unless the latter could not supply a successful

One of the defendants, Mr. Bancroft, alleged that the plain- romise to supply them with photographs of "John Glayde's ar," at the St. James's Theatre, for the April number of the ine, but Mr. Hamburger, the managing director of the iff company, stated in the witness box that that was not true. laintiffs, he said, had photographs of "Toddles" and of "The ger Sex," both of which were successful plays, and which they have supplied.

Justice Kekewich said he had come to the conclusion that the ants had not proved that the plaintiffs were not in a position nish photographs of a successful play, and pointed out that ens had been furnished of successful plays. It appeared, there- o him that the defendants' case failed, and he would, therefore, the circumstances, grant the injunction asked for.

OUGHBOROUGH BANKRUPTCY.—Mr. John Grange, photographer abaconist, Loughborough, appeared for his public examination Leicester Bankruptcy Court on April 12, before Mr. Registrar . The statement of affairs filed by the debtor disclosed lia- amounting to £141 2s. 11d., and assets estimated to produce

£112 5s. 3d. Debtor said that four years ago he and a man named Harris started as photographers in a small way. They did not actually take photographs, but secured orders for enlargements of existing photographs, got them done elsewhere, and realised a profit. From Worksop they went to Alfreton, and from Alfreton to Loughborough. There debtor opened a tobacconist's shop, thinking he could probably make a profit out of it. He did not know at the time he opened the shop that two other tobacconists previously in the shop had failed to make it pay. The examination was closed.

ILFORD, LTD.—The directors of this company have declared an interim dividend at the rate of 4 per cent. per annum for the half-year ending April 30, 1907.

## News and Notes.

A LIST OF GERMAN TRADE NAMES.—Our Dresden contemporary, "Die Photographische Industrie," deserves the thanks of the photographic trade for compiling a list of the trade or fancy names, which, in the German market, are bestowed upon the apparatus and materials of photographic utility. The list is a re-issue bringing a former publication up to date.

TRAVEL EXHIBITION, 1907.—Now that the facilities for travelling by various methods, both at home and abroad, are so great and the difficulties practically nil, the above exhibition, which will be held in the Royal Horticultural Hall, Westminster, under the auspices of the "Health Resort," from May 18 to June 8, will probably appeal to a very large number of our readers, and the response to both the loan and photographic sections doubtless correspondingly numerous. With regard to the former, the committee solicit the loan of old prints, engravings, photographs, models, curios, etc., depicting travel in any form, and all communications with regard to these should be addressed to the Organising Manager, Exhibition Offices, 75, Chancery Lane, London, W.C. The photographic section is under the management of Mr. F. J. Mortimer, editor of the "Photographic News," and consists of two classes, in each of which prizes of two guineas, one guinea, and 10s. 6d. will be given for the best pictures of any method or incident of travelling, whether by water, road, rail, air, etc., Class A being for pictures taken in the British Dominions, and Class B for those taken in foreign countries. Special prizes of one guinea and 10s. 6d. will also be awarded in each class to competitors under twenty years of age. Entry forms for the competition, which closes April 30, may be obtained on application to the editor, "Photographic News," 9, Cecil Court, Charing Cross Road, London, W. The envelope should be marked "Travel Exhibition, Photographic Competition."

A BOOK illustrative of the trades and industries of Brandenburg has been issued by Herr Friedrich Schroeder, of Brandenburg. A large proportion of the negatives, particularly of the interiors and the badly-lighted workshops, were made by the flashlight apparatus of Herr Schroeder, which is now being sold by the large English dealers.

HULL PHOTOGRAPHIC SOCIETY.—The officers for the ensuing year are: President, Mr. W. H. Willatt; secretary, Mr. T. J. Webster, 96, Witham Road, Hull; editor and librarian, Mr. W. Gilleard, 18, De Grey Street, Hull; members of council, Messrs. W. S. Parrish, J. T. Dyson, W. Dalton, D. L. Cockcroft, J. W. Atkinson, and J. W. Bolton.

"ARGO" PAPERS.—Messrs. A. E. Staley and Co. announce that they now hold a large stock of "Argo" gaslight, "Monox" bromide, and "Disco" P.O.P. papers of the Defender Photo Supply Company, which may be obtained from all the leading photographic dealers, or direct from the above firm, at 19, Thavies Inn, Holborn Circus, London, E.C.

THE EXHIBITION OF PHOTOGRAPHIC APPARATUS, organised by The Service Company, Ltd., was opened on the 15th inst., at their offices, 292 and 293, High Holborn, London, W.C., and will continue open till April 27. Among the firms represented are Messrs. Ross, Ltd., Newman and Guardia, Ltd., Voigtlander and Sohn, C. P. Goerz, Shew and Co., The Aerograph Company, Wrench and Son,

C. Zimmermann and Co., Houghtons, Ltd., Butcher and Sons, J. H. Dallmeyer, Ltd., The Thornton-Pickard Manufacturing Company, The Altrincham Rubber Company, Marion and Co., Ltd., W. Butler, Ashford, Ltd., Aston and Mander, Wellington and Ward, Ilford, Ltd., Rajar, Ltd., The Adhesive Dry Mounting Company, Ltd., Kodak, Ltd., J. Lizars, Watson and Son, and W. Tyler, Ltd. Many of the above-mentioned firms have arranged to give frequent demonstrations of their specialties, which should prove both interesting and instructive, and we feel sure that all visiting the exhibition will feel well repaid for so doing.

M. TANQUEREY AGAIN.—Quite a number of readers have sent us within the past few days the batch of circulars which M. Tanquerey, the doyen of free portrait swindlers, is evidently delivering broadcast in the London districts. There is nothing new in his "bona-fide" (!) offer of an enlarged portrait for nothing, yet the audacious fraud seems destined to enjoy perpetual youth. M. Tanquerey's genius for manufacturing testimonials is seen in the testimonial alleged to be from "Truth." "I am with Monsieur Tanquerey, and cheerfully say 'Hurrah,' pour l'Entente Cordiale, for no one values it more than I do. I wish Monsieur Tanquerey all the success he deserves." There is a subtle vein of humour in the last sentence, for no journal has more emphatically exposed Tanquerey as an impostor than our contemporary.

## Correspondence.

### THE VARIATION OF TIME OF DEVELOPMENT WITH TEMPERATURE.

To the Editors.

Gentlemen,—For some time past I have been in the habit of developing all exposures in a tank with rodinal, diluted 1 in 100, and using a Watkins' factor of 40. For my amusement and instruction I have also noted the temperature of the solution and the total time of development. Your issue of the 5th inst., and your answer to a correspondent in the current number have suggested to me to investigate the data that I have obtained.

The results interested me, and I am writing this in the hope that they may prove equally interesting to some of your readers, and may further induce others to give their ideas on the subject.

I find Colonel Houdaille's law confirmed between 12 deg. C. and 12 deg. C. nearly enough for all practical purposes, and append a table showing the results:—

t deg. C.	T mins.	T according to Houdaille, assuming time at 18 deg. C. to be correct and neglecting fractions.
24	30	29
22	33	33
20	37	37
18	41	41
16	45	45
14	50	49
12	55	54

The law that my results follow very closely is:  $T = -84 \log. t + 146$ , where T = total time of development in minutes, and t = temperature of solution in degrees Cent. Between 24 deg. C. and 12 deg. C. this is approximately a straight line.

I may mention that the developer has been accurately measured in a well calibrated flask, and that one brand of plate has been used throughout.—I am, Sirs, yours faithfully,

HARVEY COLLINGRIDGE, B.Sc., A.M.I.C.E.

55. Hornsey Rise Gardens, Crouch End, N.  
April 12, 1907.

To the Editors.

Gentlemen,—This question is an important one, and therefore possibly you will allow me a little space thereon, with particular reference to the query propounded to you by "Q. S." on page 2 of your last issue.

M. Houdaille's statement is said to have been founded on a development of over 3,000 plates, presumably many of them with a particular sector wheel which he devised. It is obviously the more worthy of some attention, although, as you justly point out, mathematically correct.

I used this method for roughly estimating the effect of temperature on the duration of development for over a year, and found at length that it gave me a much better guide to the actual duration required and that I obtained better results and more certain than when neglected the temperature factor altogether, as so many amateurs do.

The most useful paper on the subject was, I think, one read by Mr. W. B. Ferguson, K.C., M.A., before the R.P.S., and reported in the "Photographic Journal" for May, 1906. In this Mr. Ferguson referred to a previous paper by him and Mr. Howard, and he gave the following rule, which is practical: Take the shortest time of development (that for 17 deg. C = 65 deg. Fahr. was taken), and multiply by 1.05 (1.05)<sup>2</sup>, (1.05)<sup>3</sup>, and so on, for decrease in temperature by 1, 2, 3, and so on degrees. In a table given it is shown that the calculated time differed from the experimentally proven time by at the most 3.6 per cent.

Towards the end of his paper, after a series of mathematical calculations, he states that the simplest way to find the duration of development to give a determined density at varying temperatures is to subtract the log. of the temperature coefficient, which he found to be 0.01706, from the log. of the time taken to obtain the given density at a known temperature. To save time one may naturally calculate it for every two degrees, and the above factor becomes 0.0341. It is obviously not necessary to go beyond four places log.s.

Examining by this rule M. Houdaille's statement, it will at once be seen that there is a big error; assuming then that the total time of development was 300 secs. for 15 deg. C., we get

log. 300	=	2.4771
		.0341
2.4430	=	log of 277 secs. at 17 deg.
.0341		
2.4089	=	log. of 256 secs. at 19 deg.
.0341		
2.3748	=	log. of 237 secs. at 21 deg.
.0341		
2.3407	=	log. of 219 secs. at 23 deg.

In your reply Houdaille's time is stated to be 180 secs., which is a big error as compared with 219 obtained as above.

The trouble, however, lies in the fact that Mr. Ferguson used pyro-soda, whereas Houdaille used, I believe, hydroquinone, and the same factor may not apply.

Again, in the little pamphlet, entitled "Real Orthochromatism," issued by Messrs. Wratten and Wainwright, it is stated, "Suppose for the plate given, that you wish to develop a negative of an architectural subject, and that your developer is 60 deg. Fahr. in temperature. This temperature is not mentioned, but if it were 65 deg. you would develop for 5½ minutes; if it were 50 deg., for 7 minutes. At 60 deg. take a point in between and develop for 5¾ minutes." It is true that the developer recommended is a very weak metol-hydroquinone, but it is also stated that a pyro-soda of practically H. and composition requires the same time.

Examining this statement by Mr. Ferguson's second rule, then we get 4¾ minutes for 60 deg. and practically 4 minutes at 65 deg. assuming that I have made no mistakes in my calculations.

I have looked in vain for any further communications from Mr. Ferguson, dealing with other developers, but possibly he or Dr. M.

may help us now, and give us a simple rule which can be applied to anyone to various developers.—Yours faithfully,

PAUL M. CRANSTON.

#### PROFITS ON PICTURE POSTCARDS.

To the Editors.

Gentlemen,—I read "Another Postcard's" letter in your issue of the 5th inst. I conclude the writer does not publish his own postcards. If he does I am surprised at his taking negatives for others at 2s. each, even by the dozen. This is the style of thing that brings photography into disrepute. I note he says he has taken 200 or 300 negatives for local publishers or publishers in the neighbourhood. By this I gather he refers to local booksellers or stationers, some of whom print their own cards, after a style. It was not publishers of this type I referred to as competitors with the local photographer, but rather the firms who, if they get good negatives, can turn out first-class work. It pays these to pay for good work, or, if they cannot get it, to send their own man; but in either case I submit it ought not to be possible for them to secure a series, say, of dozen half-plates at the absurd price of 2s., or even 5s. each, and if they send their own man from any distance I question if they would cover the expense at that figure. As a rule, I believe they pay them better when possible to have the pick from good negatives already taken, and pay for the copyright, but, as I previously said, when a number is taken, even these sometimes demur at the Copyright Union's minimum fee of 10s. 6d.

It is very well for Mr. Corkett to advise photographers to specialise. I think he would find that such does not pay, except in large business centres. I hope that the number of editors is getting less who prefer cheap and nasty photographs to the good for illustrations. Though the first cost is higher, I believe they are finding the result is worth the difference.

PROFESSIONAL.

#### NEW METHOD OF MEASURING THE TIMES OF PHOTOGRAPHIC SHUTTERS.

To the Editors.

Gentlemen,—In your issues of December 17, 21, and 28 last there appears, under the above heading, the report of a paper read before the Optical Society on November 15, 1906, by Mr. J. De Graaff Hunter, of the National Physical Laboratory, where the work was undertaken to provide a test for measuring the speeds of photographic shutters.

In the discussion which followed the paper I notice that my name is introduced by one of the members, who said that he considered Mr. Hunter's machine a modification of the apparatus which I patented some few years ago. In his reply, Mr. Hunter said he did see my patent, but he considered it so different from his (Mr. Hunter's) that he made no reference to it. Continuing, he said that image was formed or used in my apparatus, as in that described to him; also that I do not measure periods shorter than the persistence of vision, and that his apparatus may be used with a camera, &c., for a photographic test.

My specification particularly and clearly states that the image is to be projected, seen, or photographed, and that for periods longer than the persistence of vision, estimates of the relative lengths of the dark and light portions of the slit can be made.

I am afraid that if Mr. Hunter has seen the specification of my patent it must have been in a very casual way, or he would not have been likely to have used the arguments reported. But after reading Mr. Hunter's paper through I feel convinced that he must have seen it, as I consider the methods he describes are my own, and his apparatus an infringement of my patent (No. 16,053, 1904), which is still in force. The only modification I can see in Mr. Hunter's machine is the mechanical trip to release the shutter, which is a doubtful improvement, and is more likely than not to introduce errors. It would be a most difficult and impracticable method to adopt when different kinds of shutters were being tested.

A reading of the paper conveys the impression that it is a method which is free for anyone to use indiscriminately, but in point of fact the use of the method without permission may lead the user or users to litigation.

I think your readers may wish to judge for themselves from the facts of the case.

After applying for my patent and knowing the difficulty which there had been in devising a satisfactory method of measuring the speeds of photographic shutters, I wrote to the National Physical Laboratory, calling their attention to the work I had been engaged on, and at the same time offered to visit the laboratory and explain my methods to them. In their reply, dated April 12, 1905, they said that the subject was of considerable interest to them, and accepted my offer to go to the laboratory. In due course my patent agent, Mr. Griffith Brewer, and myself went to the National Physical Laboratory, and explained to the principal and the staff the details of my work on this subject.

My next intimation on the subject was the above article by Mr. Hunter, and I most strongly protest against what I consider the appropriation of any honour or credit due to my work on this subject, for when explaining to the principal and staff the details of my work it was stipulated and conceded to me that due recognition should be given me as first user and inventor.

Even had Mr. Hunter modified his apparatus sufficiently so as to evade my patent claims, I could not have seen the justice of one Government department granting a protection and another department setting their heads together to break it up, nor do I consider that the National Physical Laboratory was ever instituted with any such competitive ideas in view. It is surely not unreasonable that under the above circumstances an explanation should be forthcoming.

A. KERSHAW,

Photographic Apparatus Manufacturer.

St. Columba Street, Leeds.

April 10, 1907.

To the Editors.

Gentlemen,—Mr. Abraham Kershaw, of Leeds, has drawn my attention to a point in connection with my paper, under the above title, which was published in your issues of December 14, 21, and 28.

To avoid misunderstanding it is desirable to point out that the fundamental principle on which the determination of shutter speeds depends is that of converting the measurement of time into one of distance. That is, if we cause a luminous object to move in some known manner, and find how far this object has moved while the shutter is open, we can deduce the time of the shutter. In order that only the motion which takes place while the shutter is open may be measured, it is only necessary to obscure the object by means of the shutter. The moving luminous object may be replaced by an illuminated surface, different portions of which are visible at different times through a slit moved over the surface. In any case, the measurement which has to be made is one of length, and the main difficulty of carrying this out is that it has to be done instantaneously.

Mr. Kershaw, in 1904, patented an apparatus for testing shutters in which a strip of light and a rotating disc with radial slits were used. By looking through a shutter and through the slits of the disc at the strip of light, and adjusting the speed of the disc so that the strip of light became wholly visible, Mr. Kershaw determined the length of time for which the shutter was open. He made use of the principle of persistence of impression on the retina to determine when the strip of light became wholly visible. Mr. Kershaw also states in his complete specification that "for estimating slower speeds than 1-10th of a second, estimates can be made of the dark and light portions of the slit," while, "if desired, instead of viewing the action with the eye, a photograph can be taken of it, or it could be projected direct on to a screen"; but he does not refer to these methods of working in his claim.

The method described in my paper also involves the use of a rotating disc with radial slits; but only a single slit is used in observations of any particular shutter speed. A mechanism is described whereby the shutter is always released when this slit occupies a definite position, with the result that the image seen is fixed in position, and its length can be measured, not merely estimated, by means of a device which is fully described.

My early experiments had shown me the necessity of this arrangement, and it is this that constitutes the main novelty of the paper.

I regret I did not refer in the paper itself more particularly to Mr. Kershaw's method, and thus render the difference clear, more especially as I mentioned the possibility of making results depend

on the persistence of vision, the method which Mr. Kershaw advocates.

In the discussion which followed my paper, Mr. Conrad Beck spoke of Mr. Kershaw's patented method, and I replied that it seemed so different from my own that I had made no reference to it. On further consideration, I think it is right to make this statement to make it clear that I had no wish to claim as mine any device which had previously been used by Mr. Kershaw.—I am, Gentlemen, yours truly,

J. DE GRAAFF HUNTER.

Bushy House, Teddington, Middlesex.

April 13, 1907.

#### RELIEF EFFECTS IN PHOTOGRAPHS.

To the Editors.

Gentlemen,—I read with interest in your issue of April 5th (page 250) your explanation as regards the false effect of modelling caused by photographing medals and coins upside-down, causing the light to fall from bottom of same towards the top, but the enclosed two pages of catalogues—taken from the two first to hand—proves that it is not always the "poor photographer" at fault.

In these cases, and I have noticed several, the printer, by simply reversing block (having nothing but the lighting of same to indicate top and bottom), has conveyed quite a reverse impression to what the frame is described, viz., *hollow oak*, this effect only being obtained by viewing page *upside down*.—Yours truly,

GORDON CHASE.

1 and 2, The Broadway, Tunbridge Wells.

April 15, 1907.

[The effect is very prominent in the examples sent by our correspondent, and we have no doubt others can be found in current lists of frames.—Eds. B. J.]

#### UNIFORMITY IN HALF-TONE NEGATIVE MAKING.

To the Editors.

Gentlemen,—I was much surprised on reading the report of Mr. E. C. Middleton's paper before the R.P.S., in the current issue of the *BRITISH JOURNAL*, to find myself accused of pilfering from the lecturer.

In answer to that charge, I must most emphatically state that until I read his paper I had not the slightest idea what Mr. Middleton's methods of operating consisted of. Although I have known him for many years, it has been chiefly by repute, and when I have met him the subject has not been discussed between us, and as for obtaining his ideas indirectly, if anyone except himself knew of his methods, it has not been my fortune to meet them.

With regard to his writings in 1875, this was long before my advent into photo-engraving, but I do remember reading an article by Mr. Middleton, in the *BRITISH JOURNAL* for February 22nd. 1895, which dealt with the various effects to be obtained with different shaped diaphragms, but, strange to say, a fortnight previously, an article had appeared in the *BRITISH JOURNAL* from the late Mr. W. K. Burton, then in Japan, which gave an account of the work being done there, and which practically gave all the same facts. Yet no one suggested that Mr. Middleton had copied from him.

As a matter of fact, my method, which I described in the "Process Year-Book" for 1906-7, has been evolved from a table which I published in 1904, and which I had had in use in various forms since 1895, which gave the same method, but illustrated it in a different way, and the fact of us both using the same figure to illustrate our ideas is merely a coincidence, as I only discovered during the autumn of last year that I could adapt my table to that figure; but I had often used the long wedge to illustrate to an operator or other interested person in a simple way, just what happened in the camera, but when once discovered it seemed to me so very obvious that I wondered that no one had ever published it before.

When next Mr. Middleton and I meet, I have no doubt that we can settle the question amicably enough, but as the statement was publicly made and published, I must ask you in common fairness to myself to give me a little space to speak in my own defence.—Yours faithfully,

E. A. BIEMANN.

63 and 64, Ludgate Hill, Birmingham.

April 15, 1907.

## Answers to Correspondents.

\* \* All matters intended for the text portion of this *JOURNAL*, including queries, must be addressed to "THE EDITORS, THE *BRITISH JOURNAL OF PHOTOGRAPHY*, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\* \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

H. Abba, 43, Holderness Road, Hull. *Photograph of the Rev. G. A. Parkinson, Photograph of a Group of the Rev. G. A. Parkinson, and Messrs. J. A. Meale and H. R. Holcombe.*

E. Ellis, Wellington, Milltown, Malbay, County Clare. *Photograph of R. C. R. L. Ellis.*

R. Brown, Church's Mansion, Nantwich. *Two Photographs:—Mr. R. Corbett and South Cheshire Hounds at Wistaston, Cheshire, and at Cholmondeley, Cheshire.*

W. Freeman, 132, Above Bar, Southampton. *Two Photographs of s.s. "Suevia" under own Steam and Towed to Dry Dock, Saturday, April 6, 1907. Stern Portion.*

W. McQueen, 7, Oldham Road, Royton, Lancashire. *Photograph of Henry Taylor, World's Amateur Champion Swimmer.*

#### DRAWING REGISTERED:—

G. Cross, 341, Lord Street, Southport. *Drawing of a Scheme for laying out the Lagoon, Southport.*

SECONDHAND APPARATUS.—(1) Where, and for how much, can I buy a "Royal Ruby"  $\frac{1}{2}$ -plate or 1-1 camera, fitted with "Ross" homocentric lens, secondhand? (2) Is there any chemical dictionary (English-Latin, as the chemist terms the chemicals) on the market? If so, kindly give an address and price.—HOMO.

(1) The City Sale and Exchange, Fleet Street, E.C., or Sands and Hunter, Bedford Street, W.C., are dealers in secondhand cameras, etc.; but it is doubtful if either can supply you with the new model of the "Royal Ruby," nor are you likely to get a great reduction of price on the lens. (2) The "British Pharmacopœia." We do not know a smaller work.

DARK VIGNETTES.—Would you be good enough to give me the address of those who supply the attachment for camera that enables one to make those dark vignettes?—ANXIOUS.

Kodak, Ltd., Clerkenwell Road; Marion and Co., 22-23, Soho Square, W.; in fact, any of the large dealers.

PROGRESS.—Mouldings, of Sichel and Co., 52, Bunhill Row, E.C., and Thomas Illingworth and Co., Willesden Junction, N.W. Glass: Hetley and Co., Soho Square, London, W.C. Prints: Spooner and Co., Strand, W.C.

G. B. (Dover).—The three prints are certainly very good in vigour and tone, and the process is evidently very simple and inexpensive. We would say, however, that there is at least one paper on the market which gives similar results on fixation only. It is difficult to say whether there is a commercial success in the paper without having tested it.

CANADIAN PHOTOGRAPHIC JOURNAL.—Can you put me in touch with a Canadian photographic journal, as I wish to advertise in the same?—OPERATOR.

"St. Louis and Canadian Photographer," 3,210 Locust Street, St. Louis, Mo., U.S.A.

CASKET LENSES.—(1) Can satisfactory results be obtained by the use of casket lenses equal to results by the use of lenses especially adapted to various requirements? Your advice will be much appreciated as to what make and price to purchase, and any other information you may be kind enough to give concerning these casket sets.—WIDE-ANGLE.

(1) Casket lenses can never possess the corrections of an anastigmat, but for work where the negatives are not to be enlarged

lenses will give most satisfactory results. The drawback is the fact that at the longer foci the rapidity is low. Must say that our own preference would be for an anastigmat of moderate aperture ( $f/8$ ) if price is a consideration—the single elements of which could be used separately. (2) Many of combinations formed by a casket set will cover a much larger area, but an actual test is the only guide.

**TONES.**—Can you kindly inform me how a "blue" print is converted into green—I mean an ordinary lantern slide is converted to blue by the iron process? How can this be turned into green colour?—E. Y. E. N.

There is no certain method. A strong solution of potassium ferrioxalate, containing a little acetate of lead, will turn them green (damp destroys the colour), but the best plan is to tone the uranium-ferricyanide bath until very dark and dense, and keep in a weak solution of ferric chloride. This bath gives as well as tones, hence only a brief immersion must given.

(Lausanne).—The two books are distinct works.

**TRANSFER CARBON PRINTING.**—Enclosed is a sample of mine. Since starting this process, about three months ago, I have got on all right until now. Prints refuse to leave the supports, with the result you see. The waxing is done as when they were proved all right. (1) Can alum bath be too strong? What is the correct proportion for fixing, also for solution in which the supports are soaked? (2) Should alum bath be used more than once?—R. D.

(3) No; the strength is very immaterial—5 per cent. is about usual. The final support is simply soaked in warm water, at 90 deg. to 100 deg., until it assumes a slimy feel. (2) It may be used many times until it becomes of a yellow tint. Your trouble may proceed from more than one cause. One is that the temporary support was imperfectly waxed. Another is that the final support was insufficiently softened, or was made too soft. I rather suspect that the last-named is the cause of the trouble in the present case. Just allow the final support to become slimy on the surface, and then squeegee on the picture, taking care to remove bubbles.

**MARKING.**—We beg to work the following on you: (1) Kindly send us the address of the makers of the machine for making plate-sunk mark of enclosed postcard. (2) Do you reckon the negative is masked with paper or painted round, and the name at the bottom cut through the paint. (3) The receipt of a good workman for blocking out backgrounds on negatives; if possible one that will wash off.—Cosm.

(4) No special machine is necessary, as an ordinary rolling mill suffices. Cut a plate of zinc or copper to the size of the negative desired; put on the bed of the rolling press as on that the print. Back up with two or three thicknesses of printer's sheet, and pass through the press. (2) The title is usually made by transferring a negative photograph of the wording which has been set up in type, afterwards masking out the rest of the negative with blocking mixture or the commercial "photopake." The ordinary black varnish, as sold by the dealers, is what is usually employed for the purpose, and we should advise you to get that instead of attempting to make for yourself. It is very inexpensive.

**ART.**—A leading music-hall artist has placed with us four hundred photographs, which he wishes us to copy and produce as cards for public sale. He assures us he has all rights for reproduction, but we wish to ask you if this is sufficient for us to place them on the market with our name on—i.e., The Honora Series. We may say for your information that the original photographs were taken by a very well-known firm. We do not do anything unfair as regards the copyright, hence our inquiry.—CARBONORA.

It is more likely than not that the copyright is not the artist's, but the photographer's. In the event of your making or using the postcards you would be liable to action for infringement. The artist should be asked to furnish proof of ownership of the copyright in the shape of a receipt for the sitting from the photographer's; but a better course would be to apply to the firm for confirmation of the artist's assertion.

**ONWARD.**—We doubt if you will be actually better off in the States than you are here. We certainly should not go to America for comfort. We advise you to read the accounts of professional photography in the States, such as we published in our issue of May 11 last year.

**RESIDUES.**—I have a quantity of old hypo fixing bath, and want to recover the silver in it. (1) Is it sulphate of copper used to throw it down, and (2) is it taken to the refiners in the wet state or baked dry?—OLD HYPO.

(1) Useless. The proper substance is "liver of sulphur" potassium sulphide, which precipitates the silver at once. The silver settles in a few minutes. (2) The precipitate can be drained of water or sent wet to the refiners or dried. It is a matter of convenience.

**CHEMISTRY.**—Two years ago I started business as a photographer on my own account. My knowledge of chemistry is practically nil. Can you refer me to some good book or books dealing with chemistry generally, and particularly in its relation to photography? Where can I get such, and what are prices—P. T. M. Better get "Chemistry for Photographers," by C. F. Townsend (Dawbarn and Ward, 1s.), for a start.

**MANXMAN.**—Pure resin, 1 oz.; oil of turpentine, 1 oz.; oil of lavender, 2 oz.

**PYRO DEVELOPER.**—Will you please give me the formula for a good all-round pyro-soda developer that will keep when made up in large quantities, and kept in glass-stoppered bottles. At present I make it up with soda sulphite and sulphuric acid as the preservative, but, in a short time, it discolours and loses strength.

The following, of Mr. B. J. Edwards, is a good formula:—

No. 1.	
Pyro .....	1 oz.
Metabisulphite of soda .....	1 oz.
Distilled water, to .....	80 ozs.
No. 2.	
Sulphite of soda (Boake's) .....	10 ozs.
Carbonate of soda .....	10 ozs.
Water (distilled), to .....	80 ozs.

For use, mix equal parts of No. 1 and No. 2. The mixed developer may be used full strength or diluted, according to the density required in the negative. For studio work it usually works best at about half strength. Development is complete at 65 deg. Fahr. in about five or six minutes. The addition of bromide increases contrast, but does not materially prolong the total time of development. There is no pyro stain.

**CIGARETTE.**—(1) Yes, quite for general purposes. (2) If you want to take very large groups a couple or three feet wider would be a little advantage, but for general work is quite unnecessary. (3) To X would be a good height, but for large groups it might be a foot or two higher, as then the light would be better diffused when the whole width of the studio was required to be fairly equally illuminated. (4) With that width of studio the front light will not be necessary. If you have that part glazed we should advise ground glass, which can be stopped off if not required. (5) We should say that clear glass should be used; it is cheaper, and, as you say, can be blinded off if the sun proves troublesome at times.

**ENLARGING QUERY.**—I have recently started enlarging, and find that when I enlarge from a retouched negative the retouching marks show, and when I enlarge from a copy negative the grain shows. I may say that the retouching is done by an extra good retoucher.—ENLARGER.

Of course, if the image is sharply focussed, anything that is sharp in the negative will appear sharp in the enlargement. You do not say if you employ diffused daylight, or artificial light with a condenser. If the latter, the retouching will show more sharp and crude than if the former were used. The effect may be greatly softened by making the enlargement slightly out of focus, or by using a lens possessing a good amount of spherical aberration, and used with a large aperture. We should have thought this was thoroughly understood by all enlargers.

**NEGATIVE PAPER.**—1. As I know that negative paper has been put on the market, I write to ask whether it could be used success-

fully for ordinary commercial photography (such as postcard work), or would the grain be too much in evidence. I do a great deal of work which renders backed plates a necessity, and the difference in cost is very great. 2. Also, do you know of any make of negative paper which is isochromatic? 3. Do you consider that the anti-halation sheets which are sold are as efficacious for preventing halation as a backed plate—that is to say, a plate bought already backed?—M. D.

Not grain, but slowness of the emulsion is the objection to commercial negative papers. For reproducing from other negatives they should be quite satisfactory, but we believe a glossy bromide paper, such as Wellington and Ward's "Enammo," is better still for such work. We know at least one maker of negatives for postcards whose work is done on negative paper. 2. None that we know of. 3. We consider the anti-halation plates about equal to the commercial backed plate, and both more subject to halation than a plate liberally backed at home.

**CINEMATOGRAPH LITERATURE.**—1. Is there any periodical (weekly or monthly) that deals entirely with the cinematograph; and, if so, where can I obtain the same? 2. Also, if there is any book (complete) later or better than "Animated Photography," by Cecil M. Hepworth.—A. W. ANDREWS.

1. There is the "Cinematograph Gazette," until recently published by Theodore Brown, 26, Drummond Road, Boscombe, but we do not know if it is still published. 2. The only other work is "Living Pictures," by H. V. Hopwood (2s. 6d.), but if your desire is for a book on practical manipulation, we doubt if the volume will be of further assistance to you than Mr. Hepworth's.

**E. J. M.**—We must confess that our own preference is to fight shy of all such compounds. We made tests on bromide papers finished with the aid of the preparation you name, and we were satisfied with the results, but we know nothing of its regular use in practice. We should say, if you can ensure the directions being carried out, it will be quite satisfactory for negatives, though not so suitable for batches of prints, since in this case it is not so easy to ensure equal action on each print.

**TYKE, C. H., and OTHERS.** In our next..

**HEINRICH AND POULSEN.**—We are sorry to say we are unable to trace any firm at present making the anti-halation sheets.

**E. F. SANDERS.**—We should certainly advise you not to think of installing an electric arc light in a room only 8 ft. 9 in. high. You will not get enough vertical height for the lamp to give you the top lighting necessary unless the sitters are invariably seated. You could not rely on reflection from the ceiling for your top lighting.

**STAINED NEGATIVE.**—I have an important negative upon which I had the misfortune to drop a spot of developer (I believe)—hydroquinone and metol, and not noticing it in time, found a yellow stain that absolutely will not print through. I tried the salt and re-fixing for silver stain with no effect. Would you kindly say if there is any other method, supposing it is developer stain? Though why it should stain after well washing and drying, when it does not in the development, I do not understand.—STAIN.

Hydroquinone stain, once it has been produced, is very difficult to remove. You might try the hypochlorite mixture, made by shaking up one ounce of bleaching powder with about six ounces of water containing  $\frac{1}{2}$  ounces carbonate of soda. Shake up and filter and use the solution on the plate. If this fails we can suggest only one other remedy, and that is to make a strong mixture of hypo and glycerine, spread on the negative, and allow the latter to remain for, say, some days, in the course of which time the stain may disappear.

**ANXIOUS INQUIRER.**—The photographs on the whole do you great credit, and are quite equal to the productions of a great many photographers catering for the lower middle classes. As to whether it would be to your advantage to take up photography as a business we cannot express an opinion, as you do not tell us what your prospects are in your present trade, but we would urge you to consider very carefully before making any change, for the reason that photography at the present time requires very good business management to make it pay. If you have busi-

ness talent there is money to be made out of it, quite apart from your technical proficiency.

**STAINED BROMIDE.**—I have a bromide enlargement on India P.S. mount, made about two years ago. The whites of enlargement are all right, but all deep shadows, and at the edges—about  $1\frac{1}{2}$  inches all round—show an oxidised silvery blue appearance. The maker of the picture says he cannot account for it; he carefully fixed and washed it after development, and did not use any iodine for reducing—so far as I can remember. The mount does not show the slightest colouration, and has evidently not been in a damp place. I trust my description is clear to you, and shall be glad to reply as to cause of the fault, and to suggest a remedy if there is one.—LIMERICK.

We have seen something of the kind in prints which have been exposed to products of combustion of gas or other vapours which act on the silver surface. It often takes place also in uranium-toned prints, but we take it in your case that toning has been done. It is possible that by bleaching the print and re-developing the stain would disappear.

**RELIEF PHOTOGRAPHS.**—Would you kindly tell me, through your valuable Journal, how to make a relief negative or positive, and what the relief to be about a 16th of an inch, or nearly PANTONIA.

The greatest relief is obtained with Namias' methods. A solution is prepared of—

Gelatine .....	20 parts.
Gum arabic .....	10 parts.
Water .....	100 parts.
Glacial acetate acid .....	1 part.

Soak the gelatine and gum in the acid water for an hour or two, and then dissolve in a water-bath. When dissolved, through linen and pour on to a levelled glass to the thickness of one-twelfth to one-eighth of an inch, and allow to thoroughly set and dry in a horizontal position. These plates will keep indefinitely. To sensitise them, immerse in a 2 per cent. solution of ammonium bichromate, rendered distinctly alkaline with ammonia. The sensitised plates will keep for ten days. The exposure is from fifteen to thirty minutes in direct sun, and the plates should be placed at the bottom of a light-tight box, so as to use parallel rays as far as possible. The exposure of the plate should be placed in a 2 per cent. solution of alum plus 2 per cent. glacial acetic acid. The plates should be soaked for some hours until perfect relief is obtained. If water is used instead of the acid alum, a coarse grain is imparted to the relief.

**CELLULOID MINIATURES.**—A stationer in my town having asked me to do him a number of the button photographs, I ask you to inform me in this week's "B.J." where I can obtain instructions for giving the prints the coating of celluloid.—TIMP.

The prints are dipped in alcohol and rolled in contact with the celluloid with a hot roller. Messrs. Fallowfield, who make the apparatus, issue a sixpenny book of directions.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received by the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## The British Journal of Photography

The Oldest Photographic Journal in the World.

## SUMMARY.

to give the results of some preliminary experiments on sulphite soda, which show the remarkable differences which different doses of this substance exhibit in solution. (P. 306.)

What is your standpoint? An American professional puts in a strong claim for tasteful printing of photographers' stationery. (P. 307.)

Mr. C. H. Hewitt contributes some practical notes on the methods producing portraiture in which the drapery is subdued whilst the sitter's head is fully lighted. (P. 312.)

A series of portrait reproductions in a weekly newspaper suggest striking effects which photographers can get by suitable mounting. (P. 305.)

A correspondent further discusses the epidemic of blisters in bromide papers, which is an occasional inconvenience to bromide workers. (P. 321.)

A show-case idea, which may be of service to professional photographers, is mentioned on page 305.

An exhibition very completely representing the photographic trade as the "Tribune" Rendezvous on Monday next. (P. 317.)

An American worker speaks highly of the kallitype process for printing from winter landscape negatives. (P. 314.)

Messrs. Horace and Conrad Beck's recent paper before the R.P.S. commenced on page 309, and discusses the properties of the new Rostigmar lens in relation to the Petzval condition.

A foreign patent relating to formaldehyde suggests the possibility of a compound being placed on the market in tablet form. (P. 306.)

Belagney has recently given formulæ for the use of his acid developer. (P. 308.)

A method of pigment printing, based on Herschel's iron printing process, has been suggested by a French worker. (P. 306.)

## EX CATHEDRA.

**A Lesson in Contrast Mounting.**

Our lively and well-edited contemporary, the "Sketch," is just publishing a series of portrait studies which should be seen by our readers. The series is entitled, "Studies in Ebony and Silver," and each reproduction consists of a half-tone portrait of a lady of the stage surrounded by a solid black border. The striking effect, which fully bears out the title, is obtained by the delicate light tones which make up the whole of the enclosed half-tone portrait. Evidently the negatives were taken specially to secure a print with not a deep shadow anywhere in it—in fact, with all the tones at the upper part of the scale and only a few degrees lower than the highest light in the subject. The intense contrast afforded by the dense black border gives a particularly silvery appearance to these light tones, and the effect is heightened by a little wash-drawing which is done on the photograph and allowed to spread over on to the black border. Still more striking prints are, of course, obtainable when using actual photographs—namely, delicate matt bromides, such as those on the recently issued Barnet "Oyster Shell," mounted on the blackest and mattest of mounting papers. There is a good deal of difference in papers, and one can experiment with a good many of the commercial matt black papers which are purchased in the ordinary way before finding anything approaching a dead-black so closely as does Lindenmeyers' Matt Ruskin Special Black.

## Displaying Goods.

We are by no means in love with any suggestion which proclaims a photographer acting upon it as the borrower of methods from purely commercial businesses; nevertheless, almost any expedient which does actually succeed in giving to the photographer's show-case a character which the passer-by cannot overlook, is infinitely better than the monotony and convention which are conspicuously prevalent. We may, therefore, mention a show-case which we came across the other day in a London thoroughfare which at once fixed our attention, and that, as we stopped to observe, of the passers-by generally. The glass front of the case was covered on the inside with a matt black paper, save only for a circular space of about 8 in., which was left clear, and afforded a view of a portion of the interior. The inside walls of the case were likewise covered in black, with the result that the article displayed a box of cigarettes—was very prominently brought before the passer-by. One or two words of explanation served to fix the name of the brand in the observer's mind. With variations, the idea could be effectively used for photographs, and would be a good deal better than many of the miscellaneous assortments of prints which pass for show-case displays.

### The Evolution of Processes.

It is extremely interesting sometimes to trace the evolution of a process and the ramifications which a completed process may lead to. A statement may be made, or the details of an experiment recorded in a paper, and the value of it may lie unheeded for several years till it is directly or indirectly applied by another worker. A rather striking example of this is to be found in Mr. Howard Farmer's note, first published in 1893, that metallic silver would, when imbedded in bichromated gelatine, render the latter insoluble, without any light action. Mr. Manly's Ozobrome process is obviously a modification and practical application of Farmer's process, which previously had not been utilised. Another application is that described in a recent issue, in which a pigment tissue mixed with silver bromide is exposed to light, and then developed chemically so as to produce metallic silver, being finally treated with bichromate, so as to obtain insolubilisation of the gelatine in contact therewith.

\* \* \*

### Ozobrome without Bromide.

The latest modification, though we are not prepared to say advance, has been suggested by M. Coustet. He has harked back to Herschel's process of 1840 for producing his silver image—that is to say, he coats paper with a 20 to 30 per cent. solution of ammonio-citrate of iron, dries, exposes until a weak image is distinctly visible, then paints the print with a 1 per cent. solution of silver nitrate, and thoroughly washes. He has thus obtained a silver image practically without any vehicle. Carbon tissue is now immersed in a 1 per cent. solution of potassium bichromate plus 1 per cent. potassium ferricyanide, the silver print squeezed down to the wet tissue, and left for an hour. At the end of that time the carbon tissue is rendered insoluble, and may be treated in the usual way. It will be noted that there is no potassium bromide used, though from 0.5 to 1 per cent. may be added to the above bichromate bath to give greater contrasts.

\* \* \*

### Cheap Parisian Photography.

Paris, it appears, is not unlike other great centres of population in not being exempt from photographers whose work is done at a price which is so low as to be incompatible with honest trading or with adequate payment of labour. According to a correspondent of the "Photographisches Wochenblatt," there are a number of studios in the French capital where you may have a dozen carte photographs of yourself for 1½ fr. (1s. 3d.), or a dozen cabinets for 3 fr. (2s. 6d.). According to the writer, the work is of a very low order, mostly the production of improvers, but the public is induced to ascend in the elevator to the studio by the show-case, full of excellent portraits, which is displayed on the street level. The studios do a brisk business for a time, and then, when patronage falls off, one fine morning comes when M. le Locataire is discovered to have gone, leaving, most probably, one or two accounts which in the unavoidable hurry of departure he has been so unfortunate as to have forgotten to pay.

\* \* \*

### Tablet Formaldehyde.

This has been termed an age of tablets. Certainly the great convenience, both as regards economy of space and portability of this particular form of chemical, has led to its just appreciation. From a recent patent it appears likely that we may soon be able to add to our existing stock of photographic tablets, one of which, on solution in water, will give us a solution of formaldehyde, for it has been found that a mixture of an alkaline peroxide or per-acid with para-formaldehyde will, on solution, give off formaldehyde. Naturally, the original idea of the patent is to provide a convenient and portable disinfectant. If barium

peroxide and para-formaldehyde are mixed, there is so much heat generated that the solution boils, and steam and formic aldehyde are given off. With sodium peroxide the heat evolved is so great that the mixture may take fire, but the action with strontium peroxide is much less energetic, though in the two former cases, naturally, the use of plenty of water would distribute the heat evolved.

### Three Varieties of Perspective.

Dr. M. von Rohr has recently classified the perspective effects produced by vision through lenses in a somewhat novel fashion, and has thereby drawn attention to an effect that has probably seldom been noted. His first class is "Entocentric" perspective, in which the near parts of an object appear larger than the more distant ones. This is what is popularly styled "perspective," and it is always produced so long as a real point of sight in front of the object is employed. The photographic image is thus in "entocentric" perspective. The next class is "Telecentric" perspective. In this the point of sight is at an infinite distance, and the effect corresponds with what we commonly style an "orthographic projection" or "elevation" of the object. We do not usually style it perspective at all, but the effect can be very nearly produced with a telephoto lens, and can be observed in a microscope or telescope, or through a single lens if the eye is placed at the principal focus. Owing to the fact that this is the effect given with the microscope, it is often stated that the microscopic image shows no perspective or foreshortening. The third class is styled "Hypercentric" perspective by Dr. von Rohr, and in this the existence of a virtual station-point beyond the object is assumed. If we placed a ground glass between our eyes and a "solid" object, such as a wire cube, and observed upon the screen a shadow of the cube cast by a small source of light situated beyond the object we should see a "hypercentric" perspective representation. This may seem a very theoretical and unpractical system of perspective, but, as Dr. von Rohr points out, it actually exists when we observe a solid object through a single lens, or magnifier, with the eye behind the rear principal focus. It is very easily observed, but we do not remember seeing any previous reference to it. We may add that it is not due to aberration or distortion, but is a quite inevitable optical effect.

### SULPHITE OF SODA.

READERS interested in this matter will remember letters from various correspondents, some of whom supported our views that soda sulphite did not keep well when dissolved with carbonate of soda, while others expressed a contrary opinion, and gave formulæ and experiences that seemed to prove their contention. Mr. Edwards took the latter view, and very kindly sent us a sample of the sulphite that he is in the habit of using, which sample we have tested (without adding carbonate) against three others of well-known manufacture. The result of the test is that while Mr. Edwards's sample is only the third best on the list as regards initial strength, it is easily first for keeping qualities. The tests were preliminary ones, made with very weak solutions of 0.6 per cent., so as to get as quickly as possible a general idea of the manner in which the solutions deteriorated. The result was that in fourteen days Mr. Edwards's sample contained 33 per cent. of sulphite, while none of the other three had the smallest trace, and it still contained 1 per cent. at the end of twenty-two days. In another set of stronger solutions, all made of the same sulphite, and intended to test the effect of various preservatives, we found at the end of seven days that all contained the original maximum of sulphite, which is about

per cent. It is obvious that Mr. Edwards is using a white that keeps exceptionally well in circumstances that are fatal to other samples. Why it does so is not apparent. The highest priced sample we tried was destroyed in ten days, when the other still retained 54 per cent. of sulphite. Purity, therefore, does not seem to be necessarily advantageous, and it is, of course, possible that the presence of some impurity having a preservative effect may explain matters. These tests afford ample explanation of the discrepancies between Mr. Edwards's and our experiences. The following table shows the percentages of white contained in the solutions after various periods. Sample is Mr. Edwards's and A sample is the one we used in our previous experiments with pyro soda. C and D are expensive and presumably very pure samples:—

	A	B	C	D
Fresh .....	83	86	90	91
Three days .....	76	78	84	80
Four days .....	—	—	69.5	53.5
Nine days .....	11	54	37	0
Fourteen days .....	0	33	0	—
Twenty-two days .....	—	1	—	—

In notes published some weeks ago we contended that the proper place for the sulphite in a pyro-soda developer is the pyro bottle, not that containing the carbonate. The reason why other writers disputed this is apparent from the preceding paragraph, which shows how sulphites vary in keeping qualities, one sample keeping well in conditions fatal to others. All the samples of sulphite we have used contain carbonate in small quantities, and in noting

their changes it has become evident that some reaction takes place between the carbonate and the sulphite or the decomposition products of the sulphite. Experiments with solutions containing a large excess of carbonate also show evidence of reactions of a somewhat different nature. In the case of the latter solutions the rate of change has not yet been determined, the few results obtained being very erratic and inconclusive. For example, in one test no less than 75 per cent. of the sulphite was apparently destroyed within a few minutes of mixing. In other cases about 25 per cent. disappeared in times varying from a few minutes to a day or so. In several cases no effect was observed, while in one the carbonate seemed to act as a preservative. As yet the only points that have been determined are these:—(a) Reactions take place between the carbonate and sulphite which vary in their results according to the amount of carbonate present. (b) With an excess of carbonate the sulphite is apt to deteriorate with extraordinary rapidity in particular conditions that we have not yet been able to determine, and therefore cannot guard against. (c) If only a small amount of carbonate is present it changes into bicarbonate as the sulphite deteriorates, so that an accelerating agent is replaced by a feeble restrainer. (d) If an excess of carbonate is added to the sulphite caustic soda is ultimately found, which is a very likely cause of stain in the pyro-soda developer. These four facts seem to confirm our original observations founded on simple development tests, and they certainly tend to show that sulphite and carbonate are best kept separate. Details of further tests will be published later, together with the method of analysis, which has some points of interest.

## WHAT IS YOUR STANDPOINT?

"What men need is stand point, and there is nothing like a good talk for giving them that."—*Waldo Pondray Warren.*

your standpoint correct—logical? Do you apply it consistently along all lines in the conduct of your business? Are you careful in some things, careless in others? Do you gain or lose according to your care of the details that are for consistent standpoint—consistent business tact. As we see:—

Suppose you have an idea that your business permits conduct of philanthropic lines: that you can run it on a sort of voluntary institution basis, and contemplate with equanimity—even satisfaction—a state of affairs where all is outgo and nothing income, not even stopping to plug up the unnecessary leaks.

Suppose, again, that you have a very exalted notion of the value of your shop, but don't see that it is necessary to offer your superior goods in clean packages—*how long will it last?*

Suppose you stand pat on your knowledge that your work is good—better than good—and when you tell people about it you choose the very poorest, cheapest medium you can find—*will you make an impression?*

It often. People judge you by your dress as well as by your talk.

As a professional photographer, for instance, in his correspondence, is content with inferior stationery (or no stationery at all), how can he hope to impress those whom he must perforce reach by mail? It will not help matters much for him that his studio is full of excellent examples of his workmanship; the first impression he makes on his prospective clients is unfavourable he can hardly hope to have those clients view his work at first sight. People will judge him by the quality of his overtures, and if they are not up to the standard he sets in his own work, they will never be the wiser. It is a

mistaken economy that a first outlay for tasty stationery is a pure "expense" item—it is as much "mdse." as his chemicals and plates. It comes into the same category as raw material from which he fashions the output, since it largely incites the demand for that output. It comes under the head of necessities of the shop, just as do the rent and light bills, which he wouldn't dream of checking up against expense. It is even more necessary than either of these, since they can be—and will be—dispensed with if no business results. And good stationery—in keeping with his own standard of work—is consistent. It tells the world at large that his standpoint is up, not below par.

To do without this personal advertising medium is like buying a mine, and, after erecting a costly outfit of buildings and machinery, to sit by idly without digging into the ground for the metal. It is like exposing for a picture but never making a print from the negative. It is conducting a business along un-modern lines, for to-day the mails are fifty per cent. of the value of any business—because the cheapest in the long run.

And because the mails are the cheapest means of reaching the most people is just why the live photographer of to-day should take advantage of them in the way of good stationery medium, cards, announcements of exhibits, and invitations to his studio. Such advertising reaches nearer the recipient in that it has the personal note, which is lacking in a publication advertisement, although that form of reaching the public is necessary also, and in that it can be governed to suit exigencies. You can pick your people, have whom you want, and, if you make it exclusive, you will get the best—that is, the kind that pays best. You can make your studio the periodical rendezvous of a discriminating clientèle, and get results that will satisfy

your pride as an artist as well as pocket money; or you can make it a popular place where much business is the order of the day, with probably not so much satisfaction in doing good work, but equally remunerative. That is a choice your environment should dictate. But whatever it is, there should be kept in mind at all times the necessity of consistency—according to your standpoint.

There is no redundancy necessary in this form of advertisement. Only a consistent use of it and the mails, in keeping with your ideals, and it may be said without fear of contradiction that for its availability and usefulness there is no cheaper or better way to be had.

LOUIS F. FUCHS

\* The writer's remarks, with which we are in entire agreement, are quoted from our contemporary, the "St. Louis and Canadian Photographer."—Eds. "B. J."

## ACID AMIDOL DEVELOPERS.

WE have already recorded the fact that M. Balagny was awarded a medal by the Société Française for his method of developing transparencies with an acidified amidol developer. At a recent meeting of the above society he strongly recommended its use also for time exposures.

He pointed out that numerous formulæ had been proposed since his original one given first three years ago, but that they were all practically merely modifications of his, and that all of them had employed sodium bisulphite lye, notwithstanding the great outcry that had been raised that this would not keep. He had found, however, that a commercial solution had, without any particular precautions, kept for over twelve months and was as good at the end as the beginning.

His original formula was:

Amidol .....	6 gms.
Sodium sulphite (anhydrous) .....	12 gms.
Potassium bromide, 10 per cent. solution ...	30 ccs.
Sodium bisulphite lye .....	30 ccs.
Water .....	1,000 ccs.

This is specially useful for instantaneous work, and in special cases the bromide may be reduced to one-fifth of the above. As a rule, however, this formula is too energetic for time exposures.

MM. Lumière have given an excellent formula for this developer, but, like many others, it is far too energetic. This extreme energy is the reason why amidol is not used much by amateurs for negative work; and if it were possible to find a brake for it, amidol ought to replace all its predecessors as a developer. This brake, asserts M. Balagny, is to be found in an acid.

Tartaric, citric, and other acids were tried, but without success; they all of them decomposed the sulphite; finally, sodium bisulphite was thought of, and this was found far more satisfactory than reducing the quantity of sulphite, which was tried and found to be a failure.

For time exposures of all kinds, particularly those of subjects with heavy shadows, such as woodland scenes and interiors: the following method of making this developer is the best. In the first place, a stock solution of "bisulphite liquor" is made as follows:—In 125 ccs. of water dissolve 20 gms. of anhydrous

sodium sulphite, and add 75 ccs. of commercial solution sodium bisulphite. This solution contains exactly 1 gm. sulphite and 3.7 ccs. lye per 10 ccs. of solution. As soon as the solution is made, the suffocating odour of sulphurous acid disappears. It is not worth while to make more than 200 ccs. this.

For a time exposure the developer should be—

Amidol .....	3-6 gms.
Bisulphite liquor .....	48 ccs.
Ammonium bromide, 10 per cent. solution..	60 drops.
Water .....	1,000 ccs.

The negative should be flooded with this solution, and if the image has not appeared in from four to five minutes, 12 ccs. of the liquor should be added; further additions up to 90 ccs. all may be made if desired; in fact, one works exactly as though one were using pyro and carbonate of soda.

It will be seen that 3 to 6 gms. of amidol may be used; the reason of this is that if the dish is rocked the smaller quantity may be used, and this is the method preferred by the author, it gives great softness. If, on the other hand, the dish is rocked without rocking, then the larger quantity should be used. In certain cases and with certain plates, if insufficient amidol used mottling is caused.

For subjects with extreme contrasts, such as portraits outdoors in the sun, or harshly-lit interior portraits or woodland scenes, then the following should be used:—

Amidol .....	3 gms.
Bisulphite liquor.....	60 ccs.
Ammonium bromide, 10 per cent. solution..	120 drops.
Water .....	1,000 ccs.

The above quantity of bisulphite should be used to commence with, and the bromide may be even increased to 240 drops, according to the exposure.

The quantities of amidol and bromide may be varied at will, and for interior work small quantities can be used, and for outdoor work larger quantities.

The advantages of this developer are that there is nothing to calculate, and it is applicable to all classes of work.

MESSRS. L. GAUMONT AND Co. (formerly of 22 and 25, Cecil Court, Charing Cross Road) have removed to new and more commodious premises, at 5 and 6, Sherwood Street, Piccadilly Circus, London, W., where all communications should in future be addressed. The goods entrance is at 18, Denman Street, Shaftesbury Avenue.

CINEMATOGRAPE REALISM.—Realism in the making of cinematograph pictures led to a strange accident on the London and Brighton Railway, near Stoats Nest, last week. An enterprising firm of dealers in these wares were anxious to produce a trainwrecking scene, in which the wreck was to be averted by the intelligence of a railway dog. The firm's employees, properly made up to represent villains of the piece, were to lay a sleeper on the line, seize the signalman (impersonated by a man named William Zeitz, of Croydon), and bind him to the line near the sleeper. Then the faithful dog was to arrive, find his master bound, fetch the wife, who was to place

the signal at "danger," and the train would dramatically pull up safely. Everything worked like a charm—up to a certain point. The "villains" entered on the scene, laid the sleeper, and bound the man. Then the faithful dog arrived with his master's dinner, found him in bonds, and fetched the dutiful and loving wife. Unfortunately, the scheme went wrong at this point, and the train, instead of making its dramatic stop, charged the sleeper and knocked on to the bound man, who received a scalp wound and had several ribs broken. Inquiries show that the scene in which Zeitz received his fatal injuries was carried out in violation of the rules of the Brighton Railway Company, and it is stated that the officials of the company are so incensed at "the most unheard-of liberty" that they have suspended the engine-driver and his fireman. The party station-master took in the proceedings—how far they were sanctioned by him—has been the subject of inquiry.

# THE ISOSTIGMAR LENS AND THE PETZVAL CONDITION.

The following is a paper read before the Royal Photographic Society on March 12, under its full title of "The Isostigmat Lens: a new anastigmat lens that does not fulfil the Petzval condition." The report of the paper, which appeared in our issue of March 15, has shown the interest of the question raised by the Messrs. Beck as to the value of the Petzval condition as a guide to opticians. The remarkable properties of the new lens have been obtained whilst disregarding the Petzval condition.—Eps. "B.J."]

A description of a new type of photographic lens must be of necessity somewhat of the nature of the technical description of a logical specimen, and is not interesting unless some new principle involved in its design.

We hope to show, however, that the Isostigmat is something more than a new species of the genus anastigmat, and is a departure from the ordinary type, because it demonstrates that one of the hitherto accepted theories of geometric optics under certain circumstances is either wrong, or at any rate, only partially correct.

It has been asserted, and a proof has been advanced by Coddington, Petzval, and most later writers, that a certain condition, hitherto known as the Petzval condition, must be fulfilled in order to produce lenses which will give a flat field free from astigmatism. You will remember that this condition, which has been shown by Sir William Bragg to have been first discovered by Coddington, states that for lenses to be anastigmatic, and at the same time to give a flat field, it is necessary for the sum of the focal powers of its individual lenses multiplied by the reciprocals of their respective refractive indices, to

be equal to zero. That is  $\sum \frac{1}{\mu f} = 0$ , and it also shows that when this is not equal to 0, the amount that it is equal to, is the reciprocal of the radius of curvature of the field.

## Applications of the Petzval Condition.

Different methods of making this equation equal zero, and, thus producing anastigmat lenses, have been described in various patents, and it will be within your recollection that a paper was read at your Society by one of the present authors in June, 1904, describing the original and ingenious method by which the Petzval condition had been satisfied by Dr. Rudolf Steinheil, of Munich. We do not doubt

that the construction of a lens in which  $\sum \frac{1}{\mu f} = 0$  is one method of

producing anastigmat lenses, but the Isostigmat lens which we are going to bring to your notice this evening demonstrates that it is not the only method. This lens has been 'worked' out on certain lines, which do not take the Petzval condition into consideration, and another method of obtaining a satisfactory lens was arrived at. The work worked itself down to the gradual process of correcting along various lines which developed the somewhat unusual form of a 5-lens

inch. The radius of curvature of the image which is free from astigmatism should therefore be 25 inches. This would mean that at an angle of 35 degrees the image would be about .48 inches away from the plate, whereas, as a matter of fact, it is not so much as 1-50th, whilst the greatest distance of the image from a flat plane at any angle is less than .09 of an inch. In Fig. 2 the actual curvature of the image is shown in solid lines, while the dotted line represents the shape of the field according to the Petzval condition. You will see that the only want of flatness of field in this lens is the slightly convex zone between 18 and 26 degrees.

Fig. 2.

## A Possible Cause of the Inapplicability of the Petzval Condition.

Von Seidel has shown that the Petzval condition only holds good when the lens is correct for central spherical aberration and for coma, but these two corrections are certainly made to a very high degree of accuracy in the Isostigmat lens. Dennis Taylor has pointed out that when separated lenses of equal but opposite focal lengths are used, the resultant power being obtained by separation, the radius of curvature of the field may be made so large that the image is not very far from flat. But the length of the radius of curvature from the data given in his book does not appear to us to account satisfactorily for the degree of flatness of field found in practice in the Cooke lenses made on his method.

The proof of the Petzval condition given by Coddington is worked out by means of a formula, which is in the form of cosines of angles. In order to eliminate these unmanageable quantities they are expanded, all but the first two terms of the series being neglected. Again, in the terms which represent the inclination of the bundles of incident and emergent rays to the axis, approximations are also made, functions in terms of the second order being put into the first approximation. Previous writers have assumed that these approximations were sufficiently accurate, but it may be that the terms of a higher order than the second in the formulae have a very large effect on this particular condition, and may in some cases largely increase, and in other cases largely reduce, the resultant curvature of the image.

From a careful examination of the proof of the Petzval condition the above points appear to show the directions where error can arise. That the Petzval condition is not universally true is evident; how far it is true, and whether the actual condition that determines the whole problem is one that is capable of being simply expressed, is, in our opinion, somewhat doubtful, but as we have not the time at our disposal to work out this interesting question, we are anxious to bring the matter before the notice of English mathematicians.

It may be interesting for you to observe practically the absence of astigmatism in this lens by projecting upon the screen the image formed by it of a grating. The grating is placed in a collimator in such a way as to appear at an infinite distance, and an image is formed by the lens in the plane that would generally be occupied by the photographic plate. Instead of placing a ground glass to receive this image we project it on to a screen on an enlarged scale by means of an ordinary projecting lens. The Isostigmat lens is then swung round to various angles, and the portion that would be occupied by the photographic plate in the camera is automatically kept in focus upon the screen. In this way any errors of the lens are largely exaggerated in the image. As our lens testing bench is the most satisfactory method that we have of doing this we have brought one up here

Fig. 1.

## Discrepancy Between Theory and Practice.

There seems to be some confusion amongst the various authors who have written on the Petzval condition as to whether the focal length should be the equivalent focal length of the individual lenses or whether it should not be what is sometimes called the pseudo focal length—that is to say, the focal length of the lenses neglecting their thickness. This makes a considerable difference in the result, but the Isostigmat lens more nearly fulfils the Petzval condition when individual lenses are treated as being infinitely thin, we will investigate it on these lines. In this lens thus treated, the expres-

sion  $\sum \frac{1}{\mu f}$  is not zero, but is about a quarter of the complete focal power of the whole lens—that is to say, in a 7½-inch lens  $\sum \frac{1}{\mu f} = 0.4$

for the purpose. By this means you have an ocular demonstration of the fact that the astigmatism is well corrected over the whole of the field of 70 degrees. This proves that the lens is anastigmatically corrected and that the field is practically flat. The question as to

the accuracy of our statements regarding the  $\frac{1}{\mu f}$  are not so readily

demonstrated, but any one who is interested in the subject can easily check these by working them out, the necessary data being given in our patent. For comparison with this we will now show you the same grating shown by a rectilinear lens under exactly similar conditions. You now notice that a considerable amount of astigmatism exists, the projecting lens having to be moved either backward or forward so as to focus the different lines sharply upon the screen; the best position for general sharpness being between the two foci.

In a subject of such complexity as the construction of lenses, it is not to be wondered at that a broad conclusion, such as the Petzval condition, is not universally true. A great deal more work requires to be done before geometrical optics will become as exact a science as pure mathematics, and whilst in no sense detracting from the gratitude which we feel for these investigators who have already laid down the groundwork of the fabric, it is advisable to approach any problems that may arise with an open and sceptical mind. It seems to us that there are other important conditions governing the problems of optical corrections which have not yet been discovered.

### Oblique Spherical Aberrations.

Another quality in our lens is the excellent correction of the oblique spherical aberrations. So much attention is bestowed upon the astigmatism of the marginal rays that it is sometimes forgotten that this is only one of the errors to be corrected. A lens may be free from astigmatism but may have considerable oblique spherical aberration, and may also have coma, or unsymmetrical oblique refraction. If these errors are large, they may neutralise to a considerable extent the advantages of an anastigmat lens. In order to demonstrate this matter more fully we have prepared the slide, Fig. 3\*, now shown, upon the screen. This consists of a series of very greatly magnified views of a minute disc of light as it appears on different portions of the plate. The disc of light has been carefully focussed on to the centre of the plate and then photographed by means of a microscope and camera. The disc of light as seen at a distance of 5 degrees from the centre of the plate is then photographed and placed by its side; the same is done at every five degrees up to 30 degrees, and then at 32½ degrees and 35 degrees, except in the case of lenses which do not admit such a large angle. The row of spots at the top are the very much enlarged view of these discs taken with an Isostigmat lens. The ten series below are discs magnified to exactly the same scale, photographed with various anastigmats made by ourselves and others, and include all the best known makes of lenses which have apertures of between  $f/5.6$  and  $f/8$ . We do not put any names against them, as we do not wish to make comparisons. Such comparisons, we consider, should be made by impartial observers, but we wish to draw your attention to the great differences that exist between different types of anastigmat lenses. The bottom series shown are taken by a rectilinear lens, and are put in for comparison with the others. All the diagrams are reduced to an exactly similar scale for the purpose of comparison.

### And Their Effect on Depth of Focus.

It is interesting to note, in looking at this diagram, that even in the centre of the plate there is very considerable difference in the size of the photograph of the disc of light, given by different makes of lenses. This is due to the fact that in some the central corrections are far from being completely satisfied. This is a matter of great importance in lenses which are to be used for telephotography. But perhaps the most important bearing on the practical value of a lens that is afforded by this comparative diagram is with reference to depth of focus. It is thoroughly well known that the depth of focus of a good lens in the centre of the field cannot be influenced by the

optician; it depends only on focal length and aperture; but the depth of focus at the edge of the field depends also upon the oblique corrections. Where the image of a point of light at the edge of the field is still a point, the full depth of focus is obtained over the whole field; but in some of the diagrams shown it is a considerable amount, and in such lenses the only chance of getting a sharp picture have the object almost exactly in focus, and the depth of focus at the edge of the field is reduced to a vanishing quantity when the oblique aberrations are badly corrected.

### A System of Lower-power Components.

The correction of a photographic lens is a difficult matter, because there are so many errors that must be simultaneously overcome, and it has always been our opinion that the principle of making use of individual lenses which have as long focus as possible, and therefore small errors, was one which had advantages over the method of using lenses of high power, and large initial errors neutralised by other

Fig. 3.

lenses of high power and opposite errors. Mr. Dennis Taylor, his Cooke lens, made use of this principle in the oblique correction. Dr. Steinheil, in his Unofocal lens, used comparatively low-power lenses, but to fulfil the Petzval condition with cemented combination requires very powerful individual lenses, with large initial error. In our departure from the Petzval condition we have been able to use lenses of very low power, and thus reduce the initial errors which have to be corrected. In fact, no individual component has shorter focal length than one-half of that of the complete objective.

It may now be of interest to describe some of the more important aberrations which have to be corrected to make a high-class lens.

### Two Orders of Aberrations.

If we first look at a simple uncorrected lens which brings parallel light to a focus, we find that it has considerable aberrations even when the object examined is upon the axis of the lens. Now these aberrations can be classified under two main headings, namely, those which occur near the focal point, and those which occur near the lens. We can make this matter clearer by means of a diagram, Fig. 4a. If we consider a lens of two or more refracting surfaces we know that the equivalent focus of the lens for a given ray should be measured from the point B, Fig. 4a, where this ray cuts the axis to the point A, which is the point where the plane AC cuts the axis C, being the point where the emergent ray continued backward

\* The various small photographs which comprise this diagram were covered with a mask with apertures and re-photographed. The edges of these apertures must not be confused with the images of the disc of light.

the line of the incident ray. That is to say, the equivalent focus of the ray in the top diagram, Fig. 4, is AB. Now, if we consider the second figure on the diagram, Fig. 4β, we see that for the two rays marked C, which are supposed to be very near the centre of the lens, the distance AB is the equivalent focus, whilst for the rays near the edge of the lens, the distance DH is the equivalent focus. This lens, therefore, there is an aberration HB at the focal point, and an aberration AD at the end nearest the lens. Now it is possible to make a combination of lenses, one of which is shown in Fig. 4γ, in which the error at the focal end is completely

corrected, but such a lens would not give correct images over a very large angle of field. In order to do this it is essential that the equivalent planes should be perfectly flat, which is what is known as the tangent condition; but for the lens openings which are used in photography, except for the very largest apertures, the difference between the sine and tangent condition is so small that, provided the lens is corrected for either one or the other, it may be considered as being aplanatic.

Therefore a perfect photographic lens must bring the whole bundle of light to an exact focus; the rays CC and EE, Fig. 4 (β), must all

Fig. 4.

corrected, whilst the error at the lens end, or which we may call the error in the equivalent points is very great. On the other hand, it is possible to make a combination of lenses, such as shown in Fig. 4β, in which the error at the equivalent point is very small, whilst the error at the focal point is very great. In order for a lens to be perfectly aplanatic it is not only necessary for it to bring down every ray to the focal point, but also for the focus of the equivalent points of the individual rays to form a spherical surface, of which the centre is the focal point. A lens which does this fulfils the sine

condition, and the focal aberrations will be corrected. The equivalent planes A and D must also be superimposed and the equivalent plane will be corrected. The focal corrections in the centre of the field in a lens with so many surfaces as the Isostigmat can be made in many ways, allowing great scope for selecting the most suitable form to make the other corrections.

CONRAD BECK.

(To be continued.)

## PICTORIAL FOCUS IN PORTRAITURE.

In a recent issue appeared an inquiry regarding the method of producing portraits in which the head of the sitter is fully lighted, while the drapery is kept in quiet repose. The matter may well be considered in detail, and several methods of producing the effect, all of them quite practical, may be indicated. The main idea, of course, is to emphasise the face by subordinating all the rest of the picture, and the appreciation of the effect produced is an indication of the upward kind of middle-class professional portraiture. A portrait is primarily a picture of a face with characteristic or individualised expression, and though accessories in the shape of furniture, draperies, and so on are necessary, they must be kept in a position

of secondary importance, and not allowed to clamour for equal attention with the face. Attention is thus focussed on the important portion of the picture by reason of the greater contrasts, and in some cases also by reason of the sharper definition, though definition need not be further referred to in the present article. This relatively small area of supreme interest is often termed the "pictorial focus" of the picture, and should be present in all good work.

### Lighting to Obtain the Effect.

Undoubtedly the best method of obtaining the effect is by proper lighting of the subject. "As the sitter's lighted, so's the picture

drawn," and if the operator can see the effect he is aiming at he may be pretty sure the final print will show it also, granted good technique in the shape of proper exposure and development, suitable to the printing process decided upon. The customary flood of light over the whole of the subject naturally gives equal prominence to everything. We see at once, therefore, that the flood of light is just what must be avoided. Many workers when building or altering a studio insist on the side light going down to within a foot or so of the floor, "in order to get plenty of light on the feet." As a rule, too much light reaches the feet, even when the side light is much more than a foot from the floor. But assuming that the best must be made of the studio as it at present exists, the first step should be to cut down the area of top and side light by drawing down the opaque blinds until the open area is from 6 feet to 8 feet square, according to the nearness of the glass to the sitter. The smaller the studio the smaller may be the area of open skylight. The amount indicated will be sufficient for any half length, three-quarter, or full-length portrait. If this area of light-admitting roof is a little above, a little to the side, and a little in front of the sitter, it will be found that the highest light on the face will be in just the right position on the forehead, and that the head will be more brightly lighted than the rest of the figure. But this differentiation is insufficient for our purpose, and if the light is still further narrowed down the modelling of the face will usually become very forced, the shadows too solid, and high lights too brilliant. What is needed, therefore, is to throw a shadow over those parts of the subject which are to be kept in repose, and this is undoubtedly best accomplished by the use of secondary blinds, which may be placed nearer to the sitter. A large side screen (which for experimental purposes may be constructed from a background stretcher, mounted on the usual triangular castored stands, the background, of course, being detached), is placed between the light and the sitter. If the screen is 9ft. high it may be divided into three transverse sections, by means of tightly stretched wires, each wire carrying curtains made of some light material, preferably of a grey colour. Pink is often suggested, but the disadvantage of such a shade is that the visual and photographic effects are likely to be dissimilar, whereas with a neutral shade like grey one can see how the plate will be affected. The upper grey curtains may be so arranged as to allow the full light from the skylight to fall on the head and shoulders, the lower curtains being drawn to shade the figure. A further refinement would be to have two sets of curtains, one of paler grey than the other, so that where the local colour was dark—for example, a red or black dress—very little light might be cut off, while with light draperies a good deal more might be kept back. For head and shoulder portraits much may be done by the use of a simple opaque head screen, placed so as to throw a shadow on the bust, and yet to be just out of the picture.

### The Effect of Development.

Some workers prefer to get the effect by local development of the plate. Any average developing solution is employed, taking care that it is so compounded as to give full detail during the earlier stages of development. This developer is poured over the plate, and as soon as the whole of the image is well up the plate is washed under the tap, and development continued locally with a pledget of cotton wool, the developer being applied to those parts where emphasis is required. Of course, all things are possible to the person who, with skill and patience, desires to demonstrate some special method, but the objections to this development method from

the practical everyday standpoint, are that working in the dark room and on the partially developed negative it is exceedingly difficult and sometimes impossible, to estimate the progress of the local development, in relation to the general development. Thus an arm or hand may finally come to light, or too dark and dirty-looking. Further, such a method naturally demands the separate development of negatives, a much more expensive method of working—from the time point of view—than development in batches. On the whole, the development method is the one, which has least to recommend it.

### Local Reduction of the Negative.

Safer, on account of the operation being performed in full day light, is the method of locally reducing those portions of the negative which it is desired to keep quiet in tone. If the negative is of average printing quality the persulphate of ammonia reduced will be the one to employ, as the tendency is to reduce contrasts as well as to slightly reduce the whole of the deposits. Here, again, the amount of time required for the work must be considerable, if any thing like due consideration and care are given to it, and such work is better left undone if not done with care.

### Frictional Reduction.

The method by frictional reduction has this to recommend it, that any light patches, such as lighter portions of a dress, may receive more localised treatment, and so be much subdued. Either methylated spirit, applied with a piece of clean, dry wash-leather and considerable friction, or the Baskett's globe polish and terebenthine reducer, or dry powdered pumice may be used, according to the preference of the worker. The results depend more on him than on the special medium selected. Great care is needed to avoid irregular workings, and for general areas the larger the wash-leather, pad, or cloth used for applying the Baskett's mixture the better.

### Sunning Down the Print.

In one way this is the simplest of all the methods. The print is finished, printing in the usual way, and then shading the face and upper half, the margins are darkened down by exposure to light, turning the print round so that each edge in turn is subjected to light action. With platinum and carbon prints there is some danger of carrying the "sunning down" too far, or not far enough, though by means of a strip of P.O.P., held in the light at the same time, it is easy, with a little practice, to hit the mark. It should be noted that with some papers the colour of the image formed by light varies with the speed at which that image is produced, and that a tint formed through clear glass will often be of quite a different shade to the actual negative-printed image.

### Importance of the Background.

Finally, a word may be said as to the importance of the background in pictures of the kind referred to. It is of no use subduing the draperies and figure generally if the background attracts as much attention as the face. Generally speaking, there should be some gradation in that part which comes against the head, and the ground should be neither too dark nor too light. The degree of contrast between the face and the background will naturally determine the contrast required between the face and the rest of the figure. It must always be remembered that dirtiness or muddiness of the accessories and draperies is not what is wanted, and if tone relationship is palpably false this is the effect which will be produced.

C. H. HEWITT.

**THE LANTERN IN COLONIAL INSTRUCTION.**—As a result of a Committee on Visual Instruction, appointed by Mr. Chamberlain in 1902, to consider the possibility of providing illustrated lectures for use in the schools of the Empire, the Princess of Wales has secured within the past few weeks a fund of £4,000 for the furtherance of the scheme. A lantern lecture on the United Kingdom has been made the subject of a test experiment, and has been circulated in Ceylon, the Straits Settlements, and in Hong Kong, and as a result other colonies have been supplied with lectures on the United Kingdom. The Committee are now anxious to take up the other side of their scheme and to arrange lectures on the Colonies for use in the schools of the United Kingdom. They had desired to secure

a sum of at least £3,000 to cover, among other expenses, the cost of sending a highly-skilled photographer to visit the self-governing Colonies, India, and all and each of the Crown Colonies and Protectorates, in order to take views and illustrations such as the nature of the work demands. When prepared, the slides and lectures will be on sale to educational authorities and the public. The Princess of Wales has enabled them to go on with the work.

C. BALDWIN AND CO., LTD.—Capital £6,000, in £1 shares. Objects: To carry on the business of chemists, druggists, dentists, opticians, manufacturers of and dealers in salts, photographic materials, and optical, scientific, and other instruments, etc. No initial public issue. Registered office, 77, Walworth Road, S.E.

# WAYSIDE NOTES.

It is that a different spirit seems to prevail in America? We are told that the worship of the dollar is all prevalent there, that competition is keener and more ruthless than in this country, yet the feelings of the Americans, reported from time to time in the "B.J.," seem to denote that among the photographers a better feeling exists in this country. At the convention in New York of the photographers of that state, several of the leading men in the city demonstrated their methods to the visitors, in the same way, for instance, Mr. Langfrier might have a party of onlookers in his studio on the night of a court presentation, or the Messrs. Speaight demonstrated their methods of making their famous little child studies.

The American photographer believes that he learns something at these conventions, and he is not above admitting it to his public when he returns to his own town, as witness this advertisement, which is clipped from an American newspaper.

## PHOTOS FOR CHRISTMAS.

It is high time that those who contemplate having photographs taken for the holiday season, arrange for sittings, and thus avoid the rush that always prevails at this well-known studio for several weeks previous to Christmas.

J. R. Hallam has just returned from St. Louis, where he attended the National Convention of Photographers, at which he was one of the exhibitors. During the convention he came in touch with many new ideas in photography, which he will incorporate in his work during the coming season.

## HALLAM THE PHOTOGRAPHER,

48 N. Main St.,  
Bell 'Phone 21-R.  
Washington, Pa.

Appropos of American methods, photographers in the North of England are having an example of what is being done on the other side of the Atlantic in the form of the Aristotype exhibition, which is being held in various northern towns this spring. Large rooms are engaged in one of the leading hotels in each city visited, and they are fitted up in such a way as to make a visit to them a matter of genuine interest, and possibly of instruction, to the professional. The Aristotype demonstrators I have met seem to be thoroughly practical men—men who can give reasons for their product being better than its price in comparison with that of competitive work.

Among the specimens shown two features especially attracted my attention. One was the novel mounting scheme of a number of warm-toned prints, about 15 x 12 in size, prints which ninety-nine times out of a hundred would be put on white mounts. These were mounted on a board of such a deep buff colour as to be practically a yellowish-brown, and with a surface of a linen-like texture. Surrounding the prints there were, in some cases, one, and in others two, borders of a medium or dark brown. Attractive in itself, such a scheme gives an additional advantage from its novelty. Amateurs have for some time now been more daring in the matter of mounting than we professionals; possibly the Aristotype exhibitions will serve to show that ordinary professional work looks equally well when mounted on these lines.

The other feature that I thought noteworthy was what my informant called the "white panel." This consisted of a number of prints, partly in collodion chloride and partly in platinum, headed shoulders only, and with the busts vignettted in an irregular manner; for instance, in a profile, the part of the bust in line with the features would be from two to three times as long as that at the shoulder. The prints had the appearance of the negatives having been very carefully blocked; anyway, the background was a dead

white, and then a very sketchy background had been delicately worked in with the aerograph. The working was slight, practically only enough to balance the studied careless appearance of the uneven bust line. I know the "sketch" carbon, or "parfait," as it is sometimes termed, has been shown for some years, but in the prints in question the air-brushed background is so slight as to make them, to all intents and purposes, a novelty. They are, of course, mounted with the print trimmed flush with the mount. Studios in which the dark backgrounds have been run for some time would, I feel convinced, benefit by a change to this style.

Despite the fact that the committee of the P.P.A. report an evidence of increasing interest in the Association during the last year, the present state of that body is a reproach to the profession. Out of a number of something like 8,000 photographers in the United Kingdom only 524 show sufficient pride in their means of livelihood to join an association for promoting their common interests. Meeting, as I do, many photographers I frequently put the question, "Why are you not a member of the P.P.A.?" and the answer is, nineteen times out of twenty, either "What's the use?" or "What should I get out of it?"

There is, it will be seen, some difference in the two replies, and they fairly well indicate the class of man making them. To the first I point out that the public very largely forms its first impression by the estimate that a man sets on himself, and therefore if the photographer shows that he thinks sufficiently well of his profession to consider association with other members thereof desirable, such an association will, if well supported, in a very short time command the respect of the public, a respect in which he himself will share. If the accountants did not value their charter themselves, is it likely that the public would set the store they do by the term chartered accountant?

The other question, coming from a different type of man, calls for another reply, and I generally put it that the small subscription is really but a form of insurance. He may get involved in a copyright dispute, and, if he be in the right, the support of the Association will very likely secure an immediate settlement without recourse to litigation; while, if in the wrong, the advice that he will be given will prevent him incurring any expense in obtaining legal advice. I tell him that his fellow professionals, who are at the top of the tree, men who certainly do not stand to "get anything out of it," are sufficiently interested in the welfare of their profession to sit on a committee, discussing his troubles and giving him the benefit of their experience. And, finally, I tell him what the Hull photographers, led by the redoubtable T. C. Turner, did in the matter of the Oxo enlargement scheme. But it's weary talking to such men!

The other night at "The Playhouse," the charming little theatre that has been rebuilt on the site of the old Avenue Theatre, destroyed by the collapse of the S.E.R. Charing Cross Station roof, I chanced to overhear a remark which I thought would interest a good many photographers. A lady was looking at her programme, and said, "How artistic! I do like this cover; it's enough to make one say the piece is good without seeing it." The cover, as a matter of fact, was designed for the theatre itself, and had no particular reference to the play in question, since the title line at the bottom could obviously be changed for whatever play happened to be running.

The moral I mentally drew from the remark was that any piece of advertising, the manner of the receptionist, or the state of the reception-room, would probably affect that lady in the same way were she to go to a photographer. She would judge the photographer by his surroundings, and the idea that she was going to have a satisfactory photograph taken would be more than half way to ensuring that the final result would be such. And, I believe, there are many people in this world who are similarly influenced.

THE MAN ON THE ROAD.

## AN EXPERIMENTAL COATING MACHINE.

For experimental purposes a machine that will coat evenly and well paper of the normal width of about 26 inches and in reasonable lengths is a great desideratum. The only machine now on the market is one constructed by Schippang, according to the designs of Herr Zink, of Gotha. This, however, as pointed out by Herr Th. Bentzen, in "Die Photographische Industrie," is only designed for five-metre lengths, in which length it is extremely difficult to ensure perfect regularity of movement. Also one frequently wishes to test a greater lengths. Another point is that with the repeated use of five-metre lengths there is always waste of paper and emulsion at the beginning and end of the lengths.

The above-mentioned machine is satisfactory for collodion paper, for which it is specially designed, but not for gelatine emulsions. Coating of small pieces of paper with gelatino-bromide and gelatino-bromide emulsions with coating frames is very unsatisfactory. Not

the roll *A* over the roller *b*, round the dipping or coating roller *c*, through the emulsion trough *d*, then over the roller *e* on to the setting table. One part of the setting table consists of a sheet of plate glass *i*, which is shown in the diagram slightly below its proper level, in order to make it quite clear. Over this sheet of glass runs an endless cloth (canvas), *f*, over the rollers *g* and *h*, whilst a second endless cloth *n* is stretched over the rollers *o* and *p*. These rollers *o* and *p* are regulated by adjustable screw arrangements, which are not shown in the sketch, so that the three triangular wooden rods, *k*, *l*, and *m*, which are glued to the cloth *n*, and are separated from one another by the length of the sheets of paper, press the paper against the cloth *f* and the glass plate underneath it. The rollers *g* and *h* are lengthened somewhat and provided with a groove in which a crossed leather belt is stretched.

If now the fly-wheel *r* is turned by the handle *s* by hand, the

only is it wasteful, both of paper and emulsion, but regularity of coating is difficult, and it does not pay the small user who wishes to coat his own paper.

Some years ago the author has had to calculate the cost of certain papers, and was forced to devise a machine which would do the required work in sufficient lengths. He constructed a machine which has proved to be perfectly satisfactory for experimental work, although unsuitable for large turnover. This last fact is accounted for by the fact that although the paper can be coated in the roll, yet it is not sufficiently long to be sold as such, but only in sheets, and also because the size marked during the preparation slightly alters in consequence of the extension of the cloth—a defect very difficult to avoid.

The accompanying diagram explains the construction of this experimental coating machine. The baryta paper *a* is drawn from

paper will travel forward, and can be taken up by rods, after it has left the machine, and these can be supported on two parallel bars and looped up to dry. If the room is too short the parallel bars can be bent round and thus a second track produced; this can be repeated as often as the width of the room will permit. In an ordinary room it is easy to coat and hang up 100 metres of paper.

Below the glass plate *i* an ice box can be easily placed for making gelatino-chloride papers; for collodio-chloride paper the room must naturally be heated.

As the necessary slow revolution of the fly-wheel is difficult to attain, particularly with those not used to it, it is advisable not to fit the fly-wheel direct on to the roller *g*, as shown in the sketch, but to arrange it further between *g* and *h*, and then to regulate the movement by pulleys and straps, so that a quick and regular revolution of the fly-wheel is converted into a slower movement.

## KALLITYPE FOR WINTER LANDSCAPES.

THE Kallitype process, the details of which have from time to time appeared in our columns, is the subject of warm encomiums in the current issue of the "Photo-Era," where it is particularly commended for the printing of negatives of winter landscapes. The following is the text of the communication:—

The progressive amateur who practises photography from pure love of it is usually a true artist at heart, and, as such, he will, sooner or later, chafe at the restrictions imposed upon him by the printing papers on the market—the necessity of employing different processes to obtain the best results from different negatives, or the monotony consequent upon using the same kind of paper continually, even if it were possible to obtain results otherwise satisfactory thereby.

To such workers as earnestly strive to produce real pictures, and are willing to devote a little labour and patience to that end, the kallitype process offers such advantages that it should lastingly appeal to them. Its preparation and manipulation are easily within

the ability of the ordinary careful amateur, and by variations in the quality and character of the paper used, the same negative may yield prints so different in texture, gradation, and tone, as to be a source of constant wonder and delight to the operator.

The process is not limited to a certain class of negatives either, as slight variations in the proportions of the sensitising solutions adapt the paper equally to negatives of thin and soft, or hard and contrasty variety, while the finished prints will compare, in artistic beauty, to platinum at its best. Added to these decided advantages is one more—the process is inexpensive.

### Papers for Kallitype.

The paper itself is the most important factor in the result obtained. The specially prepared photographic papers, such as Steinbach, yield soft tones, with a tendency to cold black. Whatman's water-colour paper, easily obtained in all surfaces, from smooth to very rough,

ers a wide range in results—the rougher the surface the greater the tendency toward broad, sketchy effects, and warmer tones. Beautiful results may be obtained by the use of architect's drawing-paper, known as "egg-shell"; it is heavy and strong, and yields rich brown tones. Ordinary ledger-papers, such as Weston's or Scotch linen, are very useful in this process, and are more used than any other kind. The soft Japanese papers yield prints which are the refinement of artistic elegance, but require more care in the preparation and drying, it being necessary to mount them with white dextrine, on strong, white paper, such as ledger or Bristol board, before the sensitising process, and allowing them to remain on this supporting printing and development; if the paper does not leave its mount during the latter process it may be removed easily by immersing in warm water.

#### Sizing with Arrowroot.

Japanese papers require negatives of rather strong contrasts to get the best results. It is absolutely necessary that the Steinbach or Whatman papers be "sized" to keep the sensitising solution on the surface. While the other papers mentioned above can be used without sizing, the prints are so much improved by the process that the little additional trouble is well spent.

Arrowroot is especially recommended, as it not only fills the pores of the paper, but it leaves a soft deposit which renders rich half-tones velvety-blacks. To prepare such size, rub eighty grains of arrowroot flour into a stiff paste with a little cold water. Add to this, stirring constantly, sixteen ounces of hot water, and bring the solution to a boil. Now add four ounces of alcohol, stirring constantly, in through muslin, and immerse the paper for about two minutes; then hang up to dry. Repeat this operation, hanging the paper from stronger ends, and, when thoroughly dry, it is ready for the sensitising solution. This is made up in four stock solutions, kept in glass bottles, in a dark, cool place.

#### The Sensitising Formula.

I know of no improvement over Mr. Henry Hall's formula, which is as follows:—

Solution A.—Distilled water, 5 ozs.; ferric oxalate, 1 oz. Reverse for 24 hours, and put away for 24 hours; then add 48 grs. selected arabic.

Solution B.—Distilled water, 8 ozs.; ferric oxalate and potassium, ½ oz.

Solution C.—Distilled water, 4 ozs.; oxalic acid, ½ oz. When this is dissolved, bring to a temperature of 75 or 80 degrees, and add 100 minims stronger ammonia water; then filter.

Solution D.—Distilled water, 4 ozs.; bichromate of potassium, 1 gr.

For normal negatives, use Solution A, 1 oz.; Solution B, ½ oz.; Solution C, 30 minims; Solution D, 4 drops. Of the above, take 12 and add 12 grs. nitrate of silver, stirring with a glass rod until dissolved.

For harsh, contrasty negatives, use of Solution A, 1 oz.; Solution B, 1 oz.; Solution C, 35 minims.

For soft, thin negatives, use of Solution A, 1 oz.; Solution B, ½ oz.; Solution C, 15 minims; Solution D, 8 drops.

In preparing solution for contrasty negatives, use 14 grs. of silver instead of 12. Apply to the paper by pouring a small pool of solution in the centre, and distributing with a two or three-inch camel's-hair brush bound in rubber, using no more than sufficient to cover the surface of the paper thoroughly. This operation is conducted by lamplight, and when the paper is surface-dry it is hung over a stove or placed in an oven, so that it may quickly become bone-dry. Print until outlines are fairly visible, and proceed with development.

#### Developers for Black Tones.

Developer Formula—Stock Solution.—Distilled water, 32 ozs.; acetate of soda, 4½ ozs. Of this take 8 ozs.; add tartaric acid, 12 grs.; Solution D, 20 minims.

If this does not yield tones sufficiently black, add 25 to 50 minims of 50 per cent. phosphoric acid. After thorough development, rinse, and clear for half an hour in a fresh bath composed of distilled water, 8 ozs.; sodium citrate, ½ oz.; citric acid, 20 grs. Wash thoroughly and finally fix for ten minutes in a bath composed of water, 16 ozs.; hypo, 7 drams; stronger ammonia, 90 minims. Wash thoroughly and dry. Of course, a good negative is the greatest help to a good print, and should be striven for in the first place.

In photographing landscapes covered with snow, my experience has led me to the invariable use of non-halation orthochromatic plates, with a normal yellow screen. This is because of the presence of so much blue tone in the shadows and broken parts of the snow surface, which, if not corrected, would fail to give sufficient contrast to the unbroken white of the snow. I generally use Stop 16, giving full exposure, followed by full development. If the high-lights are too dense I reduce them with persulphate of ammonia, which leaves the shadows practically untouched.

A rough-surface Whatman paper is very effective for this class of pictures, giving a wash-drawing effect, and breaking up what might be a too flat expanse of white. Rough papers also aid in securing diffusion and atmosphere. Irrespective of the paper used, I frequently employ one or more sheets of celluloid interposed between negative and paper. This produces sufficient diffusion, without forcing some portion of the picture too much out of focus, and suppresses detail which might be too insistent.

In making prints on Japanese papers, if considerable margin is allowed, and a mask used on the outside of the negative, instead of between it and the paper, a soft outline is obtained, and the finished print, especially if a warm tone is being produced, resembles in appearance an artist's proof of an etching or mezzotint-engraving. These papers should be dried between clean blotters and under pressure.

There is no greater pleasure connected with the art than to watch the development of a beautiful print on home-made paper and to realise the immense possibilities and control which lie under the hand of the worker.

JAMES S. ESCOTT.

## THE SPECTRUM AND THREE-COLOUR PHOTOGRAPHY.

(From "Das Atelier des Photographen.")

When a spectrum of small dispersion is observed, the impression is as though it consisted of only three colours. Reddish, green, and blue-violet take up very large portions, whilst yellow and blue-green are limited to narrow sections. The individual colours thus possess a very different extension, and the transition from red to violet, the so-called crimson, is completely wanting in the spectrum. This distribution of colours is shown in I. Fig. 1.

Obviously these facts are due to the physiology of our eyes. They are excited to the sensation of "crimson" by one set of rays, the numerous homogeneous rays cause the sensations red, green, blue.

Between the objective light vibrations and the colour sensations

of our visual apparatus there is, therefore, considerable incongruence, for if the colour sensations changed proportionately with the increase in wave-length, the spectrum must show a distribution of colours, as shown in II. Fig. 1.

From the physiological standpoint, therefore, one may also say, that white light contains no purplish red, and only small quantities of yellow and blue-green rays; it consists essentially of the components red, green, and blue.

In the world of colour round us, however, all colours play an equally important rôle, as yellow, for instance, occurs in nature as often as green and red, and since the colours of all substances can be traced back to absorption phenomena and are thus formed from white

light, so the material colours can only be composed of three components. In connection with this it should be noted that, as regards the two ends of the spectrum, the red to the line C and the violet on that side of G, are, on account of their weak luminosity, almost without action on the formation of body colours, that is to say, only that part of the spectrum lying between C and G, Fig. 1, need be taken into consideration. There is thus wanting the carmine red, similar to the extreme red of the spectrum, as well as the violet, and as the middle tones of the still remaining three fairly homogeneous spectral zones, we have then vermilion, yellowish-green, and ultramarine-blue. All body colours must therefore be composed of three components, and they may therefore be considered as primary or fundamental colours, whilst yellow, blue-green, and violet are compound colours, formed from red and green, blue and green, and red and blue.

From this will be seen an extremely clear connection between colour vision and the principle of three-colour photography; the property of colour vision can therefore be very simply imitated by this process, for we simply split up the colours of the original into

FIG. 1.

the above-mentioned three constituents and then combine pictures coloured in an analogous manner. One can thus, even by simple examination of the spectrum, determine with tolerable accuracy the three fundamental colours of three-colour photography, without the aid of more comprehensive theories or experiments. It is also clear that the photographic splitting up of the colours can only be based on the above-mentioned three spectrum zones, and that it is impossible to split up the original colours into more than three parts.

From the above-mentioned colour distribution in the spectrum Helmholtz ascertained the most probable colour sensations, which, following Young's theory, correspond to the three elementary nerve excitations. The choice of these physiological fundamental colours is, as is well known, to a great extent, arbitrary, for it is only necessary for them to comply with the condition that the triangle formed therefrom should include the whole of the spectral colours. By the aid of Fechner's law, however, it is possible to ascertain the fundamental colours which best correspond to these proportions from the connection between wave-lengths and colour sensation. This, however, is a problem by itself, with which one need not complicate the theory of three-colour photography.

If one considers white light composed of but three constituents, numerous phenomena peculiar to pigmentary colours can be explained. The colour of any substance depends on the sum of the reflected rays, thus on the absorption band, or the length and extension of the absorption bands. A substance appears green, for instance, if it almost exclusively reflects the green rays, if thus in its absorption spectrum the red and blue zones of the spectrum appear covered. It appears yellow to us when it reflects the green and red rays thus when it shows an absorption band over the spectrum blue. If, therefore, a substance is to appear red, green, or blue, it must, as shown in Fig. 2, absorb about two-thirds, that is, two spectral zones of the white light; if, on the other hand, it should appear yellow, blue-green, or violet, then the absorption is limited to about one-third of the white light.

This explains the brilliant appearance of yellow, blue-green, and crimson pigments in comparison with the dampened dull impression that all vermilion, green, and blue colours produce. The first-named colours are richer in light and more luminous, for they reflect more light rays than the latter, which beside them appear dull and blackish.

When pigments are mixed the compound colour is the effect of

the rays reflected after superposition of the absorption bands. Vermilion-red, green, and blue colours give, therefore, when mixed one with the other, only blackish colours, for by the combination of their two absorption bands, almost the whole of the spectrum is covered. As a matter of fact, a very dirty yellow—actually brown—can be formed from vermilion and green, and from blue and green very dirty blue-green.

On the other hand, blue-green, crimson, and yellow pigments are particularly suitable for mixing, for when mixed they always leave still one spectral zone uncovered. These colours are, therefore, as is well known, the only ones possible for three-colour printing.

These facts would be quite different had we a simple constant connection between the wave-length of light and colour sensation, and if in the spectrum there were a brilliant violet and crimson—that is, if the spectrum was as shown in II. Fig. 1. Then the photo-

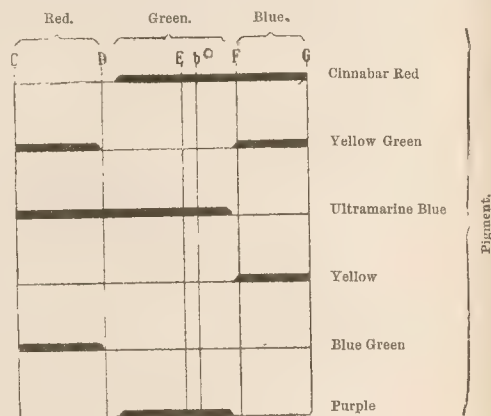

FIG. 2.

graphic splitting up of the colours could be based on an infinite number of equal colour triads and the splitting up into four fundamental colours would be possible, and all pigments of any colour would be equally suitable for mixing with another.

The physiological nature of our eyes necessitates, however, an incongruence between wave-length and colour sensation, through which the theoretical basis of three-colour photography is considerably limited, and the practical execution rendered much more difficult.

A. VON HÜBL.

"THE BOOK OF PHOTOGRAPHY, PRACTICAL AND APPLIED," is the latest of the serial works to be published by Cassell and Co. It is edited by Paul N. Hasluck, and will be completed in 32 weekly parts, the first of which will appear on April 26. The price of each 3d. net.

H. RHEINLANDER AND Co., LTD.—Capital £500, in £1 shares. Objects: To carry on the business of photographers, photo-processors and general engravers, art designers, printers, advertising agents, publishers, picture dealers, and cleaners, advertisement contractors etc. No initial public issue. Registered without articles of association.

THE NEW CAB REGULATIONS.—The Home Secretary has sent the following reply to a letter from Messrs. Speaight (Ltd.), of New Bond Street, who complained that ladies arriving at their studio by cab accompanied by a nurse and child in arms, were caused considerable annoyance by the cabman's insisting upon charging as "an extra person" the baby brought to be photographed:—"Whitehall, April 12. Sir,—With reference to your further letter of the 9th inst., I regard to your suggestion that children in arms should be allowed to travel in cabs free of charge, I am directed by the Secretary of State to say that the provision to which you refer has not been adopted in the new Public Carriage Order.—I am, Sir, your obedient servant, W. P. BYRNE."

## PRINTING PHOTOGRAPH AND BORDER NEGATIVE IN ONE OPERATION.

ORDER negatives usually have the design in "line" on thin paper celluloid, and these are suitable for this method.

Cut out the centre of design, usually opaque, with a sharp knife make a clean edge, then get a mask of thin card or metal with an aperture of the exact proportion of that in the design and a little larger, say  $\frac{1}{16}$  in., if a narrow white line is desired round the photograph in the finished result, and the same degree smaller if a black line is required.

Now take the portrait or other photograph on a plate at least as large as the border design, and preferably in the position corresponding to the aperture in the mask.

Having developed, fixed, and washed this in the usual way, immerse it for a few minutes in formalin or chrome alum, rinse and dry.

When quite dry, place the prepared mask on the film of negative so that the required part shows through the aperture, then cut away through the film all round.

Now soak the negative in hydrochloric acid 1 part, water 7 parts, for a little while, and then rub the edge with the finger to see if the mask will come off easily. If not, give it a little longer and try again.

The film should peel off in one piece leaving the required part with a clean edge on the plate. Care should be taken not to rub the plate.

The plate is then rinsed and dried, when the border design can be attached with its aperture corresponding with the negative left on the plate and the two printed together.

The designs being in "line," it does not matter if they are over or under exposed according to the density of the negative, but the borders may be adapted by extra masks or coats of tissue paper or matt varnish.

It should be noted that it is almost impossible to get the edges of the aperture of design and the bit of negative to correspond exactly, it is better to have one smaller than the other so as to print a round.

D. B.

## Exhibitions.

### PHOTOGRAPHS BY MRS. CALEB KEENE.

I confess that we were a little surprised to find a temple dedicated to art in the upper floors of a great house at the Hyde Park Corner of Piccadilly, and it was not without a little trepidation that we threaded a way through passages where an open door here and there showed signs of secret domesticity in the shape of gleaming brasses and snowy coverlets. Can it be possible, we asked, that Mrs. Caleb Keene receives, as did the ladies of the eighteenth century, her sleeping apartments? A timely hint from an attendant turned us steps into a small gallery, lighted from the top, adorned with classic capitals (without shafts) and lined with the regulation brown paper. This is the "Art Gallery" of the Lyceum Club, 28, Piccadilly.

Here Mrs. Caleb Keene exhibits close upon a hundred examples of photographic art. The collection consists very largely of South African views, and studies of the tag-rag-and-bobtail of the sons which seem to be attracted to the neighbourhood of Cape Town. These character studies are perhaps the happiest of Mrs. Keene's efforts. They are all well caught, and some of the subjects that deal with children are quite charming. These little pictures, whether they be of Zulu, Malay, Dutch, or other extraction, are in every case spontaneous and engaging. The picture of a girl holding a baby, held in a shawl, at her back, is one of the favourites. Simple in its design and pleasant in subject. Another, a little girl playing with a toy waggon, is equally engaging. "Boys Round a Camp Fire" something more is attempted. The effect of the artificial lighting makes a very attractive subject group happily posed. "Motherhood" will be recognised by those who to the last Royal Exhibition, where it won no little honour. It presents a mother feeding an infant in the natural way, as she sits beside a bed. It shares the honours here with "Cape Huguenots," white-capped women in an interior. This is a very strongly lit picture, and well composed. We should like to see more of such

obviously pictorial work by Mrs. Keene, for we are disposed to think that she shows to the best advantage in work of that class. Her enlargements from hand-camera work are not always so well studied in their tone-values. "Combing Flax" is, in this respect of values, perhaps the best thing in her show; though the figure of the woman is rather more central than good arrangement required. On the other hand, it must be admitted that the old man who sits at a table reading from a ponderous volume is unconvincing in its tone-values; neither figure nor accessories appear to be what the original negative properly exposed must have given.

In landscape work, this defect is unfortunately of pretty regular occurrence. Not that her work is any different on this account from that of many another pictorial worker whose name stands high. It simply shows that when good photographers attempt to push their work into the domain of good art, they frequently push it to where it drops between and becomes neither. Mrs. Keene's skies are deficient in light, and her ground and other horizontal planes sometimes look as though they were overshadowed by a mighty canopy. Her best landscape, to our mind—and for it we have nothing but praise—is a mountainous view where a winding road stretches down to the foreground, and upon it are stalking three or four natives. Zulus perhaps, who may be going to the mines, but would do very well for native warriors in the picturesque dignity of their figures. This appears to be a more straightforward work technically than most of the enlargements. Another good landscape, capable of great things, with a more natural treatment of the light, is called "From the Slopes of Table Mountain." It has a fine Corot-like design, showing a distant view of a gleaming town in a hollow seen from between near trees densely massed upon the one side and thinly disposed upon the other.

Of a few portraits, the best is that of Sir David Gill, which is excellent in its easy pose and fine character.

We should say that Mrs. Keene's technique rises to its highest in her extremely interesting collection of botanical studies, made from plant life in South Africa; but embracing many varieties common to this country. We were pleased to learn that governmental help has been accorded to the author of these studies, and that they are being officially put to the educational purposes for which they are truly fit, and for which they were intended.

"THE TRIBUNE" PHOTOGRAPHIC EXHIBITION.—Monday next will see the opening of "The Tribune" photographic exhibition, which is to be held in connection with "The Tribune" amateur photographic competition, particulars of which were announced in our columns for April 12. The popularity of the competition is demonstrated by the large number of entries received, and the judges, Messrs. A. Horsley Hinton, Stephen Reid, Carl Hentschel, George E. Brown, J. H. Lunn, and the Editor of "The Tribune," were able to select a number for awards. The winning photographs will occupy a prominent place in the exhibition, and the prizes will be distributed by Sir J. Benjamin Stone, on Friday, May 3. Other leading features of the exhibition will be pictures lent by Sir Benjamin Stone, a large collection of amateur work, and exhibits by many leading photographic firms, including the most modern designs of cameras and accessories. Demonstrations of the latest processes, etc., will be given at frequent intervals, and expert advisers will be in constant attendance. The exhibition should prove of considerable interest and value to all interested in photography, both amateur and professional, and we anticipate a large number of visitors for it. The exhibition will be opened at 12 noon, on Monday, April 29, and will continue for one week only. Admission will be free daily, from 12 to 8 p.m., at "The Tribune" Rendezvous, Bouverie Street, London, E.C.

The following is a list of the exhibiting firms:—

Adams and Co.	The Leto Photo Materials, Ltd.
Adhesive Dry Mounting Co.	J. Lizars.
Benetfink and Co., Ltd.	Mattos, Ltd.
Birmingham Photographic Co.	Newman and Guardia
Butcher and Sons, Ltd.	The Paget Prize Plate Co.
W. Butler ("Swincam").	The Rotary Photographic Co.
J. H. Dallmeyer, Ltd.	Sanders and Crowhurst.
Elliott and Sons.	Service Photographic Co.
A. W. Gamage, Ltd.	Spier and Pond.
The Glazeit Factory.	Standard Patents Co.
C. P. Goetz.	London Stereoscopic Co.
John J. Griffin and Sons, Ltd.	Taylor, Taylor, and Hobson.
Houghtons Ltd.	Chas. Tyler and England Bros.
Ilford, Ltd.	Watson and Sons.
Thomas Illingworth and Co.	Wellington and Ward.
Johnson and Co., Ltd.	Charles Zimmermann and Co.
"Kodak" Co., Ltd.	Carl Zeiss.

## Patent News.

The following applications for Patents were made between April 8 and April 13:—

- CHANGING BOXES.**—No. 8,132. Improvements in and relating to change boxes for photographic and other like purposes. Sidney Herbert Bath, Holly Cottage, West Street, Carshalton, Surrey.
- FILMS.**—No. 8,174. Improvements in photographic film rolls. Edward Crawford Davidson, 18, Southampton Buildings, London.
- SHUTTERS.**—No. 8,175. Improvements in or relating to devices for operating the shutters of photographic cameras. Alfred Greeff and Robert William Greeff, 70, Chancery Lane, London.
- CAMERA ATTACHMENT.**—No. 8,192. Extension or attachment to cameras for taking larger photographs than the camera is constructed for. William John Reavell, 5, Southdean Gardens, Wimbledon, Surrey.
- PLATES.**—No. 8,440. Improvements in photographic plates. James Booker Blakemore Wellington, 53, Chancery Lane, London.
- COLOUR PHOTOGRAPHY.**—No. 8,601. Improvements in screens for colour photography. Frank Wordsworth Donisthorpe, Hohenfels, Combe Down, Bath.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**MAGAZINE CAMERA INDICATOR.**—No. 16,933. 1906. An indicator is provided on magazine and like cameras to tell the operator whether the plate in position has been exposed. A conveniently shaped aperture, which may be glazed or protected with transparent celluloid, is provided in the side or upper surface of the instrument. Behind or below this aperture is a sliding or pivoted plate, coloured or printed in such manner that when one portion is seen through the aperture the operator knows that the exposed plate is still in position facing the lens, and when the other portion appears it informs the user of the instrument that the plate has been renewed.

The sliding or pivoted plate is connected by levers, or otherwise with the trigger of the shutter or exposing trigger, and with the lever of the apparatus for renewing the plates; or it may be connected with the spring mechanism for easing the fall of the plates after exposure, the exact form and arrangement of the mechanism depending on the form of the camera to which the invention is applied.

When the exposing trigger has been operated the indicator is left in such a position that the operator can see at a glance by the colour appearing in the aperture that an exposed plate is in position; when the lever of the changing apparatus has been operated the indicator is reversed so as to inform the operator that a fresh plate is in position. William Leigh Lawrence, 1, Partridge Road, Roath, Cardiff.

**PRINT WASHERS.**—No. 7,057. 1906. This invention relates to apparatus in which the prints are kept from being exposed to the air while under treatment, while at the same time allowing the water in which the prints are soaking to be completely changed periodically. The apparatus also provides for keeping the water surrounding the prints free from agitation. A tank or receptacle is made in which the plates, prints, or films are placed in the usual racks or suspended by clips. The tank is about twice the height of the plates or articles to be washed.

The water is run continuously into a funnel tube, called the inlet tube, at one end of the receptacle, which may consist of a semi-circular tube fastened on the outside of the tank, and reaching to or near the bottom, or a circular funnel tube fastened inside the tank. At the bottom of the inlet tube a series of holes are made, to admit water to the tank. If required, a simple overflow tube can be used inside this inlet tube to prevent overflowing. The inlet tube conducts the water into an intermediate chamber formed by a partition across the receptacle, the partition being perforated with small holes at the upper portion. The water issues from the funnel tube through the perforations in its bottom,

and rises in the intermediate chamber, and overflows through the perforations in the partition plate into the main tank or receptacle gradually covering the plates. In the intermediate chamber is further provided a bent syphon tube, the inlet leg of which is fastened through the bottom of the partition forming the intermediate chamber, the outer leg passing through the side of the tank just below the semi-circular inlet tube.

When the water reaches the top of the bent syphon tube automatically and rapidly empties off the lower portion of the water in the main tank or receptacle, which tank is provided with a false bottom perforated with holes, and just covers the inlet leg of the syphon tube.

This syphon tube has a hole pierced in the inlet leg a little above the top of the non-perforated portion of the partition forming the intermediate chamber, and over this hole is fastened a metal cone, the lower edge of which is a little above the partition which forms the intermediate chamber. When the surface of the water reaches the bottom of the cone of metal, air is admitted, which passes through the hole under the cone, at once into the syphon tube, and so cuts off quickly the action of the syphon. This metal cone is so arranged at such a height that the prints in the tank are left covered with water, and the process is continued automatically.

By this means the water which is in contact with the prints and the like is kept free from agitation, whilst the tank is filled and the incoming water does not mix with it, and is automatically completely changed periodically without the prints being exposed to the air or subject to any violent agitation when the water is changed. This bent syphon tube can either be entirely within the tank or can have the inlet leg inside and the outlet leg outside, or can be entirely outside the tank. In the latter case, however, the inlet leg of the syphon tube must be attached to the outside of the tank at that level at which it is required to cut off the action of the syphon and the hole then bored through side of tank and inlet leg of syphon tube, and a semi-conical piece of metal fastened over this hole, inside the tank. Edgar Mar Chapman, Cairnsmore, Manor Road, Scarborough.

**CINEMATOGRAH CAMERA ATTACHMENT.**—No. 9,987. 1906. The invention relates to an attachment to a camera by which a series of pictures can be taken in consecutive order upon a photographic plate or film, and to apparatus and mechanism suitable for showing the result of such work, either projected upon a screen viewed through a lens. The plate to be exposed is moved backwards and forwards in a sinuous path, so that a series of photographs may be taken upon the surface of such plate.

A frame is made, which may be in the form of a box of suitable dimensions and size for attaching temporarily or permanently to the back of a camera in the position usually occupied by the dark slide. Connected with the front portion of the before-mentioned attachment is a shutter. By preference a flat shutter has been found to act well for the purpose. The shutter may be of the disc pattern, with a portion of the same removed such portion corresponding with the period or length of exposure the opening being regulated according to the light and the subject. Placed in a horizontal frame within the attachment is a suitable plate holder. On the back of this, or in any other suitable position, are a number of projections or studs, forming a rack spaced out in such a manner that each projection or stud corresponds with the position intended for a picture on the negative plate. A toothed wheel, pin, disc, or crank is made to revolve at a uniform and predetermined rate of speed. The teeth of such wheel, or the projections from such pin disc while revolving engage in the projections or studs upon the back of the plate holder and cause an intermittent, regular, and positive movement of the latter. The first horizontal movement of the plate holder, which may be from right to left, is of such description that when the plate holder has arrived at the beginning of the stroke it descends bodily in such a manner as to allow the revolving teeth or studs on wheel disc to engage in a higher row of pins, or projections, in order that a fresh vertical position may be given to the row of pictures upon the negative plate. The continuation of the revolutions by the before-mentioned disc or pinion carries the plate along on a horizontal plane, alternately from left to right and from right to left, until the whole,

greater part, of the plate has been covered with pictures. It is, of course, understood that the same motion that causes the revolution of the wheel or pin disc will, by means of gearing or other mode of transmission, revolve a shutter, so as to cut off the light from the lens to the negative plate, during the horizontal or vertical movement of such plate.

The second portion of the invention consists of a suitable means of holding and exhibiting the positive (by preference made of paper) taken from the negative produced as before-mentioned. Essentially the arrangement is in the form of a holder, into which the paper or glass positive can be easily fitted. A clockwork or manual means of transmitting power for working the plate and shutter, as before described, may be combined with a lighting arrangement for throwing sufficient light upon the picture, either by means of a condenser or otherwise and a suitable lens, magnifying glass, or the like, for increasing the size of the picture, as seen on the positive paper or plate. It is understood that should the apparatus be used in daylight probably no artificial light will be required. James Preston Cribb, 127, Chichester Road, North End, Portsmouth.

The following complete specification is open to inspection before acceptance:—

LOUR PHOTOGRAPHY.—No. 7,217. 1907. Process for the production of coloured photographs. Smith and Merckens.

### New Trade Names.

CRYPLAN.—No. 290,504. Photographic lenses included in Class 8. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C., opticians and lens makers. February 16, 1907.

DESIGN, an eagle with outspread wings, perched on piece of stone.—No. 290,637. Photographic mounts and albums included in Class 39. Fordham and Company, Ltd., Victoria Works, Victoria Road, Walthamstow, Essex, photographic mount and album manufacturers. February 21, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### The Swing-Front.

A little known feature of the swing-front (says Mr. C. Welborne per, in "The Photographic News,") enables us to effect a very useful adjustment that is quite impossible with the swing-back. Suppose the view to include a near foreground object represented at the top of the focussing screen and a very distant object, the image of which falls in the centre of the focussing screen. The usual remedy is to stop down, but another one sometimes employed is to use the swing-back and tilt the screen backwards until both images fall on the surface. You thus obtain sharp focus with a large aperture, but at the expense of distorting the apparent perspective of the view. The swing-front, however, offers another method of securing a similar effect without disturbing the perspective. Assume that the lens is free from distortion (or rectilinear), and that it has a flat field, or will produce a flat image of a flat object; and also assume that it is being used for the purpose of representing a very distant flat object. If the image is flat, it is manifest that the distance between the lens and lens is greater at the margins than in the centre, or, in other words, that the focal length of the lens is greater for oblique than for direct light. It is easily obvious that this must be so if a flat image is to be produced. Suppose now we swing the lens so that it points to the near object. This will now be represented by direct light, and by the shortest focal length of the lens, whilst the distant object is represented by oblique light and a greater focal length. The image of the near object will therefore move forwards towards the lens, and that of the distant object backwards from the lens, as the latter is swinging from one position to the other. The two images thus move in opposite directions. The one that was previously in front of the plate moves backwards, and the other that was behind the plate moves forward; hence, at one particular angle of swing both will be on, or very nearly on, the plate, and both will be in focus.

### Applying Passe-Partout Binding Strips.

A simple and time-saving method (says a writer in "The Amateur Photographer") is to first cut your four strips exactly the size of the edges of the glass, then take each in turn and fold and crease it the full length of the strip, either into one-half or one-third of the width, according to the width of border desired. Then open the creased paper to a right angle and run a wet small mounting brush along the portion to be stuck to the glass. Then, keeping the strip still in a right angle shape, slide the wet portion to its position upon the glass. To do this, it is necessary to have the sheet of glass upon a thick book, or something smaller than itself, so that the edges of the glass are clear all round. Do each edge in turn, not forgetting to cut the corners off two of the strips to give the appearance of a mitre-joint. Now turn the glass face down upon the table, with the dry edges of the binding standing upright, and all that remains is to drop into position, face down of course, the picture and backboard, wet the edges of the binding, and press down.

### Sensitising Carbon Tissue.

Mr. A. H. Hall (writing in "Photography" on the above subject) says: "Briefly the means adopted are as follows: A 10 per cent. solution of either potassium or ammonium bichromate is made up, using hot water, and when cold the solution is filtered. To each ounce of it an ounce and a half of pure acetone is added. In the case of potassium bichromate a quantity of crystals will be thrown down, but this will make no difference. A piece of tissue is then taken and pinned by its four corners to a stout piece of cardboard, a little of the solution is poured into the middle of the tissue, and is spread quickly and evenly over the whole surface with a broad camel-hair brush. The brushing is continued, backwards and forwards, and up and down, until there is a tendency for the brush to stick. The tissue is then put into a cupboard away from the light, and it will be found dry and fit for printing in about fifteen minutes. Besides ensuring the complete solubility of the tissue, the method has several other advantages. No preparations are necessary until it is certain that a suitable day has been obtained for printing. A dozen pieces can be sensitised in a very short time and at a very small cost.

## New Apparatus, &c.

The Goerz-Anschutz Folding Camera (New Model). Made by C. P. Goerz, 4 and 5, Holborn Circus, London, E.C.

In introducing a new model of its well-known folding camera, the firm of Goerz has fully sustained its position of originator of cameras of this particular type, and has demonstrated its talent for giving practical shape to the extreme requirements of hand-camera users. In its general build the camera in no wise differs from the original pattern, but the improvements are at once evident when the shutter is examined. The most notable innovation in this latter important part of the apparatus is the self-capping blind, a feature which makes for speed of working, there being no necessity to replace the shutter of a roll-holder, charging box, or film pack, when winding the "focal-plane" for the next exposure. The shutter, too, has a quick-action wind, which, likewise contributes to the swift repetition of exposure after exposure, again an important point when a series of negatives are required of a function of short duration. This is not the only new feature of the shutter. The mechanism now provides for "time" and "bulb," as well as for instantaneous exposures, the lever-indicator for obtaining any one of which adjustments moving with sufficient stiffness to prevent any change being made accidentally. The "time" and "bulb" exposures should be made at the lowest tension of the shutter-spring, and therefore the makers introduce a movement whereby the tension is automatically relaxed on the shutter being set to either the "T" or "B" mark.

For exposures by pneumatic release, a time valve is provided which in like manner gives automatically times of  $\frac{1}{2}$ ,  $\frac{2}{3}$ , 1, 2, 3, 4, 5, and 8 seconds, thus supplementing the exposures given by the shutter at "instantaneous," which can be as short as 1-15th of a second.

To these conveniences should be added the further facility of the increase in the exposure (i.e., by widening the slit) after the shutter has been wound, an alteration which is done in a moment and may often be a great convenience on occasions when the light

suddenly decreases after the arrangements have been made for exposure. It should be said, too, that all these adjustments are made from the same side of the camera, and that the right-hand one when the camera is held in its normal position.

One other new feature is the lens attached to the finder-sight, which enables the camera to be brought close to the eye, as it needs to be brought by most people for the position of greatest rigidity, and yet permits of the image being sharply seen in the finder. With all these additions, each of which is not merely an alteration made for the sake of calling attention to it, but it is actually a gain in practice, the Goetz-Anschutz should continue to merit the endless high opinions which have been entertained of it in the past.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, APRIL 26.

Loughton Photographic Society. "Rambles Round Loughton with Camera and Cycle." W. Vincent.

SATURDAY, APRIL 27.

Woodford Photographic Society. Outing to North Weald and Toothill.  
Bowes Park and District Photographic Society. Outing to Hampstead Heath.

MONDAY, APRIL 29.

Preston Camera Club. "Lowestoft and the Broads."  
Stafford Photographic Society. Annual General Meeting.

TUESDAY, APRIL 30.

Royal Photographic Society. "With a Hand Camera to the Niagara Falls."  
H. O. Klein, F.R.P.S.  
Hackney Photographic Society. "Theory and Practice of Time Development."  
Messrs. Kodak, Ltd.  
Leith Amateur Photographic Association. "What Can be Done with a Hand Camera."

WEDNESDAY, MAY 1.

Borough Polytechnic Photographic Society. First Print Competition.  
Edinburgh Photographic Society. "Night Photography." Robert Dykes.  
Everton Camera Club. "Retouching Bromides, &c." Demonstrated. The President.  
North Middlesex Photographic Society. Lantern Slide and Print Competition.  
United Stereoscopic Society. "The Rise and Development of the U.S.S." A. T. Mole.  
Central Technical College Photographic Society. "Emulsion Making." Wm. Cullen.  
Croydon Camera Club. "Odds and Ends and Home-made Apparatus."

THURSDAY, MAY 2.

Workshop Photographic Society. "The Photographic Lens."  
Tunbridge Wells Amateur Photographic Association. Open Night.  
Handsworth Photographic Society. "Making Enlargements." A. A. Major.  
London and Provincial Photographic Association. "Gum Bichromate." H. Stewart.  
North London Photographic Society. "A Dive into Belgium." W. L. F. Wastell.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held April 23, Mr. J. C. S. Mummery, president, in the chair. The second of the two lecture demonstrations by Messrs. C. P. Butler and E. J. Wall was devoted (as announced) to the applications of the spectroscope. A number of lantern slides were used to illustrate the application of high dispersion spectrographic photography to the determination of the elements in the sun and the stars. Reference was also made to the use of the spectroscope in mineralogy, metallurgy, geology, and even botany. The employment of a spectrographic camera for the determination of the colour-sensitiveness of orthochromatic plates was also illustrated, and a series of projections on the screen were made to demonstrate the action of filters in cutting out, more or less perfectly, the different rays of the spectrum. The difference was shown between a yellow filter, which cut out the blue rays but allowed most of the ultra-violet to pass, and one which entirely cut out the blue end of the spectrum.

Mr. Wall exhibited an inexpensive spectrographic camera which he had devised for his own use. He employed a diffraction grating replica, which he mounted in the camera in such a way that he could, by turning it on its mounting, get any part of the spectrum on the plate, or obtain second-, third-, or fourth-order spectra at will. With the exception of the grating replica, the whole apparatus cost only about £1, and was capable of doing all the work which anyone interested in applying spectrographic methods to the testing of

photographic materials could require. After a brief discussion the meeting closed with a vote of thanks to the lecturers.

CROYDON CAMERA CLUB.—Mr. W. H. Smith last week gave "Useful Hints, Photographic and Otherwise." The "hints" included novelty in the shape of "photographic tiles," to which we shall return later.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—On Monday in last week April 15, Mr. F. C. Tilney, R.B.A., lectured on "The Romantic Landscape." The lecturer's remarks dealt chiefly with the painters of the Romanticist school of the 18th and early 19th centuries, examples of the works of Claude, Turner, Wilson, Roberts, and others being shown on the screen. The materials employed by these painters had much similarity—a foreground with figures, middle distance of water, crags, and trees, stone pines and dark cypresses, a ruined temple or castle crowning a near height, and a far-reaching mystical distance of mountain and plain, bathed in soft luminous light. The lecturer showed the important part played in these romantic landscapes by their peculiarities of lighting. The brilliant illumination had an exhilarating effect on the mind of the beholder, while the deep shadows inspired awe and mystery, the magnificent effect of luminous distance marking these landscapes with a quality which, in the present day, has not been equalled. In the concluding portion of his lecture Mr. Tilney gave some sage advice to photographers. He thought that they should always consider their own individual taste in the work. There is too much imitation among them. One may strike an original note. Then others feel it incumbent upon them to take it up and try to improve upon it. Thus a sort of fashion is set in a particular class of subject, but such repetition will very soon pall on one, so the lecturer advised all photographers to strive themselves after originality instead of following in any beaten track. He thought photography could be artistic, but photographers should be imbued with honesty of purpose. The lecturer stated that, as a rule, artists appreciated most the old-fashioned, straightforward photography, and said that the impressionistic "cotton-wool jelly" class of photograph did not go down with artists, being appreciated only by the producers themselves and the few who cultivated that class of work; but if a certain effect, no matter how produced, gave most pleasure to the photographer, he was justified in applying those means to produce the effect aimed at. Mr. Tilney advised photographers to visit the picture galleries and study the works exhibited, and the effects produced by the various forms of lighting and grouping, the work of artists giving a truer insight into the which is really artistic in picture making. At the conclusion of his lecture a cordial vote of thanks was accorded Mr. Tilney, who suitably responded.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—At the meeting held on April 18, Mr. A. Haddon in the chair, Mr. T. E. Freshwater exhibited a very fine series of lantern slides, some being from engravings and some from drawings, but what largely interested the members present was the cases where the slides were shown in duplicate—the one plain and the other coloured—the comparison fully bringing out the advantage of the judicious use of good colouring. Mr. Freshwater also showed some coloured slides which were paintings on glass pure and simple, without any photographic or other base, these, he said, took the artist from four to six days to paint, and sold from fifty shillings upwards. They were exceptionally brilliant and beautiful. Mr. Teape, in proposing a vote of thanks, said that the beautiful colour effects were undoubtedly obtained by the proper use of the greys. Mr. Freshwater remarked that the plain glass had nothing to deteriorate the colour put on, whilst the photographic slide had the black basis, which always more or less deteriorated the colours, however carefully handled.

ILLUSIOGRAPH, LTD.—Capital £600, in 1s. shares. Objects: To acquire from W. K. L. Dickson the benefit of certain inventions relating to illusory entertainments, to adopt an agreement with the said vendor, and to carry on the business of providers of public entertainments, organisers of exhibitions and lectures in connection with animated photography or otherwise, dealers in lanterns, lamps, and philosophical instruments, etc. No initial public issue. Registered without articles of association. Registered office, 41 Holborn Viaduct, E.C.

# Correspondence.

## A NEW METHOD OF MEASURING THE TIME OF PHOTOGRAPHIC SHUTTERS.

To the Editors.

Gentlemen,—Mr. A. Kershaw's letter, published in your issue of April 19, calls for some explanation from me. I regret the misunderstanding which has arisen, and would assure Mr. Kershaw—as Mr. Hunter has already done in his letter to you—that there was no such on the part of anyone to claim as novel any method or device which had already been used by him. Mr. Hunter has expressed his regret in that letter that his paper contained no reference to Mr. Kershaw. I am ready to express mine that in reading through manuscript I did not observe the omission. As Mr. Hunter has explained, the two methods are essentially different, their similarity exists only in the use of a rotating disc with slits, but this is a device which has been employed in optical experiments since the time of Fizeau for the measurement of small time intervals. Mr. Kershaw, in an ingenious way, makes use of the persistence of vision. Mr. Hunter measures—not estimates—the length of a luminous line through the moving slit. As to Mr. Kershaw's visit to the laboratory, Mr. Hunter was not on the staff at the time—he was pointed in December, 1905—and knew nothing of the visit until a few weeks ago. Unless my memory is incorrect, Mr. Kershaw did show me his apparatus; he described the principle depending on the persistence of vision, and I thought it very ingenious. When Mr. Hunter explained his method to me I did not connect it in any way with Mr. Kershaw's. Mr. Hunter's attention was called outside the laboratory to the fact that Mr. Kershaw was employing a rotating disc with slits, but, knowing nothing of Mr. Kershaw's visit, merely referred in his discussion with me to the method as one distinct from his own, without, I think, mentioning names, and I do not, after a lapse of some eighteen months or more, recognise it as Mr. Kershaw's. Had I done so I should, of course, have asked Mr. Hunter to refer to it in his paper.—Yours, etc.,

R. T. GLAZEBROOK.

## PAYMENT AT THE TIME OF SITTING.

To the Editors.

Gentlemen,—In your journal of the 12th inst. you refer to the bad practices that are being followed by Australian photographers in their methods of advertising, and the ridiculous prices at which they offer a 12 x 10 photograph, including a dozen prints; but there is no need to go far abroad to point out absurd advertising practices. Could anything be worse than the enclosed advertisement, intended to attract the attention, not of the hard-working labouring classes, such as the Australian photographers cater for, but the blue-blooded aristocracy of this old country, who are invited, through the medium of an expensive advertisement in an exclusive paper, to come and be photographed where "no tiresome sitting fees are to be paid in advance"?

Any photographer practising in the West-End of London must be fully aware that not one-half of the womenfolk who come into smart studios would think of giving any order after proofs were submitted and fees were charged in advance. This experience must be general, and I should like to know whether the "Morning Post" advertiser has had any "tiresome" experience in this direction.—Yours faithfully,

A. R.

## BLISTERS ON BROMIDES.

To the Editors.

Gentlemen,—I note in your editorial that you purpose shortly "presenting a course of procedure which has proved effective in preventing blisters." Is that really necessary?

An experience of over twenty years convinces me that the course of procedure usually adopted, in its simplest form, with bromides, scarcely be improved upon.

I do not propose to re-write my letter of the 5th, though apparently it was merely glanced at by the critics. As indicated there, any

specific treatment or special bath proves nothing, because bromide paper does not invariably blister.

The excuse of "faulty manipulation," which I notice you put forward, is, of course, the usual "office" explanation of the manufacturer. We all know the value of that and what it means. It is, to put it plainly, mere "piffle." One has to use similar remarks occasionally "to give verisimilitude to an otherwise bald and unconvincing narrative." I have the highest respect for the manufacturer, but there is often a lot of difference between the official explanation and what goes on in the factory.

Now, I remember the first and early days of bromide paper, about the year 1882. I was in the first rush for the sample sheets put up and sold by the well-known Greenwich firm. I believe I was the first exhibitor of bromide prints at a public exhibition (1883). Anyway, I have, with no doubt many others, been working bromide paper from that period to the present. For many years the standard developer was ferrous-oxalate, followed by an acetic acid bath; blisters occasionally appeared in those days, as they do now. I used to make large batches of enlargements, and might do two or three hundred without a blister, then probably—without apparent cause or reason—a few would appear to be—as now—a great annoyance. Later, the metol-hydroquinone developer has been a favourite bath, and deservedly so. For several years past my output has exceeded one hundred enlargements and prints per week. As I have said, we may go on week after week and no trouble, then an epidemic of blisters, not on consecutive sheets, so that one would for the occasion use a different developer, and thus endeavour to meet the vagaries of the paper in use, but in a manner to suggest that the paper is a mixed lot—i.e., not all of one batch, and not of the same degree of excellence.

You say that "a slight dragging touch from the corner of another print" may cause a blister. On the other hand, it may do no such thing, and it certainly will not, if the paper and gelatine coating is in the condition it ought to be, and usually is. If there is nothing wrong with the gelatine you may subject the paper to much rough handling without fear of blisters. I have just developed, fixed, and washed a piece of bromide paper, which was first folded up like a letter, and it comes out at the finish almost without a mark. Obviously if the gelatine coating has got damp in places, or decomposed, or if the faulty manipulation of the manufacturer has resulted in the presence on the market of a paper with an inherent tendency to frill and blister, well, in such cases failures inevitably result.

Any prescription which you might devise would be in the nature of the wholesale physicking of a big staff of workpeople as a safeguard against some possible epidemic, when every able-bodied man, woman, and child is periodically dosed in order that, may be, the ailment will pass by the ill-fed, ill-clothed, and weakly members of the community.

The simple explanation is probably that occasionally an emulsion is spread upon paper when its proper destination is the receptacle for residues.

Bromide paper is made every day in very large quantities, which will not blister, or does not. The small percentage which may, and does, with all the accompanying annoyance, should never be allowed to leave the factory.

In estimating photographic reactions the vehicle, gelatine, is not usually considered; we look upon it as a vehicle simply. The old troubles with dry plates—troubles which, one might almost say, the present generation knows nothing of—were got rid of by the exercise of greater care in the selection and treatment of the gelatine used, and, of course, the surface to which it was applied. And so it is with bromide paper. Accidental errors in manipulation and temperatures no doubt cause the trouble to a large extent. Gelatine in a moist condition decomposes very quickly, putrefaction sets in at certain temperatures at a very rapid rate, and some of this partially decomposed stuff gets used, mainly, no doubt, through inadvertence.

There is in development, as every experienced photographer knows, a sufficient margin of safety to cover the varied methods and environment of numberless photographers, and the greater majority of these are reasonably particular in their choice of chemicals and in their endeavour to ensure a proper workable temperature, and the results are invariably good, provided the material is also of normal quality.

—I am, etc.,

J. PRIKE.

Nottingham

## THE MISUSE OF CHEMICAL EQUATIONS.

To the Editors.

Gentlemen,—I was very pleased to see your editorial note in the Journal drawing attention to the misuse of chemical equations. As you say, the employment of formulæ to represent a chemical reaction is of no value unless it has been proved correct by analysis. I have found in my practice as a chemist that this misuse of formulae is not confined to writers of photographic matters, but is characteristic of a certain class of writers on all subjects in which the science of chemistry plays a part. I find that, as a rule, the more superficial a person's knowledge of chemistry is the more ready is he to flourish with chemical symbols, and I think this rule is well instanced in the equation quoted by you in your note, where the silver is represented as consisting of six nascent atoms. I say this, of course, without prejudice, as I have no idea by whom the original article was written, but seeing that these incorrect formulæ are likely to mislead students I hope your note will have the effect of deterring other writers from expressing their theories of chemical reactions in symbols.—Yours very truly,

ANTHONY J. PRESTON.

37, Grove Lane Camberwell, S.E.

April 23, 1907.

## Commercial &amp; Legal Intelligence.

**ALLEGED POSTCARD FRAUDS.**—A sequel to a case which was reported last year in our issue of April 13, cropped up in the Lynton Police Court last week, when Joshua Wm. Humphreys, of Payne's Yard, Blandford, photographer, should have surrendered to his bail for sentence in regard to a charge preferred against him six weeks previously by Rose Phillips, of Gosport Street, of obtaining money by false pretences, but did not appear. The case was in reference to a deal in postcards, defendant having taken orders and money from prosecutor and Mr. W. F. Aldin, of Pennington, but never executed these orders. It appeared defendant had since executed Mrs. Phillips' order, but had not sent her a balance of 6s due on this particular "deal." In a letter he had sent, he promised to pay shortly, and also execute Mr. Aldin's order (1,000 picture postcards for 50s., payment for which was made by cheque, which defendant had cashed).

Mr. Aldin was in the Court, and asked for a warrant for Humphreys' apprehension on this new second charge.

The Mayor having read the letter, said defendant seemed to have miscalculated the date upon which he had to come up to receive judgment, but Superintendent Wakeford said the man had been duly warned by the Dorset police.

After a good deal of explanation as to the circumstances surrounding the case, Mr. Aldin's application for a warrant was granted, and further proceedings in regard to the first charge against the accused were ordered to stand adjourned pending the decision in this second case, which will come before the county magistrates.

**A CHISWICK BANKRUPTCY.**—At the offices of the Official Receiver for the Brentford district, on Thursday last, the statutory meeting of the creditors interested under the failure *re* Carl Stackemann, photographer, 4, Heathfield Terrace, Chiswick, trading as The Photographic Tourists' Association, was held. The statement of affairs filed by the debtor disclosed gross liabilities amounting to £790, of which £511 1s. 3d. was due to unsecured creditors. To partly secured creditors £76 11s. 5d., the value of the securities being returned at £25, thus leaving a balance of £109 7s. 3d. to rank as a debt, and making the total liabilities expected to rank against the estate for dividend amount to £620 8s. 6d. The total assets were returned at £193 9s. 7d., from which £68 0s. 1d. have to be deducted for the claims of preferential creditors payable in full, leaving the net assets at £36 9s. 6d. thus showing a deficiency of £584 19s. It appeared from the statements made by the debtor to the Official Receiver that he commenced business about thirty years ago, having no capital of his own at the time. He had always personally superintended his business, and had kept the usual books of account. His profits have amounted to about £6 per week. He alleged his failure to have been caused through robbery by assistants and loss of a lawsuit, also to illness in his family. Eventually the estate was left in the hands of the Official Receiver for summary administration in the usual manner.

## Answers to Correspondents.

\**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*

\**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

\**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 2A, Wellington Street, Strand, London, W.C.*

\**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, &c. Two unmounted copies of each photograph must be sent with fee.*

## PHOTOGRAPHS REGISTERED:—

F. Marshall, 10, Bridge Street, Blaydon-on-Tyne. *Photograph of the H. F. N. Clavering.*

E. J. Moorhouse, 102A, King Street, Egremont, Cheshire. *Photograph of Lay of Foundation Stone of Presbyterian Church, Corner of Manor Road and Bank Road, Egremont, Cheshire.*

J. Burton & Sons, 3, Haymarket, Leicester. *Seven Photographs of E. Oppenheim.*

W. Norcliffe, 34, King Street, Ulverston, Lancashire. *Photograph of a Royal Mail Van.*

H. Abba, 48, Holderness Road, Hull. *Photograph of the Hull Queen's B Staff.*

J. Holloway, 32, Cambray, Cheltenham. *Photograph of Dr. Bagot Ferguson.*

J. B.—(1) We have not yet had the opportunity of testing one. From the charts which have been published we should say would be equal. (3) If you mean as originators, we say no.

**AMATEUR.**—Many thanks for the specimen you send. The idea very old, and the results are not, as a rule, satisfactory practical work on account of the paper grain being so prominent. In using real negative paper this is reduced to a minimum.

**COPYRIGHT.**—Will you kindly tell me how long the copyright lasts in an engraving from a painting? The engraving was published in 1871. I have had one brought in to be copied, and am wondering if it is safe to copy it.—B.

Engravings enjoy protection for 28 years from the date of first publication, which should be stated on the print.

**COPYRIGHT.**—Our football team engaged a photographer to photograph them before playing a match one day last year. The photographer did not turn up, so we sent a trap for another, who photographed them and supplied them with the photograph ½-plate, mounted. Two months after he had completed his order for ½-plate we asked him if he would do us two dozen of the same group on postcards. This he refused to do, so we got another photographer to copy and print the postcards. The photographer that took the group now threatens proceedings the party selling the postcards does not stop the sale and has him the negative. What had we better do?—FOOTBALL.

Nothing. The photographer has not the faintest right in the negatives. He was paid for his work and the copyright is vested in those who paid him. You may refer him to an article in the "British Journal Almanac" for 1906, where this question is fully dealt with.

**BROMIDE PRINTING.**—I am trying to work a quick-printing machine but up to now have failed to obtain good results. I find it necessary to use a quick bromide card, with which I have had experience; hitherto I have been working gaslight cards, with every satisfaction. With a quick exposure of, say, one second I get a poor, flat picture, which takes some three or four minutes to develop with amidol and brush development. In my experiments I have used a good, clean, and plucky negative, such gives a good brilliant black, with a gaslight card. We have been printing and developing about 300 cards in from three at a half to four hours, one filling the frames, one exposing, &c.

developing, and a boy at the fixing bath. My desire is to get through more in less time. Prices are coming down, and it shoves one to get through work quickly in order to compete with others who are doing a matt bromide at 1d. retail. I develop some little distance from the gas, with a double thickness of azed yellow calico. I shall be glad if you can suggest a likely use for my failures.—BROMIDE POSTCARDS.

We should say you are fogging your paper with too strong a developer. Try the following, which should develop fully in one to two minutes:—

Metal	80 ozs.
Soda sulphite	6 ozs.
Hydroquinone	150 grs
Potass. carbonate	2 ozs.
Potass. bromide	50 grs.
Water	80 ozs.

FOR STUDIO.—I am putting in a window in order to convert a building into a workable studio. The window is about 10 ft. square, but unfortunately it faces the south, the only side of the building available. Would you kindly inform me what would be the best sort of glass (for the said window) to obstruct the direct rays of the sun, and at the same time let in the maximum light? I am having the frame made to take glass panes of any size, so that the glass would require to be of good weight, and as little colour as possible.—M. C. G.

We cannot suggest anything better than ground glass, except in form of flexible gelatine decoration, which is sold by Reinemann & Co., New Zealand Avenue, Barbican, E.C. It is obtainable in various very slight patterns, as well as, we believe, quite plain and is applied simply by moistening with water.

DEVELOPER.—(1) Some of my negatives recently have been stained with pyro-soda developer, perhaps through insufficient of the latter from a solution a little old (the sulphite, I mean), stocked in a bottle alone. The difficulty has arisen when specially making a developer with dry pyro, carbonate of soda, and sulphite separate. The point more particularly is that the stain has apparently been removed after passing through alum and citric acid, but has returned after washing and drying, making the negative very hard, and the detail in the whites almost unrecognisable. Why the return of the stain after washing? (2) I was interested in your remarks about the pyro-soda developer. It has been my habit to mix the sulphite with pyro, and keep soda carbonate separate, and add latter according to exposure given and class of negatives required. This keeps well and works well for portraits in studio, according to your formula. I should be glad if you would recommend the proportions which would be likely to give the result for very short exposures. (3) My experience with the Kodak formula for films—

Sulphite soda	6 ozs.
Pyro acid	$\frac{1}{2}$ oz.
Water	32 ozs.

that it does not keep in a useable condition for one month, which is inconvenient, because in the county we are not developing films for customers very frequently, and it causes a great deal of waste. Would more sulphite improve it without reducing power of development? One wants a really quick developer for hand camera exposure.—BROMIDE POSTCARDS.

(4) Yours is a common experience. Acid baths often discolour staining material without removing it, and then the colour is liable to return. Acid is most effective in the fixing bath.  $\frac{1}{2}$  oz. of potash metabisulphite in each pint of fixing bath, does not wash between developing and fixing. The stain is due to your sulphite solution, which will not keep without a preservative. Add one ounce rectified spirit to each pint of solution. This will help to keep it. (2) We are glad your experience of our formula is so favourable. We use the same formula for shutter exposures. For extremely short exposures we should use the same formula diluted, and increase time of development. We have had other complaints with regard to the formula you mention. Bad keeping and great staining qualities seem to be characteristic of it. The formula, however, generally differs from one you give, as sulphuric acid is usually included. For rapid development, try our formula, with only half the amount of meta-

bisulphite, or use the one given on page 303. In latter case you will be safe with the brand of sulphite mentioned, but with certain other brands the solution will not keep well. If you wish to further shorten the time you had better use metol hydroquinone.

CHINESE CLIMATE.—I should be pleased if you could tell me what is the best process to withstand the Chinese climate.—W. D. W.

We regret that we do not know what particular form of training, physical or otherwise, that it is necessary to undergo to enable anyone to withstand the Chinese climate. If our correspondent refers to a photographic process, will he kindly specify whether he refers to negative or positive.

COPYRIGHT.—At Christmas I photographed several views of this town in the snow and sold them for postcards. A postcard dealer bought some from me at twopence each, and has now had them reproduced in a book, "of two views in each book." If I have mine copyrighted, can I prevent him from selling the same without my permission, as mine are the original negatives?—COPYRIGHT.

You can register the copyrights now and prevent further sales by the dealer, but you cannot take action for sales made before registration.

E. P.—The print is dipped in alcohol, squeezed on to the celluloid, and fixed by hot pressure. Messrs. Fallowfield, 146, Charing Cross Road, issue a booklet giving directions and descriptions of the apparatus.

DEVELOPING RAPID EXPOSURES.—I have several times lately been called upon to take very rapid snapshots of rapidly-moving objects (such as horses galloping, etc.), necessitating an exposure of from 1-500th to 1-1000th of a second, and although the results I obtained were very good, I am not at all sure that they might not be improved on by developing the plates in some different manner. I should be very much obliged if you would tell me what is the best developer to use for plates which have had such brief exposures as the above, and what is the most practical and effective method of getting the most out of such rapid snapshots? The plates I have already developed were developed with a pyro-metol developer ("Royal Standard" formula), diluted with four times its bulk of water, and the plates were rocked in a dish during the whole of the development. I believe what is known as stand development is usually adopted by those who are experienced in rapid snapshot work.—ROCKER.

We know of nothing appreciably better than the weak pyrometol you have been using. A tank method, using, say, rodinal 1 oz., water 200 oz., is, perhaps, a little preferable on the score of detail and softness, but the difference is small.

HARRY H. T.—We are obliged to you; but there is no need for us to refer to the matter.

WORRIED.—We advise you to address a letter to the police in the neighbourhood asking them to pay a call.

P. D. P.—There is little to choose between A and B. We have not had an opportunity of testing C.

HALF-TONES.—Would you give me the names of any firms who supply half-tones mounted on plush frames, trinket-boxes, and similar articles. The articles I mean have, I believe, a good sale at all the pleasure resorts. The print is mounted in optical contact with glass, and the glass then, in its turn, mounted on the base. The effect is very similar to "opalines."—F. R.

Messrs. Moores, De Saulles and Co., Stourbridge, supply the frames, boxes, etc. If you require half-tone prints from your own negatives you will require to get them from a photo-engraving firm such as Hood and Co., Middlesbrough, Hamel and Co., Nottingham, or the London Studio. Consult our advertisement pages.

COLOUR-WATER.—1. Your retouching is good enough to secure you a situation in a second-class firm—it is not up to the highest requirements. Your modelling is weak, the "touch" merely a smoothing one, and you remove lines and shadows unduly. 2. In wording an advertisement for THE JOURNAL, state your full qualifications, but we advise that you do not make a special claim upon your school of art and exhibition experience. Photographers want only those skilled in photographic finishing—the two methods are widely different—but you might mention that you possess a general knowledge of art. Your colour work is

also second-class, and we think you should strive after better flesh tints and strengthen your shadows considerably. Flesh, dress, and background are all too monotonous in tone, and require variety and warmth in the shadows and half-tones to liven them up.

**MAKING BACKGROUNDS.**—Can you inform me if there is any book published giving instructions on distemper or flatted oil background painting? Any information assisting in that way will be esteemed.—**ALFRED T. HONEY.**

There is no book published on the painting of backgrounds. If, however, you refer to page 82 of our issue of February 1 last, and page 155 of that of March 1, you will find articles on the subject which will probably be of service to you.

**SALARY QUERY.**—I shall be greatly obliged if you will kindly inform me what salary I may expect to receive in a good-class photography business as receptionist, assistant retoucher, spotter, etc. having just served an apprenticeship of three years as such to a high-class photographer. My age is 21.—**V. L. C.**

This is a difficult query to reply to, as so much depends upon personal ability and business tact, and something on the status of the house to which you have been apprenticed. The salaries of experienced receptionists and retouchers vary from about 15s. to 30s. a week. You would scarcely be classed as an experienced hand at present, we should think.

**WHITE BACKGROUNDS.**—I should feel obliged if you could tell me how to obtain white background effects in my studio. As you will see from enclosed sketch, the studio is 22ft. long by 8ft. wide, with 9 ft. side light 5ft. high, starting 4ft. from floor, with only 2½ft. top light 9ft. long. I vignette all my pictures, but find that background then prints a dirty grey or brown tone in platinotype; and what is the best material and colour to use for obtaining white effects? Do you recommend a slower plate for this?—**WHITE BACKGROUND.**

We scarcely understand your query. Surely you do not desire an absolutely white background behind the head and bust of the sitter, as the margins of the picture should be kept white by the vignetting mask. Colour for white background is white distemper—otherwise, ordinary whitewash—or you may cover a screen with white paper. If you desire a pure white behind the sitter's head and bust, we expect you will have to block out the background in the negative with water colour or black varnish.

**STUDIO QUERIES.**—I am seeking your aid again, through the medium of your valuable paper. I am building a new studio. I enclose two sketches of studios, and I should like to know which you think would be best—the ⅔-span or ½-span. Also, I had thought of dark blue blinds similar to pattern on spring rollers for top light, and on wires for side light. I have Bolas' book on "Studio Construction," but I think there should be some fresh ideas since that was written. Anyhow, I should be pleased to know what you think about these two matters.—**TYKE.**

Both designs are good, and it is quite a matter of taste which is the best. On the whole, perhaps, we should prefer the one shown in sketch No. 1. But, as we have just said, one is practically as good as the other. We should, however, advise you to have the studio somewhat longer—say three or four feet. You will then be able to use lenses of longer focus, and so obtain better perspective in the pictures. The book is a very good one, but after all more depends upon the man who works it than the form of the studio. The sample of material sent will do very well for the top blinds, but for the sides we should prefer a softer one, such as an "art serge," of a similar colour.

**LENS QUERY.**—Will you kindly inform me what make of portrait lens would be suitable for artificial light work? Studio is 14ft. long. I want it principally for taking postcards 5½ x 3½, groups on same, also midgets, if possible. Camera I am using measures 6½ inches from front of lens panel to focussing screen (outside measurement). I do not want to pay a lot for a secondhand one. I should not mind about £3 or less, if you think I can get one good enough.—**F. B.**

The most suitable lens to use with artificial light would be the ordinary portrait lens, but we do not know of one that would take groups (full length) of the postcard size, which is nearly that of the cabinet picture, in so short a studio as yours. A portrait

lens of ten inches focus requires a distance of about 14ft. bet. camera and sitter for a full-length figure, and your camera, of course, would not do for that. One of the anastigmat types of shorter focus would cover the size of the picture you require, but the perspective will not be so good as with a longer lens, and the price would be higher than you mention if it were a large aperture. You had better get price lists from the different makers or dealers, and from them select what will suit your requirements and purse best.

**FADED WRITING.**—Would you kindly answer the following? I have a portrait painted with writing, in ink on back, which is very much faded. Can I do anything to restore or colour ink, so I can have the same?—**I. N. K.**

If the writing was done with the ordinary iron-gallic ink, colour may often be restored by carefully moistening it with an infusion of galls, or with a solution of ferro-cyanide of potassium, slightly acidified with hydrochloric acid. V. ink fades it generally goes to a yellow colour, which, because of its non-actinic character, often can be copied well by photography without further treatment. Have you tried copying it as it is?

**FADED GLASS POSITIVE.**—I notice the query of "Positive" in last week's journal. I have two old glass portrait positives. One is quite spoilt, owing, I suppose, to damp, and I am afraid the other is also going. What can I do to preserve it? It is valuable to me as it is the only portrait I have of a near relative, and although I have had it copied, and also an enlargement from it, the original is of them are satisfactory.—**C. H.**

Without seeing the pictures we cannot give an opinion. If the pictures had been varnished they would not have faded. But, even if anything can be done with them now, as, in all probability, if the film is wetted, it will leave the glass; or if it is varnished the collodion would possibly dissolve when the varnish was applied. The only suggestion we can offer is that you get good copies of them before they decay further.

**PRO.**—We regret that we do not know exactly what is meant by the "Cadett filter," but if we are correct in our assumption that this refers either to the "Absolutus" or "Gilvus" filters, which were specially made for Cadett plates, we can only say that we know of no plate which will work satisfactorily with the form as this absorbed too much of the green. This is obviously the reason why unsatisfactory results are obtained with the plates named. The Cadett spectrum plate was exceptionally sensitive to green, and to compensate for this the filter was made so as to reduce this extra sensitiveness to the average level of other colours. If the filter is a "Gilvus," then a Wratten's panchromatic plate can be used instead of the Cadett spectrum, with very similar results.

**J. HARRIS and Others.**—In our next.

**W. W. L.**—If the subjects are good and the negatives in good condition you may dispose of them through our advertisement columns. We know of no other means.

**R. H. B.**—You must not say "Photographer to the King," but you can state the facts of the case you refer to.

**J. S. D.**—"St. Louis and Canadian Photographer," 3,210, Locust Street, St. Louis, Mo.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

are bound to criticise severely the proposals of newspaper  
publishers in America regarding photographic copyright. (Pp. 326  
28.)

Professional Photographers' Society of New York reports a  
factory agreement respecting the keeping up of prices. (P. 327.)

Royal Academy opens on Monday next. We shall deal with  
portraiture next week. (P. 325.)

conclusion of Messrs. Becks' paper on the "Isostigmat" lens  
on page 330.

experience of Mr. A. J. Garwood in intensification and reduc-  
ers abstracted on page 329 from a paper before the Edinburgh  
Graphic Society.

ters on bromide. Mr. C. Winthrop Somerville states his  
ence. (P. 339.)

further letter from Mr. A. Kershaw, in reference to priority in  
er-speed measurement appears on page 338.

## "COLOUR PHOTOGRAPHY" SUPPLEMENT.

ne-plate process of three-colour photography is advertised for  
rst time in this issue. We give the latest particulars on  
37.

William Gill, of Colchester, one of the few professionals who  
taken up colour work, gives his views on the business side  
(P. 33.)

A. J. Newton condemns the existing practice of fine-etching  
blocks from the black proofs. (P. 34.)

few points in the making of three-colour copies in picture  
es are communicated by a contributor. (P. 34.)

er Karl Worel gives his views of the processes which just at  
t are being talked of in colour photography. (P. 36.)

cautions in the use of liquid colour filters. (P. 35.)

## EX CATHEDRA.

**The Royal Academy—** The much abused—opens its doors again  
for its annual show on Monday next.  
We are unable, before that day arrives, to do more than  
announce the fact and in a few words to give a rapid  
impression of the show. Next week we shall deal more  
fully with the subject and treat particularly of the most  
notable portraits that grace the crowded walls. Alas, for  
artists! Those walls might be crowded five times over and  
then look little less pleasing, so great is the competition  
amongst painters in these days. But "The President and  
Council regret" that this is impossible. The cumulative  
effect of these thousands upon thousands of regrets is  
awful to contemplate, and must certainly be enough to  
blight the remainder of life for the President and Council.  
Taken as a whole, our first glance at the exhibition fills  
us with hopes that upon closer acquaintance we shall find  
it one above the average. People like to rail against the  
Academy; but it undoubtedly harbours the best work of  
the country.

**Sargent and Others.** John S. Sargent, R.A., our Reynolds  
and Gainsborough rolled into one—our  
leading Society painter—adds to his reputation this year  
by painting more for the man in the street and no less than  
usual for the artist. We mean that his work is less of  
an artistic shorthand difficult to read by the uninitiated.  
It is more akin to typewriting (pardon us, Sargent!) inas-  
much as it is rapid, sure, and intelligible to the meanest  
capacity. One work of his, Lady Sassoon, is not to be  
forgotten for its consummate skill and perfect realisation,  
to say nothing of its charming subject. The new Associate,  
Geo. Henry, has not made a splash, but has done better,  
perhaps, by adding more solid and sincere works to that  
long line which has led him to fame after years of obstinate  
Academy rejection. Frank Dicksee, R.A., A. S. Cope, A.,  
and others of similar standing, do their same fine  
things year by year; but next week we shall speak of those  
younger developments of portraiture which aim first at  
being arresting. Portrait painting, like professional  
photography, is a business.

**Canvassing Frauds in Cornwall.** Information reaches us of the visits to  
the country districts of Cornwall of a  
man who, with the aid of a canvasser, is  
steadily working the old method of offering for nothing an  
enlargement from any photograph which is placed at his  
disposal. This gift to the purchaser being said to be the  
means of advertising a new studio being opened in the  
neighbourhood. A few days afterwards the persons who  
have placed their photographs with the canvasser are  
informed that a frame must be purchased, and are per-  
suaded or threatened into paying a high price for a frame

and a rubbishy enlargement, which together are not worth a fraction of the price paid for the former alone. This particular form of fraud has been so often exposed in the newspapers that those who have not heard of it must live in the very remote districts such as those which appear in course of exploitation at the present time by the party complained of by our correspondent who asks for the remedy for such incursions on a photographer's circle of customers. The best we can suggest is that used with success by Mr. T. C. Turner in Hull, namely, the circularisation of the householders with a short statement of the nature of the business. The local press, also, will usually aid in enlightening its readers as to the character of the business. In one case which we have in mind the local photographer accompanied the canvassers on their rounds and explained the nature of the business to his townsfolk.

#### Measures in the Dark Room.

The frequent use of orthochromatic plates, often calling for a faint illumination of the dark room, it is more than ordinarily necessary to have measures which are easily distinguishable in the dull non-actinic light. The need of specially clear lettering on the measures has been experienced less than some means of showing plainly where the measure is and of avoiding knocking it over when the hand is suddenly stretched out to rinse a plate or place it in the hypo bath. In every respect except this of visibility we have always had every reason to be satisfied with the ordinary clear glass measure, and it may perhaps interest some of our readers who have not heard of the simple expedient—we must have mentioned it several times—to point out that a coat of white enamel paint round the base of the measure and round its rim, on the outside, of course, serve as well as anything which can be devised to separate the graduate from the gloom of its surroundings. We have often had reason to feel the comfort of this addition to our glass measures when temporarily denied the use of them in a strange dark room.

#### AMERICAN NEWSPAPERS AND COPYRIGHT IN PHOTOGRAPHS.

We publish on another page a portion of the report presented to a Convention of the American Newspaper Publishers' Association, a careful reading of which will show the feeling which exists among producers of illustrated journals in America with regard to copyright in photographs. The Association has been active in the political sphere respecting the alterations in copyright law, and there can be no doubt that the provisions which are contained in the last paragraphs are what it would wish to see become the law of the United States. The motives of the document are sufficiently evident; nevertheless, we propose to discuss, as briefly as possible, the grievances which are alleged by American publishers to exist under the present legislation, and, secondly, the nature of the proposals which the publishers offer as an equitable remedy for the existing state of things.

We are told that, in the eyes of publishers, injustice is done at present in three ways:—(1) In giving the same degree of protection to a chance snapshot as to a work of artistic or literary genius. (2) In making every copy of a newspaper which contains an infringement of a photograph subject to the penalty of not less than one dollar. (3) By failing to recognise that newspaper reproductions are not such as can be substituted for sales of originals, and that, instead of reducing sales, they tend to advertise the originals and increase their sale.

Let us say at once that we are entirely in accord with the second of these statements. In the case of a newspaper of even moderate circulation the penalty of even the

smallest sum per copy mounts up to a total enormous greater than should be paid to a photographer for infringement. The British law, it will be remembered, states a maximum penalty per copy—namely, ten pounds—but no minimum; yet it was always held until long ago that a coin of the realm must be paid for infringing copy. This custom was quashed by the Court of Appeal in 1901 in connection with the case of *Hilheimer v. Faulkner*, reported in our columns of May of that year. And there is no reason to suppose that photographers in America would not be satisfied with above reasonable arrangement prevailing here.

In regard to the other two matters which are regarded as injustices, the Association must know that its conditions will not hold water for two minutes. It is, we are told, to grant the same degree of protection to a "mechanical" photograph as to literary or artistic compositions. Let us grant that some drawings and paintings are superior as works of art to some photographs. Let us grant that all photographs are wholly bad as art. What has that to do with it? The important matter is that they are bad enough for publishers to want to get their newspapers with them because the public has its heart on photographs as records of events in preference to the work of the artist which may be, and often is, entirely imaginative. A photographer may have been the ends of the earth and have carried his life in his hand to obtain photographs, and because they are art, forsooth, they are to have a lesser privilege of protection than the drawings which Mr. Flake White, draughtsman, sits at home and commits to paper. A photographer such as Mr. Kearton may have spent months in getting half-a-dozen photographs of natural history subjects. Not art, perhaps, but surely entitled to what protection the law of a land grants to methods of graphic description. We cannot now enter upon the question in what way and to what extent a photograph may be differentiated from other forms of art in respect to copyright protection, but it is obvious that the former description of picture is misrepresented in the terms of the report.

Lastly, the report alleges that the sale of photographs is not adversely affected by newspaper reproduction. That such should be the fact in America we cannot believe for a moment. It has certainly not been so in England where the view publishing trade has steadily declined contemporaneously with the rise of illustrated journals and finally received its death-blow at the hands of the picture postcard. The facts, we say, are against the argument that reproduction, either in the crude manner of the daily papers or in the excellent art printing of weeklies, does any good to the sales of the original photographs. In the case of a large proportion of the photographs which appear in newspapers the subjects are of ephemeral interest, have been taken specially with a view to newspaper reproduction, and are of no other value to the photographer other than through the fees for reproduction which he may obtain. The newspaper owner discerns injustice in this payment for work done.

The proposals first put forward by the newspaper proprietors in the desire to remedy these injustices was "the reproduction of a photograph in any newspaper without the process of stereotyping shall not be construed as infringement of the copyright." Stereotyping being a universal process in the States for newspaper production and one which the Americans have applied with great success to the finest half-tone work, this suggestion amounts to the cool request for permission to take every photograph and pay for none.

This proposition when originally made naturally aroused universal indignation, and the report therefore states that it was put forward to "bring matters to a focus."

nittee of the Association has abandoned it in favour of amendments, of which the first is that notice of right must appear very distinctly on the face of the photograph in order to give it protection against newspaper reproduction. In the two other amendments it is properly suggested that there shall be reduction in assessment of damages in the case of newspaper infringement, as well as the exception of newspapers from criminal prosecution for infringement of copyright. While they assent to the two latter claims of the newspapers, the corollary from the "marking" rule, that a photograph may be reproduced by anyone into whose possession it comes unmarked with the word "Copyright," obviously gives the power to the reproducers to do whatsoever they like. A photograph must necessarily bear this marking where near its edge, otherwise it would be useless for reproduction, and therefore there is the opportunity for the reproducer to exculpate himself by trimming off the marked portion and to represent himself, when charged with infringement, as the victim of circumstances. A

certain degree of marking has been required in the United States hitherto, and has proved to the infringers a loophole for escape. Hence we attach very little importance to the committee's recommendation of more prominent marking. It looks to us as though the publishers were unable to find a recommendation which would advantage them and yet be free from the appearance of self-interest, and that therefore they fall back on the "marking" system, which has served them very well in the past.

To sum up, the report of the American Newspaper Publishers' Association is interesting from the fact that the present support of the marking of copies coincides with that of a body in the United Kingdom which has prepared certain recommendations for the alteration of the law of copyright. The newspaper people can hardly be expected to further a provision which will safeguard photographers, and it is therefore easy to come to the unkind conclusion that the British body is actuated by similar motives in recommending that the marking system be applied to photographs.

## PROFESSIONAL MATTERS IN AMERICA.

proceedings of the Professional Photographers' Society of New York, the preliminary report of which appeared in our issue of April 19, have been distinguished (according to the later report which reach us from the "Photographer") by the tireless industry of the tactful "photographer of men," Mr. Pirie Macdonald, who, as president of the society, has thrown himself so utterly into the work of organising the Convention that the Americans have opened the eyes even of the Americans—to whom conclusions come naturally—to what may be done by a body under the impulse of a thoroughly enthusiastic leader. To quote our contemporary:—"Pirie Macdonald (born to be a minister: choosy to be a detective, and forced to become a photographer, as he tells the story—to be taken with a large grain of salt), for the last year has been devoting himself day and night to the interests of the society which made him, for a second term, its guiding head. Thoroughly imbued with the idea that to do a thing well you must do it yourself, he has left nothing to his assistants on the board but a few details for which he himself has no time, and even these details were so carefully mapped out that nothing could go amiss. His head that worked out studio demonstrations, and no one but Macdonald knows how it was to persuade some of these big men to consent to his presence. He it was that figured out the usefulness of getting assistants to tell their studio secrets for a reward. The Labour Union, with its total to date since July 1, 1906, of at least sixty employees placed, is his work alone. Macdonald it was that brought out over one hundred and seventy pictures from over one hundred and seventy individual photographers, members of the society. Yes, the credit for one of the most successful state meetings ever held anywhere belongs solely to Macdonald." The regret of the conventioners was the indisposition of Mr. Macdonald, which was such as to compel his absence from the meetings. Much of the business of the convention has no place in our columns, inasmuch as its interest was local, but we may quote the resolutions adopted by the Rochester section of the society in regard to photographs of schools, a class of subject which has been undertaken at such "cut" prices that it became unprofitable. The Rochester photographers in the society, therefore, decided to stand by the following resolutions:—

### I.

Resolved that the members of the P. P. S. of R. will quote lower prices to the committee of the various schools and colleges

than the price set for the class in which their respective names appear.

### II.

Resolved that definite written contracts be entered into between the members of this Society and the school or class committees, and that a full list of the names of class, together with \$1.00 for each name, be deposited with the member, before prices take effect.

### III.

Resolved that no further reductions of any kind whatsoever be made, and no concessions or inducements or promises of any description, either directly or indirectly, be made to Committee or any member of Committee.

### IV.

Resolved that at no time shall sample pictures be given committees to be taken out of the studio for comparison, or any other reason.

### V.

Resolved that any irregularities shall be reported immediately to President of the Society, who shall at once appoint a committee of three members to investigate and report within three (3) days.

### VI.

Resolved that this agreement shall remain in force and binding for one year, from January 1, 1907.

### VII.

Resolved that the prices herein agreed upon shall not be quoted to classes of less than ten (10) members.

### VIII.

Any member signing this agreement, and after investigation it is found that he has in any way broken it, shall forfeit his membership in the P. P. S. of R. under Art. III., Sec. 6, of Constitution, and have his certificate revoked.

In addition to the utmost confidence and friendship that has been established, we have worked out, after much careful consideration, what is known as the Certificate Plan, the object of which is to elevate our profession in the eyes of the public.

Certificates for the year 1907 have been issued, and are now displayed in our street show cases.

To obtain their certificates members submitted prints of their own work not bearing their name, to three judges, also photographers. The pictures were judged on their merits in lighting and posing, and general effect, the last including mounting and finishing; and certificates were issued to all who obtained at least (75 per cent.) seventy-five per cent. of the total marks given. In considering the question of granting a certificate the grade of work was also an element. The man who charges moderate prices for his work would not, of course,

be expected to produce the grade of work of the higher-priced men. The aim is to certify to honest and creditable work and to give assurance of reliable treatment to customers. Our daily papers have made it plain to the public that we do not wish to control prices in any way, but that our membership is composed of reliable photographers in whom they can place confidence.

It is the sense of your members "Up-State" that we are decidedly "in it," and all are willing to do our share towards bettering the condition of professional photographers.

In its election of officers, the society exhibited a remarkable independence. It elected an entirely new set of men, and its action is applauded by those conscious of the dangers to such a

body which may be created by the usual policy of recognizing the good service of a man in one position by electing him another for which he is probably not fitted.

The new officers are:—

President—A. F. Bradley, New York City.

First Vice-President—J. D. Schroder, Troy.

Second Vice-President—C. H. Smith, Rochester.

Secretary—L. Minor Sherow, Ossining.

Treasurer—Al. Lloyd, Amsterdam.

We are compelled to hold over the reports of the "Suggest competition and of other features of the Convention until week.

## PHOTOGRAPHIC COPYRIGHT IN AMERICA.

[In view of the rumours that attempts are to be made to bring a Bill for the modification of Copyright Law before Parliament an interest should be discovered in the attitude which newspaper owners in America have taken towards photographers, as well as in arguments they have used. The following report is part of one presented to a convention of the American Newspaper Publishers Association, and is reprinted by our contemporary, "The Master Printer and Newspaper Owner."—Eds. "B.J."]

The committee quoted Section 4,965 of the Revised Statutes, as amended by the Act of March 2, 1892, and said:

"The effect of this law is to impose as a penalty upon a newspaper infringing the copyright of a photograph the forfeiture of one dollar for every sheet of the same found in its possession, either printing, printed, copied, published, imported, or exposed for sale; with a minimum penalty of \$100 and a maximum penalty of \$5,000 for the infringement of copyright of a photograph made from any object not a work of fine arts, and a minimum penalty of \$250 and a maximum of \$10,000 for infringements affecting photographs of works of fine arts.

"Existing law makes the wilful unauthorised representation for profit of a copyrighted dramatic or musical composition a misdemeanor punishable by imprisonment, and provides the remedy by injunction in such cases. No other infringements are misdemeanours under existing law.

"The proposed new law separates wilful and unwitting infringers of photographic copyright. It declares every wilful infringement of copyright for profit to be a punishable misdemeanor. On the other hand, the unwitting infringer of photographic copyright is no longer to be threatened with any arbitrary penalty, though the equitable remedies against him are enlarged. An injunction lies restraining his infringements. He is liable to pay the copyright proprietor actual damages and profits, or in lieu thereof such damages as to the court shall appear to be just, not to exceed in any case \$5,000.

"Under existing law there is a forfeiture by the infringer of \$1 for every sheet 'found in his possession'; under the proposed law there is suggested as the basis of an estimate of damages \$1 for every copy, not merely found in the infringer's possession, but made or sold by him or his agents. Under the existing law there is an arbitrary minimum of penalty of \$100 or \$250, according to the character of the photograph; under the proposed law the recovery is no longer of a penalty, but of liquidated damages, and the arbitrary minimum of recovery is eliminated.

"The wilful infringer for profit of photographic copyright may be punished much more severely than under existing law; the unintentional infringer inflicting no actual provable damages, and newspaper infringers are usually of this kind, may, in the discretion of the court, be required to pay the smallest of merely nominal damages."

After quoting the language of the Senate and House Bills, which are identical, the report said:—

"The first draft of the Copyright Bill was, in a few particulars, less favourable to the infringing newspaper than the Bills under consideration. For instance, Senate Bill 6,330, gave to the copyright proprietor, in lieu of actual damages and profits, 'such damages as to the court shall appear just, to be assessed upon the following basis, but such damages shall in no case exceed the sum of \$5,000, nor be less than the sum of \$250.' The latter Bills, instead of directing damages to be assessed on the basis of \$1 for every in-

fringing copy, broaden the discretionary power of the court providing merely that, in assessing such damages the court may in its discretion allow the amounts as hereinafter stated, and eliminate entirely the \$250 arbitrary minimum of damages.

"In making these changes the joint congressional committee responded in part to the representations made to it by the copy committee. This committee had, in the name of the publishers' association, represented that injustice is done (1) by giving to the mechanical maker of a kodak snapshot the same protection then given to the author of a literary, artistic, or musical composition; (2) by treating the imperfect reproduction or imitation in a newspaper of a copyrighted photograph as causing every copy of the offending issue to become, in the eyes of the law, an infringing damage-producing copy of such photograph, subject to the penalty of not less than \$1 for every such copy and to other punishment; and (3) by failing to recognise that newspaper reprints of photographs are not such reproductions as can be substituted in sales for originals, and that instead of inflicting injury by reducing sales they often tend to advertise and to increase the sales of the original photographs.

"The committee had earnestly protested against the proposed changes in the law affecting the copyright of photographs, especially against amendments, 'which in effect increase the already excessive penalties for the infringement, unintentional or wilful, of photographic copyright.' And the committee had proposed, in order to bring matters to a focus, that, if any alterations in the photographic copyright law were made, an amendment should be adopted as follows: 'Provided, however, that the reproduction of a photograph in any newspaper by the process known as stereotyping shall not be construed as an infringement of the copyright of such photograph.'

"This amendment raised the broad question whether the newspaper reproduction of a photograph should be viewed as a damaging, punishable infringement of copyright. While the congressional joint committee was unwilling to take the radical position that a photograph should not be protected by the copyright law against any reproduction, even by inferior processes, it was willing to accept that such infringements were not to be justly classed as precisely the same footing with photographic infringing copies of photographs and were not to be justly punished by the infliction of an arbitrary minimum penalty indiscriminately applied. In recognition of this fact, the joint congressional committee eliminated the arbitrary minimum penalty, and left the matter of equitable damages in each case to the discretion of the court, so that if justice suggested it an assessment of even one cent damages might be made.

"Newspaper reproduction, whether authorised or unauthorised, has no tendency to reduce sales of the original photographs; rather to increase them. The injury, if any, done to the copyright proprietor is the unjust withholding from him of the small sum customarily paid by the newspapers for consent to use a copyrighted pho-

This injury is not increased or diminished in accordance with the number of copies issued by the offending newspaper.

The damages in the two cases are on an entirely different basis, the measure of damages which is appropriate in one should not, in the nature of a suggestion to the court in the exercise of its discretion, be applied to the other. For this reason there should, in the committee's opinion, be added to Sec. 19 (b) Fourth of the Copyright Bill, an amendment providing in substance that the measure of damages, here suggested, shall not be applied in the case of damages for infringements by newspapers through the reproduction or imitation in their columns of copyrighted photographs.

The American newspapers using in regular course of business large numbers of illustrations every day, and for this purpose crudely tracing or hastily modifying and adapting many photographs, frightened as well as copyrighted, are especially liable to be guilty of unintentional infringements. It is urged that, in justice to the newspapers, notice of the fact of copyright in the case of a photograph should be made even more conspicuous than the existing law provides, and that such notice, to be effective, should extend to authorised reproductions of copyrighted photographs in newspapers elsewhere.

The Copyright Bills, however, reduce instead of enlarging the legal requirements of this notice, classing photographs in this connection with works of art upon which the copyright notice is as an objectionable disfigurement. The existing law requires the copyright (date) by A. B. shall be inscribed 'upon some visible part of the photograph, or of the substance on which the same

shall be mounted.' The proposed law requires, in the case of a photograph, only the letter C within a circle, accompanied by the initials, monogram, mark, or symbol of the copyright proprietor, 'provided that on some accessible portion of such copies or of the margin back . . . or of the substance on which such copies shall be mounted, his name shall appear.'

"To cause the newspaper reproduction of a photograph to be classed as an infringement, and to reduce to a minimum unintentional infringements, the fullest warning of the fact of copyright should be given to the newspapers. If a photograph is to be protected against such reproduction, it should be classed among works of art, upon the margin, or back, or mount, of which a simplified notice of copyright may be hidden, but should bear the copyright warning conspicuously on the photographic print itself, and upon every authorised reproduction of it."

The committee think that the provision of the new law punishing infringement with fine or imprisonment, or both, is too severe. It is recommended that for the present the amendments already suggested be urged (1) requiring notice of copyright to appear distinctly on the face of the photograph, to give protection against newspaper reproduction, and also to appear on every authorised reproduction of a copyright photograph; (2) excepting newspaper reproductions of photographs for the measure of damages (\$— for every infringing copy up to 5,000), suggested in the assessment of damages for other infringements of photographic copyright; and (3) either excepting infringements of photographic copyright by newspaper reproduction from criminal prosecution under Section 21. Senate Bill (Section 22, House Bill), or eliminating that section altogether.

## NOTES ON INTENSIFIERS AND REDUCERS.

Upon Mr. A. J. Garwood, read before the Edinburgh Photographic Society, many useful hints were communicated as the result of the author's own experience in the use of the modern intensifier. In default of space for the full text of the paper we extract the points brought forward by Mr. Garwood:—

Bleaching agent usually employed in mercurial processes is bichloride of mercury. I notice that most of the published recipes for this give a saturated solution of the salt for the purpose. In my opinion, is open to the objection that there is always a risk of undissolved particles of the salt being carried over and on the plate, and if these are not immediately removed, spots, more or less opaque, at others transparent, will occur. Personally, I use the following formula, which is one I can with every confidence recommend—viz., bromide of potassium, 100 grains; bichloride of mercury, 100 grains; water, pure, 10 ounces. The mixture should be used to assist solution, and it should then be filtered. The result is a clear, colourless liquid, which will keep for years, and with occasional filtration, be used over and over again.

### The Piper-Carnegie Chromium Process.

This process does away with what I have often heard fellow-workers express their great dislike to—namely, the poisonous nature of the solutions used in mercurial intensification. I thought it worth while to take the matter up, especially as the process is said to offer certain other advantages over most of the mercurial processes, one of these being its close analogy to the mercury-ferrous process, in what I may term its cumulative action.

I started experimenting at once, but for a long time was quite unsuccessful, for, although I got the intensification all right, I could not get the films on the plates. It seemed, in fact, to be a perfect process, no matter what redeveloper or what modification of the author's formula I tried. After working away for some five months in this manner some lucky chance, for quite another purpose, led me to get some amidol. I had up to this time never used this reagent, but on trying it for the intensification experiments, I was successful, and have not had a single failure by frilling of the film. Apparently the same thing must have troubled the author in a subsequent article they state that, for the redeveloper they recommend amidol in preference to any other. As

to the permanency of the results, I can only say that negatives intensified by the method in December, 1904, certainly showed no signs of fading or other change. The operations are exceedingly simple, and, from my own experience of the process, I think it entitled to a very high place among intensification methods.

### The Persulphate Reducer.

I look upon persulphate as one of the most useful salts that have been introduced to the photographic public of late years, but unfortunately its action is inclined to be erratic.

There is no doubt that the best time to use it is immediately after the final washing of the negative, and before it has been allowed to dry. Failing this, the negative must be thoroughly soaked in water, for, above all things, it is necessary that the negative be thoroughly and uniformly wet before this reducer is applied. In treating old negatives it is advisable to give them a thorough cleaning in an ammonia bath, followed by a prolonged soaking in water. As a matter of fact, this treatment will do no harm, whether the negatives be old or new. The negative should be carefully examined for fog and any traces of it removed, for it is one of the peculiarities of this reducer that it has a great tendency to leave fog alone, and to this fact is due, in my opinion, some of its apparently irregular action. I have used this reducer ever since its introduction, and perhaps a few further hints may not be out of place.

It is far better to err on the side of a weak bath than on a strong one, and in this connection I find that different makes of the salt are by no means uniform, and that what would be a weak bath with one would be a fairly strong one with another. The tabloids of Burroughs, Wellcome, and Co., I have found both uniform and convenient, and for a long time I have used nothing else. For general work I use one tabloid to an ounce and a half or two ounces of water. If this is found too weak the bath is easily strengthened by the addition of another tabloid, or even a portion of one. Care should be taken that the salt is completely dissolved before applying the solution to the plate, as if any undissolved particles settle on it they invariably cause very ugly star-like markings on the plate, which are practically impossible to get rid of. This precaution applies, of course, to any make of the salt.

The careful addition of a few drops of sulphuric acid to the bath undoubtedly has the effect of making it more regular in its action. This reducer acts slowly at first, but soon quickens. The dish should

be gently rocked, and the action carefully watched. When on looking through the plate it appears to be sufficiently reduced it should be quickly placed in a 10 per cent. solution of soda sulphite, which at once stops further action. The plate should not be removed from the sulphite solution too soon, five minutes being the minimum. As in the case of the previous reducer, it is, of course, advisable not to go too far, as the process can be repeated if necessary; but should one go just a little too far the application of one of the intensification methods will frequently restore the negative. Some workers recommend that, in addition to the sulphite bath, the plate, after a few minutes' washing, be placed in a clean hypo bath for five minutes or so. The final washing in either case must be thorough.

#### Sanzol Reducer.

Another reducer, a comparatively recent introduction, the makers of which claim for it a similar selective action on the high-lights of a negative to that possessed by ammonium persulphate, is known by the name of sanzol. It is a heavyish yellow powder, which dissolves fairly well in water. The dose, as recommended by the makers, is two grains of the salt to an ounce of water, to which is added fourteen

drops of pure nitric acid. The solution is poured over the plate the dish well rocked until the plate is sufficiently reduced, which should be placed in a bath consisting of fourteen drops of 88° ammonia to the ounce of water, in order to clear it. Allow remain in this bath for three minutes, and then give a final wash fifteen minutes in running water. My experience of this ammonia is that it causes frilling of the plate, and that it is better to use it altogether, or, at any rate, not to apply it until some of the ammonia has been washed out of the plate. The results I have been able to obtain with this reducer are certainly encouraging, and as my experience so far has only been with plates, I look forward to further experiment with it in connection with bromide and gaslight plates for treatment of which it is also recommended by the maker. It appears to me to show much the same tendency to neglect localities as does ammonium persulphate.

As in the previous case, I strongly advise the thorough rocking of the plate before applying this reducer, and I also recommend the use of a soft camel-hair mop instead of rocking the plate. A sediment or scum settles on the plate, which is much easier to remove with a mop.

## THE ISOSTIGMAR LENS AND THE PETZVAL CONDITION

[The following is the conclusion of the paper by Messrs Horace C. and Conrad Beck before the Royal Photographic Society. Next week we hope to publish the interesting discussion promoted by Messrs. Beck's contention as to the invalidity of the Petzval condition in determining the quality of a flat-field anastigmat.]

LET us now consider what happens to these corrections when the central focal errors have been corrected, but the equivalent planes are not superimposed, as shown in Fig. 4. It is well known that the size of the image depends upon the equivalent focal length of a lens, and if we were to examine the whole image of an object, and not only its exact centre, we should find that, although the rays parallel to the axis which pass through any part of the lens meet at a point on the axis, a bundle of oblique rays do not meet at any one point, because the equivalent focal length of the rays passing through the centre of the lens is AB, and the equivalent focal length of the rays passing through the edge of the lens is DB, and the edge rays having a longer focal length will produce a larger picture than the centre rays, as indicated by the two arrows at B. To make this clearer, let

Fig. 5.

us look at Fig. 5a. For simplicity the lenses are omitted, but the lines A and D represent the positions of the equivalent points for the central and edge rays respectively. This shows the way in which the same lens system forms an image. The bundles of oblique rays (E, Fig. 5a) which come from the edge of the lens will form a picture of an infinitely distant object at a point K, whilst those coming through the centre of the lens (C, Fig. 5a) will form an image at the point L, the rays between the centre and the edge filling up the intermediate positions in the image. Now if we place a ground glass at the image point KL, a comet-shape appearance, as shown by the side of the diagram, will be seen. This is known as coma, or unsymmetrical oblique spherical aberration, and is due to the fact

that the equivalent planes for the different rays do not coincide. Again, if we take the case where the equivalent planes coincide, the oblique focal corrections are not made, the oblique rays (Fig. 5b) going through the edge of the lens come to the point K, while those going through the centre of the lens C (Fig. 5c) come to the point L, but the angular size of the image will be constant, and if we examine the image on a ground glass at the point we shall find that it appears as a spot with a misty circular surround. This is called symmetrical oblique spherical aberration.

We will now demonstrate practically upon the screen the effect of a lens in which the equivalent points corresponding to different zones of the lens are widely separated. This is the lens system that is illustrated in Fig. 4d and in Fig. 5b.

Our object consists of three small points of light, one of which is exactly in the optic axis, and it will be observed that the image of this point is well defined and circular, the other two points, which are equi-distant on either side, show as two comet-shaped images, proving that the light that is passing obliquely through the lens is not brought to one point.

We will now insert a small prism over the central portion of the lens, and will adjust it so as to throw the central light to a position on the screen than the marginal light. This shows that the marginal rays have considerably more magnifying power than the central ones, for, although the two images of the object on the optic axis are above one another, the images of the object on either side of the axis do not occupy similar positions.

A second method of demonstrating this is by swinging the lens. It is well known that if a lens be swung on its back equivalent plane the image will remain stationary. With this lens, if we swing it on the equivalent plane of the central rays, you will observe that the image formed by these rays will remain stationary, whilst the other image moves rapidly.

#### Colour Corrections of Opaque Rays.

Now, in correcting a photographic lens it is very important to get these two errors as small as possible, but, provided both have been corrected, we still find that the same thing may occur with reference to the colour-corrections. The red and blue rays meet at the same point on the axis, that is, the focus correction must be made, and the equivalent planes for the red, blue, and green rays must be in the same place, or the size of the images formed by the different coloured light will be different.

Take the case first when the equivalent planes for the two colours are in different positions. As before the size of any object upon the plate will depend upon the equivalent focal length. In this case

magnification for the red rays is considerably more than that of the blue, and therefore the red light from a point of white light at an angle will come to the point K (Fig. 6a), while the blue light will come to the point L, and if we place a screen at KL we see a spectrum of colours as shown on the side of the diagram. Again, if we take the case in which the principal planes for the two colours are superposed, but the focal plane of the blue light is at M, Fig. 6b, while the focal plane of the red light is at N, the red light comes to K, and the blue light to L. The image examined at the

Fig. 6.

point L shows a brilliant central spot with a large fringe of red round it. This latter error in the oblique colour correction, Fig. 6b, will generally be approximately corrected, provided the axial colour correction and the spherical aberration are correct, but the former case of the unequal magnifications of the blue and the red images is a separate matter requiring a special construction for its elimination. It is met with in an exaggerated form in some combinations of lenses separated by large intervals.

We have here a lens which shows the error in a marked manner in the screen. It, in practice, has the effect of showing a black dot on a bright field, as a dark band fringed with red on one side and blue on the other.

**Distortion.**

There is also the possibility that the equivalent points may not be in the same position for the central that they are in for the oblique rays. In this case the size of the image produced by the rays going through the lens at a great angle is different to that produced by those coming at a small angle. This gives the well-known defect of distortion, and it depends as to whether the size of the image produced by the oblique rays is greater or less than that produced by the axial rays, as to whether the distortion of what is known as incushioned or barrel-shaped. The aberration called astigmatism is produced, as you are doubtless aware, by the fact that a bundle

of rays impinging upon a spherical surface in a direction that is not towards the centre of the surface will have presented to it a different curvature in different meridians. The rays in the plane which also cuts the centre of curvature will meet a differently curved surface to those which are in the plane at right angles, and therefore, in Fig. 7, whilst the light in the plane of paper is focussed

Fig. 7.

to the point A, the light at right angles to it is focussed to the point B, and consequently a vertical line instead of a point will be formed at B, whilst a horizontal line will be formed at A. It is in connection with the overcoming of this special defect, and at the same time keeping the image formed by the lens upon a flat field, that the so-called Petzval condition has been advanced, as being the only method by which such a correction could be made.

It will be seen, therefore, that the chief oblique errors which have to be corrected are astigmatism, symmetrical and unsymmetrical spherical aberration, regular chromatic aberration, unequal magnifications of different coloured images, and distortion. We are glad to say that in the design of this lens all these errors have been largely eliminated, in fact, as you will see from this slide, the definition is practically equal over the whole of the angle of view. This photograph is taken of two of our test charts placed side by side and photographed by a 4½-inch lens upon a 1/1 plate. The strip of the 1/1 plate is then cut off and is slid through the lantern. It was taken with full aperture *f*/5.8, and the size of the quarter-plate which it is supposed to cover, is marked on the slide, and also the various angles which different parts of the picture represent.

**The Commercial Form of the New Lens.**

We are at present putting this lens upon the market in two series, one at *f*/5.8 and the other at *f*/7.7. They are adapted for all classes of work, and for landscapes or long focus portraiture they have the advantage that the half combinations can be used as single lenses, which, with moderate stops, give good results on the size plate for which the complete lens is intended. These half combinations are of very convenient foci, the front and back of a 7½-inch complete lens having a focus of 11 inches and 15½ inches respectively. In this way each lens is a three-focus lens.

We should like to take this opportunity of expressing our thanks to Mr. Victor J. Poole, one of the members of our staff, for his able assistance in the working out of this lens.

HORACE C. BECK.  
CONRAD BECK.

COURT PHOTOGRAPHER.—Mr. Rose had a curious prisoner before him at the Tower Bridge Police Court last week. This was Alfred Ward, a bookseller's assistant, of Tenda Road, Bermondsey, who was charged with being disorderly at Southwark Park Road. Before being brought into court the prisoner requested to see the "court photographer," as he thought it absolutely necessary to have his photograph taken before and after being in the dock.

THE KING AND PHOTOGRAPHERS.—It is not often that the King attracts himself to the attentions of the snapshotter, but on Thursday His Majesty did so with a good grace at the Sicilian town of Taormina. The Archbishop there is an enthusiastic amateur, and had the privilege of photographing King Edward, the Queen, and Princess Alexandra, who had motored over to see the cathedral. Queen Alexandra retaliated, and took away a likeness of his Eminence.

BLACKMAIL BY PHOTOGRAPH.—"I am madly in love with you. But you are poor; you are rich." Thus wrote Joseph Morris, alias Marshall, in the month of nineteen, to the daughter of a prominent merchant in

Bristol. He stated further that he had taken a photograph of her which, if published, would make her ridiculous, and that a reply should be sent to a certain address. A "dummy" answer was sent, and when Morris went to receive it he was arrested. At the local police court on Saturday he was sentenced to six months' hard labour in default of finding sureties for his good behaviour.

IRISH INTERNATIONAL EXHIBITION, 1907.—An international exhibition is to be held in Dublin during the present year, and for this purpose spacious buildings are in course of erection in Herbert Park. Photography will be included in the fine arts section, which will consist of a collection of modern art of (1) Ireland, (2) Great Britain, and (3) other countries. The exhibits will be divided into 19 sections, in which the arts, industries, and manufactures—not only of Ireland, but of all other nations, are to receive a place. Promises of substantial support from many foreign countries have been received, and from particulars to hand the exhibition, which is announced to be opened in May, seems to be assured.

## Exhibitions.

### THE CLEVELAND GUILD.

THROUGH the agency of the multitudinous photographic societies throughout the country, photographers, both professional and amateur, have both the technical and social aspects of things well attended to. Well-organised society demonstrations and papers, on the right soil, create a desire for emulation to a degree not possible to the mere reader of handbooks and journals. Yet the sister arts of printing, lithography, and similar crafts (with exceptions in three or four of the largest cities) are not so favoured. True, there are the trade unions for the various operators, and federations of employers, but these exist almost exclusively for the maintenance of wages and prices, and do not interest themselves so much as they might in the science and technique of their craft.

In the unique constitution of that young and vigorous body, the Cleveland Guild of Printers, we find much that the major body of professional photographers and their employees might well imitate. This especially applies to the "principle" of the Guild, which is that—

"The Guild affirms the principle that the production of good work should be the life purpose of every man, and that such purpose should be diligently pursued by the members of the Guild to the best of their ability."

The object of this new Guild is not solely that of producing good work, but also a feeling of good fellowship among all its members, both employers and employed; and this latter object has been achieved to an extent scarcely to be hoped by the one or two keen enthusiasts responsible for its inception.

To mark the close of the first session, the Cleveland Guild held an exhibition in the Co-operative Hall, Middlesbrough, last Friday and Saturday. Among the interesting things there shown was the competitive work of the various members of the Guild in the departments of design, photo-engraving, bookbinding, fine letterpress and lithographic printing. The respective judges were Mr. R. G. Hatton, Armstrong College, Newcastle; Mr. A. J. Newton, L.C.C. School of Photo Engraving, Bolt Court; Messrs. W. Hale (Stockton), and Baker Hudson (Middlesbrough; and Mr. A. J. Appleyard (Middlesbrough).

Fine examples of old and rare bookwork were shown, the Middlesbrough Corporation having lent a large and valuable collection, besides which there were lent some fine volumes from the private collections of one or two local bibliophiles.

The influence which photography now has in the graphic arts, even in local work, was markedly shown in the many fine specimens the printers had displayed at their stalls, the more notable being those of Messrs. Appleyard (Middlesbrough) and Mr. John Harrison (Stockton). Messrs. Penrose and Co. (London) showed three-colour appliances and examples of their "Nickello" moulds, and half-tone stereotypes formed a strong centre of interest to many of the master printers.

Among the exhibits were a number by Messrs. Hood and Co., Ltd., the well-known photo-engravers and printers, of St. Bride Works, Middlesbrough. These included actual half-tone blocks as prepared for postcard printing, and examples of line zinc blocks in the various stages of manufacture. The exhibit also included an interesting collection of rough and finished sketches for reproduction in colour.

The exhibition was opened by the Mayor of Middlesbrough (supported by the chief magistrate of the neighbouring borough of Stockton), who wished that the present might be the forerunner of many similarly successful exhibitions

**PROCESS INSTRUCTION IN MANCHESTER.**—Two courses of instruction are just commencing in the photographic and printing department of the Manchester Municipal School of Technology. The first is a course of eight lectures by the principal of the department, Mr. Charles W. Gamble, on "Photographic Colour Processes." The lectures will be fully illustrated by means of practical demonstrations and by examples of the processes and methods described. The second is a course of eight lessons in intaglio photo-mechanical methods by Mr. R. B. Fishenden. The fee for the first is 2s. 6d.; for the second, 5s.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents were made between April and April 20:—

**CAMERAS.**—No. 8,678. Improved camera. Henry Wood, 13, Linhope Street, St. Marylebone, London.

**SPECTROGRAPHIC APPARATUS.**—No. 8,723. Apparatus for producing on photographic plates or the like images consisting of many small parts in close contiguity to one another and decomposed into the colours of the spectrum. Franz Urban, 56, Ludgate Hill, London.

**TELEPHOTOGRAPHY.**—No. 8,727. Improved methods of telegraphically transmitting photographs and the like and system therefor. Arthur Korn, 173, Fleet Street, London.

**PRINTING APPARATUS.**—No. 8,817. Improvements in photographic printing apparatus. James Warry Vickers, Finsbury Square Buildings, London.

**PRINTING FRAME.**—No. 8,896. Combination photo printing frame. Leonard Arthur Waldron, 46, Distillery Street, Norwich, Norfolk.

**MULTIPLE PHOTOGRAPHY.**—No. 8,957. Multiple device for photographing. James Beckett Shaw, 91, Blantyre Road, Liverpool.

**SHUTTERS.**—No. 9,039. Improvements in shutters for signalling, photographic, philosophical, and like purposes. Arthur James Carter, 6, Lord Street, Liverpool.

**MOUNTANTS.**—No. 9,105. Paste for mounting photographs, prints, pictures, maps, or diagrams, or the like. George Richard Holding, 62, Caversham Road, Kentish Town, London.

**DAMPING.**—No. 9,115. Improved means for damping one surface to another, especially applicable in photographic cameras. Louis Gandolfi, 185, Fleet Street, London.

**LANTERN PROJECTION.**—No. 9,246. Improvements in or connected with means for displaying photographic or other pictures or the like by the aid of a lantern or otherwise. Alfred Clarke, Birkbeck Bank Chambers, Southampton Buildings, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**CYLINDER PRINTING MACHINES.**—No. 24,851. 1906. The invention relates to a continuous printing machine, in which a drum A is mounted in the frame B, and adapted to be rotated. The drum A is covered with flexible material, and rotates, carrying with it the tracing and photographic paper, in close contact with the concave surface of a glass plate C, fixedly mounted in the frame B. The glass plate C may be made as a semi-cylinder, as shown

Fig. 1.

Fig. 2.

in Fig. 1, fitted in suitable end frames, or it may be made as a section of a cylinder, less than a semi-cylinder, as shown in Fig. 2, and provided with extension pieces c, which act as guides for the tracing and photographic paper carried around by the drum A.

In work, the tracing and photographic paper are fed, over the feed table D, between the glass C and the periphery of the

rotating drum A, and carried therewith in close contact with the glass C, the drum being revolved at a speed in proportion to the exposure required. The friction between the glass and the tracing being less than that between the tracing and the photographic paper there is no relative movement between the photographic paper and the tracing and the drum carries these two round without the use of any adhesive. Benjamin James Hall, 1, Castlenau, Barnes.

ops.—No. 15,674. 1906. Each leg of the tripod is provided with a thin metal plate, so shaped and pivoted to the upper end of the leg that it can be folded into the leg or turned upwards to combine with the plates on the other legs to form the block for the camera or other object. The plates are provided with corrugations, pins, and holes, or similar means for holding the plates and legs in their proper relative positions, and such means may be arranged to hold the plates and legs and allow the size of the block being varied. The plates may be connected together by the screw used for attaching the object to the block, or by separate fastenings.

Fig. 1.

In the arrangement shown in the drawings the top for the tripod stand consists of three metal plates, *a*, *b*, and *c*, each of which is provided with a pair of lugs *d*, by which the plates are pivoted to the tops of the legs, so that they can be folded on the legs or be opened out to form the complete top. The lower plate *a* is provided with a hollow pin *e*, which has a head and the opposite sides of this head are cut away, as shown in Fig. 1. The centre plate, *b*, has a hole of the same size and shape as the head *f* of the pin *e*, and the top plate *c* is made with a slot *g*, which is enlarged at one end to pass over the head of the pin *e*. The plates are all corrugated in the direction of the length of the top plate *c*, so that when the three plates are together as shown there can be no movement of one plate relatively to the others in a direction at right angles to the length of the plate *c*.

Fig. 2.

With a tripod stand fitted with a top of the kind herein described, the hole in the plate *b* is passed over the pin *e*, and this pin and the corrugations the plates are held from moving relatively to each other. The plate *c* is then placed in position over the pin *e*, and pulled forward in any desired position in slot *g*, when the head of the pin *e* prevents the three plates from coming apart. The camera can then be placed in position and fixed by a screw passed through the hollow pin *e*. When improved top is to be used for cameras fitted with a turning ring, the ends of the plates *a*, *b*, and *c*, are placed in the turning ring and the three plates are securely fastened together by a bolt, which is passed through the pin *e*, and has a head

recessed on its underside to cover the head *f* and grip the plates. The clipping bolt may be used whenever it is desired to firmly fasten the plates together, and it may be hollow or tapped to allow of a camera or other object being attached by a screw. Leon Faure, trading as Gay and Co., Bridlesmith Gate, Nottingham.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### "Watalu" Self Developing Plates.

Testing a "Watalu" (says a writer in "The Photographic Monthly") against a "Wellington" unbacked plate of the same variety, we found halation entirely absent from the negative of a candle-flame on the former; the unbacked plate, with the same exposure, and developed for the same time in developer dissolved from a "Watalu," showing it distinctly. Eighteenpence per dozen quarter-plates, therefore, does not seem too much to pay for backed plates and developer, especially as we cannot find that their advantages are obtained at the cost of lessened efficiency in any way.

### A Backing Test.

In selecting a backing (says Mr. W. H. Glaser, in "The Practical and Pictorial Photographer") few photographers consider optical characteristics, and fewer still submit the chosen products to any test except that of actual work. No better test could be desired as a final criterion provided the comparisons be made under identical conditions for all the brands tested; yet how often are such conditions convenient, or even possible, to secure? But the most important optical characteristic can be examined by a simple and easy experiment, which can be carried out in the work-room in less than one minute, with no other apparatus than the ground glass screen belonging to the camera. Smear a little of the backing on the rough side of the screen, and rub it well in with the finger tip, until the patch is translucent. The more perfect the backing the more transparent will the patch be. Remember the distinction that a translucent body is one which merely transmits light, whereas a transparent body is one through which objects can be distinctly seen.

### Photographing Running Matches.

RUNNING photographs (says Mr. Adolphe Abrahams in "The Photographic News") need a focal-plane shutter unless you stand a very long way from the subject, in which case the figures will be undesirably small. It must be remembered that movements of limbs—I might almost add of features too—as well as forward velocity have to be considered. The hundred yards should receive 1-400 to 1-1,000 sec. according to proximity. The finish of a long race does not need a briefer exposure than 1-250 sec. If you have to stand in the crowd a long focus lens is of great service. When photographing at Queen's Club, or at the Championship meeting, I use the back combination of my Zeiss lens (14in. focus), and with an exposure of 1-400 sec. at *f*/12.6 have been able to secure sufficiently full exposures on fairly well-lighted subjects in late March.

## New Materials.

"Auto" Self-toning Paper. Made by Drs. Lüttke and Arndt, 8, Zollstrasse, Wandsbek, Germany.

In availing ourselves of an opportunity of making a trial of this self-toning P.O.P., we selected a variety of negatives, both portrait and landscape, the results from which on the paper entirely satisfied us as to the latter's suitability for various classes of work. "Auto" is a collodion paper obtainable in one glossy surface (mauve), three matts (mauve, chamois, and white), and one rough surface. In the case of the three of these varieties, which came under our notice we found it necessary to overprint to just the same extent as with ordinary P.O.P. The simplest form of treatment is the use of a hypo bath of 2oz. to the pint, in which the prints, after a preliminary washing, are tone-fixed for 10 to 15 minutes. It was satisfactory to find that this toning action took place energetically when the bath was, as advised, in an alkaline condition, and when, as we have just said, the prints were freed from free acid by a

preliminary wash. Such conditions are chemically right, and the toning action which takes place under them should assure the permanence of the results. The hypo solution is made alkaline with a little carbonate of soda, and the tone obtained in the solution thus constituted is a pleasing brown.

Substituting a 10-minute treatment in a 2 per cent. salt solution for the first wash, the tone in our experience was more purple, although the makers give it as redder, but for a rich purple the so-called "photographic" tone, the prints are treated for five or ten minutes—the lesser time for fresh paper—in the following:—

Sodium acetate .....	1oz.
Ammonium sulpho-cyanide .....	1oz.
Sodium chloride .....	1oz.
Distilled water .....	50gs.

As regards its mechanical properties, the "Auto" shows every sign of being a collodion paper of high quality. It exhibits no inconvenient curling propensities, and is not easily caused to crack. It is issued in the regular English sizes, as well as in a quality of heavier weight, fitted as regards both size and substance for postcards. For samples and particulars of the prices, application should be made to the makers at the address given in the advertisement pages.

"Bordalace" Mounts. Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, W.

Quite a novelty in mounts is offered by the firm of Fallowfield in these mounts, the essential feature of which is the series of circular holes which forms a border to the card. The holes permit of ribbon

of different colours being used in great variety, and, as a result, impart to the mounts a very attractive appearance. Not only this but the method affords numerous means of lacing mounts together in series. It is easy to see how any wall space, however large, might be covered with photographs on "Bordalace" mounts, while requiring

only the uppermost row to be attached to the wall. The price of the mounts is low. For prints up to quarter-plate it is 4s. per 100, 35s. per 1,000. For those up to  $5\frac{1}{2} \times 3\frac{3}{4}$  it is 6s. per 100, 35s. per 1,000. A smaller size is made for prints up to  $3 \times 2$  inches at 3s. per 100, or 25s. per 1,000. The novelty is one which both dealers and professional photographers should find a ready source of business.

THE "ENSIGN" ROLL FILM MONTHLY NEGATIVE COMPETITION.—Messrs. Houghtons, Ltd., are offering a monthly prize of a three-guinea "Holborn-Ilex" quarter-plate hand magazine camera and a packet of "Ensign" flat cut films for the best and most striking negative taken on an "Ensign" roll film. Each entry must consist of a negative and contact print from it, accompanied by an entry form, which may be obtained from any dealer, or direct from Messrs. Houghtons, Ltd., 88 and 89, High Holborn, London, W.C.

## CATALOGUES AND TRADE NOTICES.

"GOLDONA" POSTCARDS.—Messrs. Griffin deserve the thanks of photographers for the laughs they promise to arouse by means of series of picture-postcards illustrating photography in the stone age. The cards call attention to the virtue of "Goldona."

MESSRS. WELLINGTON AND WARD have issued a booklet entitled "Notes on the Use of the Wellington 'Watalu' Self-Developing Plates," which presents the necessarily scanty instructions for the use of that new product. It contains two examples of the powers of the plate in the shape of "Wellington Carbon Bromide" prints from "Watalu" negatives.

MESSRS. TURNER AND CO., Exchange Street, Blackburn, send an illustrated circular of the "Cosway" background which they have ready. The circular includes a large reproduction of the background, and may be had gratis from Messrs. Turner. One may mention that the firm, which has specialised with success in backgrounds of all kinds, is enlarging its borders, having opened premises at Kingston Place, Blackburn.

MESSRS. W. BUTCHER AND SONS have issued a little booklet containing a full list of their popular "Primus" specialties, a copy of which will be sent free to all applicants on receipt of postcard addressed to the above firm at Camera House, Farringdon Avenue, London, E.C. Messrs. Butcher and Sons will also be pleased to send a supply to any photographic dealer for free distribution to the counter.

MESSRS. O. SICHEL AND CO., of 52, Bunhill Row, London, E.C., have issued a list of the goods manufactured by them, or for which they are wholesale agents, for the special use of professional photographers to whom they are now mailing copies. The list contains illustrations and particulars of all the apparatus and accessories needed for studio work, including a large variety of background chairs, benches, etc., and is well worth a careful perusal. Messrs. Sichel will be glad to send a copy to any professional photographer who has not yet received one on receipt of trade card.

MESSRS. ROMANET AND GUILBERT, whose London address is Red Lion Square, W.C., send us a copy of their 1907 catalogue of photographic apparatus and accessories, a considerable portion of which is devoted to the description and illustration of their "Argus" cameras, to which some new features have been recently added. A variety of telescopic metal tripods at very reasonable prices are also worthy of special attention.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, MAY 4.

North Middlesex Photographic Society. Outing to Ashted.  
Aberdeen Photo Art Club. Outing to Edzell.  
Hull Photographic Society. Outing to Farnington.  
Chelsea and District Photographic Society. Outing to Perivale.  
Borough Polytechnic Photographic Society. Outing to Loughton.  
Handsworth Photographic Society. Outing to Salford Priors.  
Edmonton and District Photographic Society. Outing to Wanstead Park.

#### MONDAY, MAY 6.

Bowes Park and District Photographic Society. "Stereoscopic Photography." H. A. Miles.

#### TUESDAY, MAY 7.

Royal Photographic Society. "Dry Collodion Plates with Preservative." J. Watson.  
Sheffield Photographic Society. Practical Demonstration. J. Gilbert Jackson.  
Rotherham Photographic Society. "Buying and Using a Camera." J. W. Stas.  
Hackney Photographic Society. "Results on S.C.P. Lantern Plates and Papers."  
Handsworth Photographic Society. Council Meeting.

#### WEDNESDAY, MAY 8.

Hampstead Scientific Society. Members' Print Competition.  
Edmonton and District Photographic Society. "Re-touching." Mr. Vince.  
Competition, April 20, Prints.  
Workshop and District Photographic Society. "Theory and Practice of Self-Toning Papers." John J. Griffin & Sons.  
Croydon Camera Club. "Hand Cameras." The President.  
Central Technical College Photographic Society. "The Cinematograph." N. M. Clougher.  
North Middlesex Photographic Society. "Copying." S. H. Bentley.

#### THURSDAY, MAY 9.

Handsworth Photographic Society. "The Carbon Process." R. J. Pummell.  
Richmond Camera Club. Annual General Meeting.  
North London Photographic Society. Members' Lantern Slide Evening.  
Kettering Camera Club. "Theory and Practice of Self-Toning Papers." John J. Griffin & Sons.

## ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held April 30, Mr. Leslie Selby in the chair. A lecture, entitled "With a Hand Camera to the Niagara Falls," by Mr. H. O. Klein, was read by the secretary, Mr. J. McIntosh, in the unavoidable absence of Mr. Klein, and was much enjoyed by an interested audience.

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—At the eleventh hour it was decided to hold the opening meeting of this new society at Avenue House, Lewisham, where there was a large room available, than at the society's headquarters, 75, High Street, Lewisham. The result justified the move, for about 150 members and photographic friends managed to squeeze themselves in to hear Mr. F. J. Mortimer's lecture on "Marine Photography," while a number who came late were unable to obtain admission, and a party of men who failed to find room in front stored themselves away behind the screen. A resolution was enthusiastically adopted approving the action of the organising committee in establishing the society, with a rider instructing the executive committee to appoint an advisory committee of ladies, with Mrs. Bennetto as lady secretary, to look after the interests of the lady members. This is a novelty in photographic circles, and we shall watch the result with interest. Mr. F. J. Mortimer, F.R.P.S., was elected president for the year, and amongst the vice-presidents elected were the Mayors of Lewisham and Deptford, Major E. F. Coates, M.P. for Lewisham, the Vicar of Lewisham, Canon Barnes-Lawrence, and Messrs. W. W. Bryant, F.R.A.S. (Royal Observatory), A. Haddon, T. K. Grant, F.R.P.S., P. R. Salmon, F.R.P.S., C. Winthrop Somerville, F.R.P.S., W. Calder Marshall, F.C.A., and C. Welborne Piper, A.R.I.B.A. Mr. J. Nixon, of Ingle-side Grove, Blackheath, who was hon. secretary to the organising committee, was appointed hon. secretary and treasurer to the society, with Mr. G. W. Andrew, of 12, Old Dover Road, as joint hon. secretary, to look after the portfolio, which is to have a prominent place in the society's programme. Communications were received from Mr. Horsley Hinton, the editor of "Focus," Rev. F. C. Lambert, and others, wishing success to the new venture.

## Commercial &amp; Legal Intelligence.

**RAPID PHOTOGRAPHY.**—Sitting at the Brighton County Court, last week, his Honour Judge Scully had before him a case in which De Jorrette Plummer, 59, King's Road, Brighton, rapid art photographer, sued Isaac Mindel, of Herman's Studio, Whitechapel Road, London, photographer's assistant, for £16 damages sustained by an alleged breach of agreement, by reason of the defendant leaving plaintiff's service without giving two months' notice. There was a counterclaim of £3 6s. 2d. for commission, travelling expenses, etc.

Mr. Rowland Harker, barrister, who appeared for the plaintiff, said the fact of defendant's leaving without notice was not disputed, and he thought the real fight would be on the counterclaim.

Plaintiff said he made a specialty of rapid art photography, taking and finishing photographs "while you wait." When defendant entered his employ in July last year he represented his age as twenty-five. His wages were first 30s., and afterwards £2 a week and commission. Until he left in December he had the run of the dark rooms, and was enlightened as to witness's patent processes. In October he was sent to the Southampton branch, and in December was instructed to go to the Portsmouth branch, but, instead of doing so, he left without giving the two months' notice specified in the agreement. Nothing was due to defendant for commission, and he knew nothing about his claim for travelling expenses.

For the defence, defendant's solicitor, Mr. C. H. Downes, put his client in the box. Defendant said he was only twenty when he entered the plaintiff's employ and signed the agreement, and he denied that he represented himself as twenty-five.

Cross-examined, he said he left plaintiff's employ because he was not paid. He admitted, however, that he had charge of the cash at the Southampton branch, and had instructions to take his wages out of it. After he had left, plaintiff saw him in London, and paid him £2 for wages due to him.

Mr. Downes asked his Honour to hold that at the time defendant entered into the agreement he was an infant, and that the agreement was void.

Questioned on the counterclaim, defendant said 2½ per cent. commission on £50 or £60 was due to him, and a sovereign or 25s. for travelling expenses.

Dealing with the point of law raised on the agreement, Mr. Rowland Harker pointed out that plaintiff was not asking for an injunction, and submitted that his Honour had power to strike out any unreasonable covenant and enforce the good.

The Judge thought that, on the whole, the agreement was enforceable, and that the plaintiff was entitled to the damages he claimed. Defendant had not made out his counterclaim, and on plaintiff undertaking to hand over a photograph—which defendant claimed, and which was one of the items in it—it would be disallowed.

Judgment was accordingly entered in plaintiff's favour, with costs, leave to appeal being granted, on the application of Mr. Downes.

**A CANVASSER CHARGED.**—At the Liscard Police Court, last week, a respectably-dressed young man, named Leonard Newton Ernest Beaumont, of Albion Road, Walton, was brought up on a charge of obtaining money by false pretences from Mr. May, junior, photographer, of Liverpool. From the evidence it appeared that the prisoner was employed by Mr. May as a canvasser, but on April 6 the business was sold to his father, and the prisoner was discharged. It was alleged, however, that on the 10th ult. he went to a Mrs. Roberts and collected 12s. from her in settlement of an account which was outstanding to Mr. May. Formal evidence of arrest having been given, prisoner was remanded on bail.

**A BISHOPS STORTFORD BANKRUPTCY.**—The Official Receiver for the Hertford district has just issued particulars under the failure of Mr. Tom Bruxby, photographer, Station Road, Bishops Stortford, from which it appears that the debtor has filed a statement of affairs, showing a deficiency of £82 18s. 3d. The report and observations of the Official Receiver are as follows:—The debtor, who has been an adjudged bankrupt, states that he commenced business at Station Road, Bishops Stortford, on July 29, 1905, without capital, and that for two years up to the end of 1904 he was employed as a builder's foreman. About November, 1900, the debtor executed a deed of assignment for the benefit of his creditors. The debtor is unable to state the amount of his liabilities at the time, or what dividend was paid under the deed, but believes that his deficiency was about £2,000. The tenancy of the debtor's residence is stated to be in the name of his wife, who claims the furniture there, as having been purchased by her from the trustee under the deed of assignment mentioned above, and from other persons. At the date of the receiving order one creditor had obtained judgment against the debtor. The unsecured liabilities are in respect of law costs, water-rate, and rent. The debtor states that his present business had never paid its way, but that he had been supported by his wife. The cause of insolvency is stated to be "a libel action brought against me," and the debtor states that he became aware that he had not sufficient property to pay his debts in full on February 9, 1907, when he states judgment was obtained against him for one farthing damages and costs. The only book of account stated to have been kept is a book showing the sales over the counter. No cash book has been kept.

**INDECENT PHOTOS.**—At the Clerkenwell Sessions last week, a Spaniard, named Gil Rovira, was found guilty of having unlawfully sold improper photographs. The prisoner had supplied the photographs (for some of which he had posed) to a newsagent named Scoop, who received four months' imprisonment a little time ago. Mr. Wallace sentenced the prisoner to six months' imprisonment, and ordered him to be deported.

**THE SALE OF A BUSINESS.**—George Thomas Orgill, of Swadlincote, brought an action at the Burton County Court last week to recover the sum of 16s., which he had paid to an agent of Messrs. A. G. Taylor and Co., photographers, of Derby, owing to the non-fulfilment of the order. Mr. A. J. Cash defended. The case for the plaintiff, as stated by himself, was that in the year 1904 he gave an order for the enlargement of a cabinet photograph of his grandmother, and paid the sum of 16s. by weekly instalments. Although two years had elapsed since then, nothing had been done by the defendant to fulfil the contract, and as he had the work done elsewhere he claimed the amount he had paid. Henry James Blount, of the Derby Photographic Company, stated that the business of Messrs. Taylor had been purchased by them, and every effort was being made to fulfil the orders given to the latter. No correspondence relating to the plaintiff's order

could be traced amongst the documents in possession of his (Mr. Blount's) firm, and although Mr. Orgill had been told that many pictures were on the premises awaiting claimants, and that his expenses would be paid if he would go to Derby and see if his was amongst them, he had declined to do anything. His Honour held that the plaintiff was entitled to succeed, as he had given the defendants every opportunity to fulfil their part of the contract and they had failed to do so. Judgment was, therefore, given for the amount claimed, with costs.

**A COUNTERCLAIM.**—Alliance, Ltd., proprietors of the Taber Bas Relief Photographic Co., 115, Newgate Street, sued Mr. James Reeve, 38, Stavard Road, Hanwell, for £22s. 9d. for work done. Defendant said that the plaintiff owed him £3 5s. The Judge said that being so the defendant should have raised a counterclaim. As he had not done that his £3 5s. claim could not be inquired into. He found for the plaintiffs on the claim, adding that the defendant could bring a separate action on his counterclaim.

#### NEW COMPANIES.

**AUSTIN EDWARDS.**—Capital £20,000 (15,000 "A" and 5,000 "B"). To acquire the business of manufacturers of photographic materials, carried on at Warwick and elsewhere, by Austin Edwards, and to adopt two agreements with A. Edwards, and one with A. O. Picot. No initial public issue. Not less than two nor more than four. A. Edwards is managing director. Holders of shares No. 8 to 5,007 and 5,008 to 10,007, respectively, have certain powers of appointing directors. A. Edwards is nominee of first-mentioned group. No qualification. Remuneration (except managing director) not more than £50 each per annum. No manager or servant (except A. Edwards) to be paid more than £500 per annum, except with sanction of general meeting.

## News and Notes.

**NOTICE.**—Owing to "great pressure upon our space a number of articles and replies to correspondents, together with the discussion upon Messrs. Beck's paper on the "Isostigmat" lens, are unavoidably held over until next week.

**THE OIL PROCESS.**—Messrs. John J. Griffin and Sons, Limited, have on view at their exhibition-room in Kingsway a series of four portrait heads by Herr R. Dührkoop printed by the oil process. Our readers who are interested in this process may be pleased to have the opportunity of seeing the results produced by such an artist.

**THE YORKSHIRE UNION.**—On April 20 the Yorkshire Photographic Union held their annual meeting, by invitation of the Sheffield Photographic Society, in the Cambridge Hall, Sheffield. There were about 80 members present representing societies and photographers from all parts of the county. The president of the Sheffield Society (Mr. T. W. Charlesworth) welcomed the members of the Yorkshire Union, and acknowledged the benefits received from the union, both by the Sheffield Society and by himself personally. The president of the union, Mr. Atkinson, thanked the Sheffield Society for their cordiality and hospitality. This, he said, was his second year as president, and he felt that each year it became, and would become, more difficult to faithfully fulfil the duties of president, owing to the popularity of the union. He felt that the photography of the present day was doing a great deal in helping people to see beauty in nature, and to take an interest in historical buildings and objects which would otherwise be neglected. This he regarded as of great educational value, and he urged those present to make the most of the materials close at hand, referring to Hogarth and Constable as examples for their encouragement. The treasurer's report showed that the past year had been successful from a financial standpoint, and the union closed its books with a balance of over £21 to the good, an improvement of, roughly, £2 15s. on the year's working. The general secretary, in submitting his report, first traced the history of the union, its objects and its responsibilities, and then urged the responsibilities of the societies to the union to enable it to carry on its work efficiently. He complained that some societies had appointed delegates who never attended

the meetings, and strongly urged the necessity for those societies taking a more real interest in the work if they wished to have the benefits provided by the union. A hearty vote of thanks to the officers of the union for their work during the year, and to the Sheffield Society for their hospitality, concluded the proceedings. In the evening there was an entertainment provided, in addition to an exhibition of pictures from the various Yorkshire societies, and lantern slides by members of the Sheffield Society.

**STOLEN LENSES.**—We are informed by the firm of Carl Zeiss that a robbery has been committed on their premises at 29, Margaret Street, and optical instruments to the value of over £500 stolen from the premises. At Messrs. Zeiss' request we publish a list of the stolen articles which will, we hope, prevent a number of them from being accepted for purchase:—

Achromat objective 3 mm. 1.30 No. 415, apochromat objective 3 mm. 0.9 No. 888, apochromat objective 2.5 mm. 1.25 No. 525, apochromat objective 8 mm. 0.65 No. 2,428, apochromat objective 16 mm. 0.50 No. 5,064, compensating ocular 2, folding aplanats X6, folding aplanat X10, folding aplanat X10 and X20, folding aplanat X20 and 27, folding aplanat X16 and 27, large Brucke lens, improved alcazar in sleeve, folding aplanat in ivory handle, dissecting lens 1,404.

Micrometer eyepiece with drum, index ocular 195, projection ocular 2, apertometers 155 and 156, projection eyepiece 2, small mechanical stage 1,574, mechanical stage (new model) 1,565, large mechanical stage 3,553, polariser and analyser 170, selenite films, centring achromatic condenser.

Screw micrometer ocular 528, astro objective No. 221, sporting telemeter No. 120, stereo Palms 9 x 12 cm. No. 3,833, two Tessar lenses Nos. 80,861-65, one single Tessar 145 mm. 81,901, one front-board, one Hilton adapter 9 x 12 cm., two slides for above.

One cut film holder 9 x 12 cm., minimum Palms 9 x 12 cm. No. 4,813, Unar lens No. 63,821, tele-tube No. 806 with negative 77,588, minimum Palms 4 x 5 in. No. 4,259, Tessar lens No. 66,534, film pack adapter 4-plate, roll-holder 4 x 5 in. No. 2,918, telephoto lens No. 81,802a, minimum Palms 2 x 3½ in. No. 5,753, Tessar 4.5 88,802, tele-adapter and negative lens 1,211, universal Palms 9 x 12 cm. 5,929, double protar in compound shutter 81,476-85,575, wide-angle lens 80 mm. 77,925.

Heyl's actinometer, Zeiss pack adapter 11,796, stereo Palms 9 x 18 cm. 3,270, two Tessars 68,659-547, three double dark slides 9 x 18 cm.

Binoculars X4 de luxe 3,535, X6 de luxe 11,351, X8 de luxe 49,090, X4 3,539, X8 48,486, X10 10,780, X12 11,762, X5 11,229, X7½ 10,565, X5 and 10 859.

Monoculars X4 144, X6 291, X8 1,896, X7½ 1,298, X10 1,098, X12 1,444.

Zigmond's coloured glasses (one set), two demonstration prisms, hand spectroscope 203-204, Adix calculator, Unicam shutter 99,530, Goerz spectro shutter 3,310, Linhof shutters 4,355, 4916, Goerz shutter 4,659, focussing glass x6.

Protar lenses 86 mm. 71,194 rotating diaph., 350 mm., 71,123 double Protar 183-183 mm. 76,572-3, 285-224 mm., 73,381-72,059, 285-285 mm. 81,569-70; Tessar lenses 75 mm. 73, 393, 40 mm. 68,215; Planar lenses 110 mm. 74,436, 100 mm. 78,697, 20 mm. 80,681; Tessar lens 155 mm. 73,468 in compound shutter.

Teletube III. No. 585 with negative lens 45 mm. 79,754; positive lens 135 mm. 52,873; Tessar lenses 210 mm. 81,135, 155 mm. 77,694, 112 mm. 64,949; Planar lenses 50 mm. 38,186 and sleeve, 76 mm. 35,446 and sleeve, 100 mm. 39,056 and sleeve, 205 mm. 38,695 and sleeve; projection aplanat 250 mm. 1,005, aplanat magnifier X6, one hand spectroscope 204, one projection aplanatic lens 183 mm. 10 us.

**ZIGAS COMPETITION, 1907.**—The enormous number of entries for this competition, which closed on March 31 last, amply testified to its popularity, and the judge, Mr. P. R. Salmon, had no easy task in awarding the prizes. The following are the successful competitors:—"Open" classes: Section A—1st prize, £5, J. Ayton Symington, Kew; 2nd, £3, A. H. Robinson, Scarborough; 3rd, £2, Robert Low, Cork. Prizes of 5s. were also awarded to F. W. Beken, Cowes; James Dunlop, Motherwell; E. R. Bull, Forest Hill; J. Anderson, Belfast; J. F. Johnson, Harlesden; C. R. Dodd, Clapham; Harry Cross, St. Leonards; James Omond, Orkney. Section B—1st prize, £5, Herbert A. Gane, Bayswater; 2nd, £3,

Holding, Wimbledon; 3rd, £2, Miss Frances Pitt, Bridge; and prizes of 5s. each to Miss J. Hamilton, Hammersmith; I. Poole, St. Helens; Harry Holt, West Kirkby. "Novice" class: Section A—1st prize, £5 10s., J. W. Carr, Manchester; £2, S. Featherstone, Rolls Road, S.E.; 3rd, £1 10s., John Leeds; and prizes of 5s. each to W. Ingram, Glasgow; E. Till, infield; F. G. Price, Aberberg. Section B—1st prize, with 2nd, £2, F. Mears, Gnosall, Staffs; 3rd, £1 10s., T. Rivers, and prizes of 5s. each to Miss J. M. Bryden, Bideford; F. Price, Aberberg; T. Lambert, Brighton. The "Zigas" competition for professional photographers only closes on June 30.

THE CINEMATOGRAF in Science, Education, and Matters of "is the title of a booklet by Mr. Charles Urban, whose object prove that the time has now come when the cinematograph should be recognised as a national instrument by all those responsible for the advancement of education, science, and state affairs in general. Mr. Urban endeavours to show that the equipment of the school, scientific laboratory, school, technical institute, etc., is incomplete without its moving picture apparatus, and his arguments are well worth the consideration of those to whom, from its the booklet would appeal. Copies will be forwarded gratis on application to the Charles Urban Trading Company, Limited, 48, Abchurch Lane, Street, Shaftesbury Avenue, London, W.

PARTNERSHIP ACTION.—On Monday last, at the Watford County Court, an action was heard in which W. F. Cooper, of the Cooper Laboratory, sought an injunction to restrain J. H. P. from disclosing the secret of manufacture of a direct sepia dye paper, which the plaintiff stated had been discovered in the laboratory, and whilst the defendant was in his employ. The judge, in declining to grant an injunction, stated that he had come to the conclusion that the defendant was not a servant of the plaintiff, and that they were, to all extent and purposes, in partnership in the manufacture of the secret, and both were therefore entitled to it jointly. The judge declined to grant the defendant his costs, as he considered that the defendant had taken up a perfectly unjustifiable attitude, and he was not satisfied that the defendant had possessed, as he stated, a secret, on the assumption the arrangement had been concluded, nor did he think that the defendant had acted quite honourably.

RAILWAY PHOTOGRAPHY.—The death of George Edwards, a news- and photographer, of Queen's Road, Peckham, who was knocked by a train on the Chatham and South-Eastern Railway, near Uxley Station, formed the subject of inquiry at the City Coroner's Court on Monday last. Edwards was in the habit of photographing of workmen, and railway officials stated that his object in being on the railway was to solicit business from the men. The foreman of the bridge repairs said the deceased had no right to be on the railway at all, and the company's engineer agreed that Edwards was trespassing when he met his death. The Coroner said the fault lay with Edwards, but he wanted to know if it was possible for the company to prevent such an accident recurring. Mr. Groves, appeared for the company, said a strongly worded notice could be issued among the members of the staff, calling upon them to warn any unauthorised photographer who appeared on the railway. The jury, in returning a verdict of "Accidental death while trespassing," expressed the opinion that the company should take more stringent measures to prevent trespassing on the railway.

LATE MR. DESMOND.—We regret to record the death of Mr. Desmond, of Priory House, Cardigan. The deceased gentleman had conducted a photographic business in several Welsh towns.

"OPTICAL LANTERN AND CINEMATOGRAF JOURNAL," formerly "Optical Magic Lantern Journal and Photographic Enlarger," will be issued weekly instead of monthly, and will be entitled in the future "The Kinematograph and Lantern Weekly." It will be issued on a trade only, under the editorship of Mr. Theodore Brown, by Messrs. E. T. Heron and Co., 9 and 11, Tottenham Street, Tottenham Court Road.

EASTERN PHOTOGRAPHIC SOCIETY.—The following is a list of the members and committee for the year 1907-1908: President—Dr. A. S. G. Vice-presidents—C. D. Baxandall and R. W. Wearing. Secretary—A. Davies, W. A. Tester, S. D. Stevens, J. H. Parker, and A. J. Braithwaite. Hon. secretary—John Holt. Hon. treasurer—W. Gunson. Hon. auditors—A. R. D. MacDonald and J. H. Arkle. Librarian—W. Arkle.

## Correspondence.

### THE VARIATION OF THE TIME OF DEVELOPMENT WITH THE TEMPERATURE.

To the Editors.

Gentlemen,—I only received the "B.J." for April 19 at the moment when I was leaving Arosa, and as my note-books, etc., were packed up, I could not at once reply to the interesting letter of Mr. Cranston.

As to M. Houdaille's statement, it is certainly correct in principle, but the method of applying it suggested by M. Clerc is erroneous. As your correspondent, "G. S.," points out, the increase of 5 per cent. should be calculated from degree to degree, which Mr. Cranston in his letter to you has correctly done by my method given in the "Photo. Journal" for May, 1906.

The temperature coefficient is not precisely the same for every developer, as Mees and Sheppard have pointed out, and therefore the 5 per cent. rule can not be applied to every case.

I have not by me in Zurich "Real Orthochromatism," but, taking the data from Mr. Cranston's letter, we have—

Time at 50 deg. F. (10 deg. C.) = 7 minutes.

Time at 65 deg. F. (18.8 deg. C.) = 5.25 minutes.

From these data we find the log of the temperature coefficient for 1 deg. C. for the developer used by subtracting the log of the smaller time from the log of the greater time, and dividing the result by the difference in temperature—

$$\log 7 - \log 5.25$$

$$8.3$$

$$\log 7 = 0.8451$$

$$\log 5.25 = 0.7202$$

$$.1249 \div 8.3 = 0.0151$$

Then the requisite time of development at 15.5 deg. C. will be found by subtracting from the log of the greater time the product of the log of the temperature coefficient, and the difference in temperature between 10 deg. C. and 15.5 C. The result is the log of required time—

$$\log 7 - 5.5 \times 0.0151 = \log \text{ of required time.}$$

$$\log 7 = 0.8451$$

$$0.0830$$

$$0.7621 = \log \text{ of } 5.78 \text{ minutes.}$$

which figure substantially agrees with the 5.75 minutes given in the pamphlet.

I do not quite understand how Mr. Cranston gets the 4½ minutes mentioned in the last paragraph but one of his letter, but perhaps he has not first calculated out the correct temperature coefficient for the developer used.—Yours faithfully,

Pension Neptun, Zurich, Suisse.

To the Editors.

Gentlemen,—As the effect of temperature varies very considerably with different developers, the arithmetical rule proposed by Col. Houdaille can certainly not hold good for all. As a measure of the effect, in the quantitative study of development, I have used the so-called "temperature-coefficient for 10 deg.," this being the ratio of the velocities of development at 20 deg. C. and 10 deg. C. respectively. From a paper of my own (Trans. Chem. Soc., 1906, 89, 530), and one with Dr. Mees (Roy. Soc. Proc., A., 1905, 76, 217), the following data are taken, which exhibit this variation—

Developer.	Quinol.	Ferrous Oxalate.	Hydroxyl-amine.	Rodinal.	Metol.
T.C.	2.8	1.7	2.00	1.5	1.3

This means, of course, that hydroquinone at 20 deg. C., develops 2.8 times as fast as at 10 deg. C., and so on. For calculating purposes, however, it is necessary to know the change for any variation of temperature within a certain range, and for this an empirical formula, deduced from a series of measurements, is valuable. That

given by Mr. W. B. Ferguson, K.C., in the "Phot. Journ." for May, 1906, answers very well over a short range, only different exponents must be used with different developers. The choice of a formula is chiefly a matter of convenience and the range over which it is to be used. I found that for ferrous oxalate from 0 deg. to 30 deg., the formula  $\log K = -1806/T + 7.60$ , where K is the velocity of development and T the absolute temperature (temp. Centigrade + 270 deg.), represented the results very well, but generally the form

$$\frac{t}{t_0} = \left(\frac{T_0}{T}\right)^c \text{ where } t, t_0 \text{ are the times of development corresponding}$$

to the required temperature and the initial temperature, whilst C is a constant, which must be calculated from experimental results, yields sufficient accuracy for practical purposes.—Yours, etc.,

Marburg, a/L., Germany.

S. E. SHEPPARD.

#### UNIFORMITY IN HALF-TONE NEGATIVES.

To the Editors.

Gentlemen,—I have not read Mr. Biermann's article in the "Penrose Annual" for 1907, so I do not know what similarity it may bear to the method I was advocating at the R.P.S. When it was suggested at the meeting the method was not new I thought the charge of plagiarism was against myself. I gave the date of my first publication in the "B. J." for March 13, 1896, as evidence that I could not have copied from "Penrose" of 1907. I commented on the significance of the fact of us being fellow-townsmen, and remarked that if the methods were identical, I thought it must have been derived more or less directly from myself. The fact that I claim ten or eleven years' priority of publication will clear me, I hope, and if identical methods occur twice independently in the same town it is very interesting.—Yours truly,

84, Stanmore Road, Birmingham.

E. C. MIDDLETON.

#### A NEW METHOD OF MEASURING THE TIMES OF PHOTOGRAPHIC SHUTTERS.

To the Editors.

Gentlemen,—In reply to Mr. Hunter's letter, in your issue of the 19th inst., and Dr. Glazebrook's, in your issue of the 26th inst., in which both writers express their regret that my name was not mentioned in the paper referred to in my previous letter in your issue of the 19th inst., I willingly accept these apologies.

At the same time, both writers use the argument that Mr. Hunter's method is different from my own, a statement which I cannot accept, as from the first I have actually used a scale on the slit of my apparatus for measuring the low speeds (or, as described in my specification, "estimated"), and, if Mr. Hunter only gets within 20 per cent., perhaps it would be more in keeping were he to use this word.

Mr. Hunter mentions in his letter that I do not describe my method of photographing in my patent. As I make no claim for this it is not necessary for me to explain. I enclose, however, a print for your inspection, showing that I can get confirmation of my method by photography. This is obtained simply by using an ordinary camera in front of the slit, and a powerful illuminant substituted for the one used for visual testing.

Another point raised by Dr. Glazebrook in his letter as to the similarity of the two methods, which in a way raises the question as to whether my method is a new one, and, following this, a subject for a patent. Fizeau certainly used a disc with slots—to be accurate, a toothed wheel—but this was for a different purpose, and used in a different manner. I do not claim in my patent simply the disc with radial slits, but a particular combination of parts and for a particular purpose.

The similarity of Mr. Hunter's method and my own does not rest only on our both using a disc with radial slits, but Mr. Hunter uses the whole combination, as described in my specification *i.e.*, an illuminated stationary slit, in combination with a revolving disc, with a number of radial slits as, and for the purpose of, measuring the speeds of photographic shutters.

As proof of this, in his paper he says. As an alternative method persistence of vision may be used (which he now acknowledges as being the method used by me), and, unless he uses my apparatus, I fail to see how these results are possible.

However, this is a question with which I need not trouble you, for if the National Physical Laboratory continues using the apparatus

without my permission, my remedy will be in another direction, not through the Press.

A. KERSHAW,

Photographic Apparatus Manufacture

St. Columba Street, Woodhouse Lane, Leeds.

April 27, 1907.

[The following are the two diagrams referred to by Mr. Kershaw with his description of them.—Eds. "B.J."]

Period.

Period.

Roller Blind Shutter: No. 1, 2, and 3, period = 1.22 sec., speed 1-25; No. 4, period = 1.24, shutter speed 1-25. Those

print are with a focal-plane shutter, with varying periods. The sharp definition which enables accurate readings to be Nos. 6 and 7: These two are almost identical, and are about sec. The period is 1-100 sec. Nos. 12 and 13: Period - c., speed 1-57 sec.

# N EXTEMPOREISED FOLDING TILTING TABLE.

To the Editors.  
Gentlemen,—I enclose photograph of a simple contrivance for photographs from any window. A B. is a flat piece of wood;

foot like the foot of a stool. This rests on the window sill. is an upright piece attached to A. B. with a thumb screw. camera can thus be tilted at any angle.—Yours, etc.,  
n Street, Strabane.

R. GALLAGHER.

# BLISTERS ON BROMIDE.

To the Editors.  
Gentlemen,—In reference to the correspondence on the subject of blisters on bromide paper, I have read with interest what little attention has been given, and regret the scarcity of contributors. My experience the trouble seems to have a "selective" peculiarity applied to the users of bromide paper. One hears of those who never free from the infection, while others experience an immunity in all circumstances. Personally, over a period of some eighteen months of bromide paper work, I have been fortunate to escape any trouble from blisters, but on the occasions when I was troubled, nothing I could do in the way of treatment of the paper was of any use. Equalisation of temperatures, formalin, alum, etc., completely even to minimise the defect.

On the other hand, although I have had so little personal experience I have had a large experience of other people's sorrows on the

one exception, that of an Edinburgh firm, who suffered from a change in the water supply to one of a colder temperature. My single recommendation has been to "change the paper," without exception the remedy has been effective.

Too vigorous chemical treatment nothing is easier than the treatment of blisters, but by the ordinary treatment for which the paper is made I do not think blisters should occur.

I entirely agree with Mr. J. Pike that the paper is at fault; and the manufacturer who sends out inferior stuff in that direction should be made to suffer in the only possible way.

Those who have had a wide experience of different manufacturers know that a blisterless (under ordinary conditions) paper can be made, and remain constantly reliable; on the other hand, if some one likes to depart from manufacturer's instructions and subject paper to extraordinary conditions, they are justly served when it comes.

It always seems a pity to me that such a beautiful and comprehensive printing process should ever suffer from unjust criticism, whether it be due to the manufacturer or the user.

It is, however, one undoubted cause of blisters entirely outside the manufacturer's control, and not always in control of the consumer. In firms where time is money: I refer to the difference in the nature of developer and fixer, and washing water.

In the case of the firm above mentioned, my recommendation to transfer straight from developer to acid fixer, and the use of a hypo eliminator to reduce the time of washing, has proved effective.  
—Yours, etc.,  
C. WINTHROP SOMERVILLE.

"Lyrrath," 117, Hazelbark Road, Hither Green, S.E.

April 26, 1907.

# Answers to Correspondents.

\* \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\* \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

## PHOTOGRAPHS REGISTERED:—

Brimmell Bros., Church Street, Launceston. Combination Photograph of Views of Launceston with the Arms.

A. Hubbard, 7, Exchange Walk, Nottingham. Five Photographs of Miss Pansey Montague.

W. McQueen, 7, Oldham Road, Royton, Lancashire. Photograph of Railway Smash at Cowhill, Oldham.

## DRAWINGS REGISTERED:—

H. P. Simms, 12, High Street, Chipping Norton. Two Pen and Ink Drawings: Man Climbing Lamp-post to Light Electric Light with Matches. Market Square, Chipping Norton, Describing Local Joke.

STUDIO AND LENS QUERY.—1. I am having a studio built, size 26ft. x 12ft., and wish to know what length of focus of lens would be most suitable? Could I obtain fairly or passable results with one of the cheap portrait lenses, as my purse is rather limited, and can hardly afford a first-class portrait lens? Is speed of the best make of lenses the only advantage over cheaper kind. I have noticed that cabinet portrait lenses are advertised as low as £2. Do you think one of this description would be good enough to start with? 2. The glazed side of the studio will face N.E. What colour blinds would you recommend for top light and side light? 3. Would French, grey, or pale-blue paint be suitable for interior of studio woodwork? 4. I wish to cover the plain glass over with a substance, to keep people from looking through. What would you recommend? Something that will not obstruct out too much light, and, if best, inside of glass or the outside.—STUDIO.

1. The most suitable lens for this length of studio, if you have only one, would be from 11in. to 12in. focus. Large aperture is not the only advantage in an expensive lens, which has many other qualities over the cheaper kinds. Of course, you must not expect much for the exceedingly low price you quote, considering that the cost of a high-class instrument for cabinet portraits is something like eight times that quoted. 2. Pale green or dark blue would be a good colour for that aspect. 3. Either colour would be suitable; the first-named would perhaps be the better. 4. If the side of the studio were glazed with fluted glass, people could not see through, and no light would be obstructed. The glass may be obscured by stippling it over, on the inside, with starch paste, in which a little whiting has been mixed; or it may have tissue, or tracing paper, or linen, attached to the sash bars with paste, or you can use the plain "window decoration," or Reinemann and Co., New Zealand Avenue, Barbican, E.C.

FAULTY LIGHTING.—We enclose you a rough untouched print, and wish to ask your advice about same. 1. You will notice that there is no light and shade in the hair, and the face and neck are much too dark. We have always used "plain lighting," but to keep up with the times we find that we must introduce fancy

lightings, but you will see our results have not been very successful. A lot can be done to the negative by working on it, but we wish to get the light so that there will not be much of that needed. We shall be pleased if you can kindly advise us in what way we can improve on same.—FORWARD.

1. The lighting of the portrait sent is very faulty, as you say, but we do not see how we can help you, as you give no idea of the form of your studio or the arrangement of the blinds when the picture was made. What is required is more reflected light on the shaded side of the face to soften the shadows—that you can surely easily arrange without assistance. 2. As we have no idea whatever what the system is, we can offer no opinion on its merits. Possibly it may be of assistance to you, as you seem to be somewhat at sea at present.

STUDIO QUERY.—I am building a studio, and I should be glad of your kind advice. I enclose rough sketch and plan. Do you think the area of glass is enough? The studio light faces north, and it will be glazed with 21oz. clear glass; the whole area of glass about 84 square feet; area of studio, 10ft. x 22ft. 1. Is the area of glass enough and distributed rightly? 2. What curtains would you advise, and how to be hung? 3. Where could I get the "Plastine" recommended by a correspondent in a recent issue for glazing?—W. J. R.

1. Judging from the sketches we would suggest that you should have eight feet of glass at the side and roof instead of six; also that the height to the ridge be increased a foot or so. 2. For the top blinds, pale green or medium blue holland, on spring rollers, would be good, and for side curtains art serge of similar colour would be very suitable. 3. We do not know the material. If you will give us the reference to it we will look it up.

W. D.—We should advise carbon, platinum or bromide (in this order) if the prints are to be made in England and sent out, but for working on the spot by those not experts, we should recommend bromide.

J. T.—A 10-inch is better than the shorter focus, on account of the better perspective. We should certainly decide in favour of No. III., as you will need a greater covering power, and the aperture is quite large enough.

M. D.—We should say the price you name a reasonable one for the two negatives. For a similar distance one guinea for one whole-plate negative and print would be an average charge for good work.

GASLIGHT EMULSION.—Will you please give me a formula for gaslight emulsion for postcards, rapid and slow, as I want to sensitise them myself?—J. HARRIS.

No formula for gaslight emulsions has, so far as we are aware, been published, and makers' formulæ are naturally guarded very carefully. It is stated, however, to be a chloro-bromide, and the following is an excellent formula for this:—

Ammonium bromide .....	65 grains.
Ammonium chloride .....	216 grains.
Nitric acid .....	90 minims.
Gelatine .....	24 ozs.
Water to .....	20 ozs.

Allow the gelatine to soak for an hour and melt by the aid of a water bath, add the salts and acids, and heat to 140 degrees Fahr., and add slowly with constant stirring

Silver nitrate .....	720 grains.
Water to .....	20 ozs.

As soon as mixed, pour out to set, and wash. Then re-melt and add some gelatine, previously well washed in water, the quantity varying according to requirements. It does not pay to do this work unless the operator has some experience in emulsion making and a coating machine and drying conveniences.

JUSTICE.—We think he is fully entitled to use the words in question. He must not use the Royal Arms. We reply to your query as to canvassers under "Ex Cathedra."

F. SIMOND.—"Photo-Revue," 112, Rue d'Assas, Paris.

ETCHING GLASS.—Would you kindly inform me how to proceed to make a focussing screen by etching with fluoric acid or otherwise?—IRIS.

It is not very easy to get a fine matt with hydrofluoric acid. The usual way is to grind two glasses together with the finest emery powder. We advise you to try the process on page 713 of the "B.J. Almanac," 1907.

VALUE OF LENS.—Some time ago I bought a 1-1 plate lens with following (as near as I can make out) on: "Vallantin, (something here I cannot read), M. Leberours, Paris." I should be extremely obliged if you would give me some idea as to its value.—X. Y. Z.

As you cannot decipher the engraving on the mount of the lens it is evidently a very old one, and of ancient construction. We should say it has very little commercial value at the present time. It may be a very serviceable instrument, but that will be able to see for yourself by taking one or two pictures with it. Some of these old French lenses are fairly good, but not up to those of modern construction.

OPERATOR.—There is none.

OTHELLO.—Such repairs are done for the trade by small shops, but do not work except for them. We advise you to send the lens to the firm supplying it.

TYRO.—1. (a) Any ortho plate with either the screen made by makers or a filter yellow K filter; (b) naturally a panchromatic plate with deeper filter must be used. 2. Unless you have special drying facilities and can work in the dark, we should advise you to undertake this. 3. It is not corrected for red, and will not correct for red. 4. Yes, and is suitable for all-round work, but not for stand development.

W. H. C.—Imogen sulphite is a secret preparation. Pyrocat is a large constituent of the other developer, but whether only one we cannot say.

COPYING WITHOUT A CAMERA.—Will you kindly inform me whether it is possible for anyone to copy photographs from others without a camera or lens. A lady friend of mine sent me a photograph from America, which she says she copied without a camera. They are real photographs, and certainly very good, and can hardly tell they are copies. She tells me she used a special light paper, and made a paper negative from the photograph and then printed them in the ordinary way. Will you kindly inform me where to get the paper, or will the ordinary Pyrocat do as well? She says she can do postcards in the same manner. I should like to be able to do some myself. I have got a snapshot camera, but I cannot copy with it, and I have a cabinet photograph from which I should like to copy and make some postcards if it is possible. By giving me any information on the subject you will greatly oblige.—SUBSCRIBER.

Certainly you can print from the unmounted photograph contact on to a gaslight or printing-out paper. The exposure will be a good deal longer than from a negative, and the quality of the paper in each case may be very evident. If the print is mounted, the above method is, of course, impracticable, but it is possible to make copies by the following process, though we cannot call it one suitable for regular work:—Place a sheet of phosphorescent paper (i.e., paper coated with calcium phosphide) in contact with the photograph in artificial light (light). The paper should have been previously exposed to light for a few seconds. After about five or ten minutes remove the phosphorescent paper, which is now very faintly luminous, and place it, in the dark, in contact with bromide paper, keep the two together for about twenty to thirty minutes at a temperature of 120 deg. F., afterwards developing.

\*\* NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

ness and technical expedients, including a follow-up system, dark-room checking methods, and an inexpensive dark-room sink described before the recent Convention of the Professional Photographers' Society of New York in competition for a 50-dollar (P. 344.)

tain Owen Wheeler strongly recommends a long hood for the lens as a means of securing brilliant negatives. We receive a series of telephotographs taken by Captain Wheeler the aid of the hood. (Pp. 342 and 343.)

interesting lawsuit connected with a process for direct sepia prints appears under "Commercial and Legal Intelligence."

"Isotigmar" lens. The views of others on Messrs. Beck's paper are given on page 347.

Royal Academy contains many examples of modern portraiture which may be studied by any professional photographer desirous of advancing his own work. (P. 342.)

contents of the week include a folding stereoscope and two new lenses. (P. 351.)

de-light on the postcard business is cast by a recent case. (P. 346.)

recent paper by Dr. E. Demole on the latent image contains conclusions which appear to call for criticism. (P. 346.)

take exception to some pronouncements on orthochromatism made by E. A. Salt before the Croydon Camera Club. (P. 350.)

ing society proceedings have been Mr. H. Stuart on "Gummate" at the L. and P., and Mr. J. Watson on "The Tannin" at the R.P.S. (P. 355.)

## EX CATHEDRA.

### Rights In Research.

The report of the case of Cooper v. Gillard, which we publish on another page, should make interesting reading for any persons who are collaborating in the investigation of processes with a view to their commercial application. Through lack of an express undertaking in writing that, in the event of a process of a direct sepia bromide paper proving successful, neither was to dispose of it without the sanction of the other, the Judge could not grant the injunction asked for, but his summing up strongly emphasises his view of the moral obligations of the plaintiff, who, nevertheless, from his share in the researches, was not regarded by his Honour as an employee, and, therefore, the rights of each party to the discovery were those of partners. The case should serve as a reminder of the need of a business-like agreement in such cases.

\* \* \*

### A Wave of Orthochromatism.

According to a report published on another page, orthochromatism is what a particular club and the photographic world generally is suffering from, with the result that our negatives want "sparkle, life, and go," and our pictures are consequently flattened, wanting in gradation and the subtle play of light. We have here an expression of opinion which is still far too commonly met with, notwithstanding the fact that for over twenty-one years, year in year out, some one or other has been preaching and proving the advantages of the colour-sensitive plate. The truth of the matter is that the adherents to this opinion cling tenaciously to old thoughts and practice, and are loth so to change their procedure as to take advantage of the greater powers at their command. The familiar is preferred to the unfamiliar, no matter how much more truthful the latter may be. Their comparative tests, if they make them, are too often made with their thumb in the scale-pan, like that of the itinerant fruit vendor. Their criticism of the results is based, as all criticism must be, on their past experience and knowledge, and

"Truth new-born  
Looks a mis-shapen and untimely growth."

\* \* \*

### Sparkle.

Exactly what is this particular virtue, which a negative must possess, we have never been able to learn. True, it is defined as "life," "go," "pluck," but a rational explanation it is impossible to obtain. It is, according to these authorities, that particular characteristic which a wet-plate negative possesses, and if you do not happen to be an old wet-plate worker, as they are, then you are about as wise as before. If you obtain a wet-plate negative and examine it, you are not much wiser, and a print from the same merely shows you black masses where there should be the tender play of light

and shade in the various greens, and you involuntarily wonder if the grass and trees are actually as black as the proverbial coal-hole. For so long have these workers relied upon the wrong values given by ordinary plates for obtaining pictorial results, that they are utterly incapable of making pictures with the new colours. Their palette is as restricted as that of the black-and-white line artist, and given a complete colour-box they are helpless, and make a hopeless, infantile caricature. Then they blame the tools.

\* \* \*

#### A Reserve Power.

Colour-sensitiveness, orthochromatism, or any other term that one may apply to it, is merely a reserve power, which may or may not be used at the will of the operator. That one does not want to use it is no reason why one should not have it. It would be interesting to know, putting the matter in its baldest form, whether the lecturer who is responsible for these views, would prefer to go away for a holiday with an extra five pound note in his pocket, or with merely enough money for his bare necessities. It does not necessarily follow that because one has the reserve force that one need be extravagant. One of the arguments in favour of the adoption of ordinary plates is, we think, most unhappy—for the said lecturer's views. He tells us that many leading flower photographers use ordinary plates from choice, not from innate conservatism, and then adds: "Their choice is probably deliberate, assisted by the fact that they can mostly avoid heavy colour contrasts." Quite so; their work is necessarily restricted, which is probably about one of the strongest arguments in favour of the orthochromatic plate.

\* \* \*

#### The Question of Gradation.

Let us tackle our friend, however, on his question of gradation. According to him, by the use of colour-sensitive plates we "lose much of the infinite gradation and subtle play of light." Is this a fact, or is it merely an erroneous preconceived prejudice? This can be only answered by direct photometric measurements, and, as proved by both Drs. Eder and E. Stenger ("B.J. Alm." 1907, p. 836), the gradation under a set of three-colour filters is approximately the same for the same plate, therefore one may argue that under a yellow filter the same fact will be apparent. It is obvious, then, that, given correct exposure and correct development, the colour-sensitive plate is in this respect *pari passu* with the ordinary. As to the greater difficulties of working orthochromatic plates, these are not dependent on the plate but on the operator. Some people cannot use a tack hammer, let alone a scientific production like a photographic plate or printing paper, and many are deterred even from using such simple processes as carbon and platinum printing because these are not of the printing-out order. One always has a lurking idea that the lecturer in question may be speaking with his tongue in his cheek; his views are not always orthodox, and he is the first to parry this term by the old definition of "his doxy and the other man's doxy" with a quiet twinkle that makes strangers wonder what he does mean or believe.

\* \* \*

#### Telephoto Fog.

Negatives taken with the telephoto lens so often suffer to a greater or less extent from veil that it is usual to hear a telephoto print of average clearness specially commended on this account. Yet, except for the caution that the positive lens of a telephoto combination should be shielded from direct rays of the sun, we do not recollect to have seen the screening of the lens particularly emphasised as a means of avoiding flatness. The great benefit of thus screening the lens with a hood, fully large enough to cut out ex-

traneous light which falls upon the surface even comparatively small angle, was recently demonstrated, by Captain Owen Wheeler, by a number of comparative prints taken with and without a lens-shade, which, in particular case of Captain Wheeler, takes the form of a conical hood extending in some cases as much as 18 inches from the lens mount. In the "Pall Mall Gazette" for May 2, Captain Wheeler, in the course of an address on service telephotography, speaks of the great satisfaction which he has derived in his own work from regular use of a hood, particularly when employing fairly high magnifications as twelve and fourteen times. He has arrived at the lens hood as the most effective means of excluding extraneous light after putting other expedients, such as internal diaphragms, to the test. Its practical use during a number of years past, and its importance, therefore, attaches to his preference for it, and to the fact that Messrs. R. and J. Beck have now put it on the market in a convenient form.

#### PORTRAITURE AT THE ROYAL ACADEMY.

To write about pictures for a photographic journal is usually not an inspiring task. The critic has a feeling that he should always have the photographic point of view in mind, and this consciousness is as a millstone tied round the neck. So many matters have to be disregarded, especially those that comprise execution and colour. What remains amounts to little more than the design and tone of the works. It ought to be nearly time, however, to admit remarks on colour, since photographers have happily at last invaded that hitherto forbidden land, if it be granted to the critic that he may introduce a camera man, as such, to the painter's paradise, the reviewing of pictures will be a less heart-breaking task.

In a paragraph last week mention was made of the works of Sargent, and since no other portrait painter earns so much of both praise and abuse from the critic that stand and gaze, he may very well furnish the remarks of this review. As to the "Lady Sassoon," all artists will agree that it is one of those high-water marks recording the flow of art throughout the centuries. I do not too much to say, we believe, that in years to come "Lady Sassoon" will be spoken of, written of, bought and sold, or will become an ornament to some national gallery thus gaining an equal footing with "The Duchess of Devonshire and Child," "Lady Hamilton," "Mrs. Siddons," works of similar eminence. For, in spite of all that has been said as to Sargent's failings upon the psychological side, he shows himself here to have captured not only the elusive touch that makes a portrait breathe, but that which gives it the convincing impression of movement of the facial muscles. Lady Sassoon gracefully holds her black silk skirt as she passes before us—the swish of her silk as she turns—and as she moves she throws us a look of irresistible greeting. Her eyes beam recognition; her lips prepare to utter, not the conventional accosting of a crowded reception, but the friendly word. It has been thought that the work is full of accents. Is it not, however, all the greater for avoiding the centralising trick of moderns, who realise a face amidst a wilderness of suggestion, wherein the eye cannot rest if it would? Its mere execution is magnificent. Ladies may be overheard reviling the "awful" hands. Of course, these fair critics do not understand the difference between the claims of a modern work and a Holbein. All who look at this work from the distance of the settler's opposition will be delighted. Painters alone may go nearer to profit. The wizard Academician has four other portraits here; but having spoken of No. 237, it were beyond

cession to speak of the rest, for comparison dwarfs line as most of them are.

The same room are four other portraits, which of lives mark out 1907 as a year of good portraits. Henry Van der Bergh" is a vivacious one by S. J. n, R.A., of a large and easy style and fine colour. Solid and genuine in effort, and admits a somewhat view than the last, wherein it will commend itself more to those who see "by the nose."

Next noteworthy work is a group by Geo. W. rt. It is certainly the most individual work of d in the show, and possesses a touch of that ness without which younger men seem unable to mark. Two ladies dressed in the present fashion together in the open air, one with her arm over oulder of the other. By their side is a boy, who have stepped out of a Flemish picture, or have been by Dürer. He has bare legs and sandals, and s to be wearing his father's coat, which, thrown displays the half-vest half-stays garment worn by children. His air of swagger suggests the son ip IV., by Velasquez. In the nearer foreground is ing baby, just placed upon the ground by his , and having his clothes all bunched up, so as w his chubby thighs. It is all intensely natural, t strangely unnatural, even to the tree stump with arishing sprout upon it. Evidently it is a bid for by a man of great power. Its worst parts are the hich sticks to the figures and is, after all, but a ound, and the largeness of the taller lady's hand.

Shannon, A.R.A., scores with his "Mrs. Henry J. imer," which, though a little unpleasantly dark, is al in pose, in design, and in expression. The subd Mr. Shannon's treatment of it has resulted in a ting and haunting portrait.

Other work of the "new" men in this room which attention is Mr. Young Hunter's portrait of his ho appears at full length in a gown of gorgeous and emerald green. Strong and admirable as it cannot but detect the "academy pitch" motive aces it so far from the spirit of restraint and y of the great Sargent near which it hangs.

Gallery VIII. is the group of nine life-size figures H. F. Bacon, A.R.A. Its disjointed title, "The Butterfly (The Harvey Family)," very neatly sums complex motive; for it totters between a family por-ou and a subject picture. Mr. Bacon has failed to he butterfly interest either his models or the spec- In a garden scene, a bored family are sullenly for the tea to draw of which the eldest daughter arge. Of course, the difficulty of blending nine s, all equally made out, into a homogeneous whole ns of a pictorial motive is almost insurmountable. two great Dutchmen have done it; but Mr. Bacon . Taken separately, his figures are unexceptionable.

ge Henry, the new Associate, sends four works, the hich are perhaps the two that adorn Galleries d X. The first is a charming design called "The " showing a lady at full length glancing into a g glass, one hand touching the wall and the other raising the front of her dress in a pose at once d graceful. It is in such designs that the younger re over the old, who won their laurels with sitter's re throne, and who seem unable to produce a pose those time-honoured aids. "The Mirror" has all ose of the old style, but it has a delightful expect motion into the bargain. In the "Goldfish," Mr. with charming grace of line, places his lady at where she watches the movements of golden carp wl. Both these works are pale in tone, but full hoicest colour and light.

king of design in portraiture brings to mind the

work of J. E. Blanche, who certainly excels in this particular. His only picture in the Academy is admirable in this respect, and is a fine object lesson to those who are content to flop a sitter into the regulation chair and take the first arrangement that comes. In execution he has the manner of Sargent without the matter. The drooping right hand of Miss B. Capel might be thought from its gangrenous colour to be dropping away into dissolution. On the whole, however, the colour is fine, if the steely quality of the dress be thought not unpleasant.

Of the five by Arthur Hacker, A.R.A., the portrait of the artist's mother will be judged the best. The lady reclines upon a sofa, her hands clasped upon a newspaper. Simplicity could go no further; but strength goes with simplicity. The reticence and fine feeling of this, its intimate character, and the charm of its Orchardson-like colour, will help on the painter's reputation in a great degree.

A name that deserves to be more widely known is that of H. G. Riviere, whose "Countess of Leitrim" is remarkable for the animation of the expression—truly a "speaking" likeness. The same artist's portrait of Captain Hamilton, of the Fire Brigade, in full war paint of helmet and epaulets, would be rather a terrible thing to hang in a room.

One of the greatest surprises of the year is "An Early Victorian," by William Logsdail. He showed last year how fine a portrait painter of children had been hiding his light under garish Italian views; but this year his little maiden in the costume of our grandmothers is a startling proof of the artist's store of power. It is, naturally, of the school of complete realisation, and in that particular style of work it stands as a perfect achievement, vivid and strong in its contrasts of tone and lovely in colour. Mouat Loudan continues his tapestry-like idylls of portraiture in "Mrs. Sydney Belfield" and "Mrs. Bowles." The former has its charm spoilt by the fact that the seated figure is too closely framed, so that one has an uncomfortable feeling of its cramped imprisonment, and the hopelessness of its ever being able to rise to its full length. The other work is the finer, on the whole. The dignity and seriousness of the handsome elderly face is masterly, and a delightful harmony exists between the lavender dress and the silvery grey hair of the sitter. In such work, and in that of others mentioned, the evident desire of the painters to do more than give merely a coloured record of their subjects lifts portrait painting to a higher level than still-life likeness taking: such a desire adds individuality and a pictorial interest. It may be portrait-painting extraordinary according to the more usual standards: but only along such a line can the art find further room to develop. The "Lady Weber" of Frank Dicksee, R.A., accomplished and faultless as it is, is but ordinary, and that alone is why one sees it passed by without the appreciation that is its due.

George Clausen, A.R.A., makes occasional attempts at the art, but so far he has not added to his great reputation won in another branch. How curious it is that a man treading with steps so firm and unerring and so far ahead in landscape should stumble so much in the path of portraiture, where many an obscure name is found upon works of undoubted charm—such, for instance, as the taking little figure of "Winnie," by W. J. Gibbs.

We should, before closing this article, direct the attention of photographers to what may be called apparatus pieces, of which there are two or three interesting examples. Nor should we be properly loyal to omit mention of his Majesty the King, whom A. S. Cope, A.R.A., has painted as "a man that hath two coats and everything handsome about him." But to the apparatus pieces. The first is also by Mr. Cope, and represents Sir William Perkin. F.R.S., in a black velvet jacket and with a piece of

silk held across his hands of the mauve colour which he invented. The retorts and other paraphernalia make excellent pictorial accessories. Sir William's fine face seems to want life and purpose.

A less ambitious attempt by Miss Spong gives with nice restraint a man who is evidently sitting at his work, though he smokes a pipe at the same time. But the finest of the apparatus series is probably the portrait of Sir Andrew Noble, Bart., K.C.B. He looks uncommonly like the Duke of Cambridge. Attired in a blue overall, he regards with calculative interest a long test-tube which

he holds with perfect naturalness and the ease of common use. We could imagine no portrait more convincingly carried out for the purposes of a scientific society, by H. Harris Brown.

Amongst the water-colours, we like best the lady's dainty works of Miss Mary Gow, who, whilst pushing the medium as far as safety admits in the matter, does not lose sight of its characteristic qualitative charm.

Other works no less deserving of attention and lying beyond the scope of this article.

## AMERICAN IDEAS IN PROFESSIONAL PHOTOGRAPHY.

[The Convention of the Professional Photographers' Society of New York, brief though it was, and free from the formalities which are usually associated with such gatherings, contained one novel feature, due, we are told, to the constructive energy of the President, Mr. Pirie Macdonald. This was a competition in ideas of service to the professional photographers, the results being communicated to a public meeting of the members and adjudicated for the award (of fifty dollars) by those present. We give below the descriptions of such of the ideas which have gained publicity in the columns of the official organ of the society, our New York contemporary, the "Photographer." The fact of a judging body thus constituted is probably responsible for the rather strange idea, that of Mr. Stebbins, for a dark-room sink, selected for the award.]

### Artificial Light Printing Frame.

Mr. Wendell, of Albany, showed a printing frame such as he used in his studios. It was designed for a six-ampere arc lamp run on 110-volt current, or the ordinary incandescent lamp current. The electric light companies supplied the lamps free,

and the printing frames were constructed to carry five or six cabinet frames at once. The cost of current consumed was only five cents an hour, against the 35 cents an hour of the Aristo lamp, and the printing was effected in six or seven minutes. Several of these frames could be used in a studio, turning on one, two, or three, as the work required. The saving was quite considerable over the larger size lamp.

### A Dark-Room Sink.

The sink, bought, or put in by a plumber, of which Mr. Stebbins showed a section, was made of a mixture of cement and sand. A framework of half-inch boards was first built on the supports where the sink was to be placed, and on this a thick layer of cement and sand in the proportions of cement 2 parts, sand 3 parts, was laid, about an inch thick. While this is setting an inner framework of half-inch boards, about 2 in. shorter than the outer one and about an inch shallower and without any bottom, is prepared, and when the bottom layer of cement is set, this inner framework is rested

on it, and the tops of the inner and other framework are steady at an even distance of about an inch apart by little pieces of wood attached at distances at the tops. This forms a space between the two frameworks and the bottom layer of cement and into this mould more cement mixture is poured and allowed to set. The whole forms a most permanent form of sink, the cost of not over \$1.50 for one eight feet long. Mr. Stebbins figured that his sink cost 75 cents for labour and 78 cents for cement. Waste pipes should be put in place before the cement is put in and set a little below the surface of the cement to allow for shrinkage when the cement sets. To strengthen the sink at the sides, corners, etc., tenpenny nails or pieces of steel can be driven into the sink, and, if thoroughly covered, will not rust. A sink could be lined with cement in the same way. The sink showed no signs of damage from chemicals, etc., after use of a year or more, and was thoroughly water-tight and very cheapest possible.

### A Wire-Netting Background.

Mr. Merrill, of Salem, Mass., showed a background covered with wire mosquito netting, grey being the best. Black or white oil paints and grey ground, the only limitations, the photographer has as to his background is in his individual

capacity to carry out his ideas. The mosquito netting can also be used to intercept too harsh a background behind the sitter. The expense of a 6 by 8 piece is about \$3.00. Black or white oil paint is applied with a broad brush right through the mesh.

# Making Pictures the Patron Will Want to Buy.

Evans, of Pittsburg, offered a suggestion from practical sense. Undertake and carry out as far as you can to make sure that your patrons will want to buy. Business on a speculative basis can be carried on most successfully. Evans never lets a print go out of his studio without being fully satisfactory both to the sitter and his or her friends. No action or your money back. There is nothing a man will rather than a good picture of himself. Women are not in men for vanity. In groups of large sizes you never fail to get a picture to every man in the group whose face is good. Never attempt to sell them. The man who pleases his eyes makes money. The man who limits himself to two or three negatives loses out. Make good, and you will not have to about your bank account.

## Control in the Printing Room.

Wendell, of Albany, offered as a second suggestion his method of controlling the work and the consumption of paper in the printing room. He charges his printer with the paper sent to the printing room and makes him account for it. He has 6,200 square inches of paper to the roll of twenty-six feet wide. The system keeps the printer to the mark and benefits him as well as his employer. The system is as follows:—

### REPORT ON PLATINUM PAPER.

Platinum Paper (Black). Roll Nos. 1 and 2. March 28, 1907.

	Amount Cut.	Accepted.	Rejected.	Unprinted.	Waste.	Amount on Hand.
22	4	3	1			12,400 sq. in.
10	20	18	2			Cut 6959 "
8	32	30	2			Left 5,441
7	40	30	7	3		
6	55	40	10	5		
3	29			29	2 in.	
...	180	121	22	37	2 in.	

Notes: Paper is not working well. Is paper fresh? Yes. Are there coating? Some. Condition of weather: Bright and dry. (Signed) JOHN JONES, Printer. Prints average? Good. Are they spotted? No. Are they rubbed? Is the printer getting all there is in the negatives? I don't think he is. (Signed) JIM SMITH, Inspector. Quantity of waste for March 28, 1907, Platinum Paper (Black) 15 per Cent. or less, valued 2-24 dols.

## Hollinger's Suggestion for Children.

Hollinger, in a most humorous speech, gave his methods of drawing the attention of children while under the skylight. He suggested a variety of simple conjuring tricks with bits of paper and pennies, etc. He also recommended the use of glass instead of rubber ones for the children to play with. It is different and new to the kids. These kinds of tricks excited the child and got him into more and better positions than the ordinary whistling birds, etc.

## A Postcard Printing Frame.

Phelps, of Sidney, showed his postcard printing frame, which is illustrated herewith. It is a piece of apparatus consisting of a window-frame arranged to receive the negative and printing paper, and a wooden slide mask operated by the handle which cuts off the light from the negative. One hundred postcards in five minutes can be made with this apparatus. A patent has been applied for it.

g of a window-frame arranged to receive the negative and printing paper, and a wooden slide mask operated by the handle which cuts off the light from the negative. One hundred postcards in five minutes can be made with this apparatus. A patent has been applied for it.

## Macdonald's System of "Following-Up" Orders.

Mr. Macdonald showed his card method of entering orders and following them through until finally disposed of and entered as paid or billed. He showed that, by a good system, it was impossible for any orders to get out of the studio unpaid for or uncharged. He had a set of three pigeon-holes, in the first of which the card was filed as soon as the first sitting was made. As soon as proofs were sent out, this was noted on the card, and it was transferred to the second pigeon-hole. Here it must remain until the order for finished pictures was received. The number of cards in the proof pigeon-hole was a guide to the state of the business. If any proofs stayed out too long it was easy to follow by reference to this pigeon-hole. The card was transferred to the third pigeon-hole when the proofs came back with the order. The cards in the third pigeon-hole had to show what orders were in the house undelivered or unpaid for. The cards themselves were divided up in spaces carrying the usual notices of name, address, date, style, etc., etc., and entirely took the place of the regulation register, which all too soon becomes cluttered up with a number of filled orders, among which it was difficult to find any particular order which might have hung fire for some reason or other.

## A Business Idea.

The Rochester Section of the Society, through Mr. Clarence Smith, submitted for general attention an idea or scheme for drawing a more powerfully distinctive line between professional and amateur photographers.

"As no high-class photographer is in a position to compete with the amateur and so-called 'penny-picture-man,' it is highly important for us to establish a certain standard as to size as well as artistic merit in our work. We would suggest that no 'bust size' portrait sold by the dozen should measure less than 1½ inches from the top of the head to the bottom of the chin, and that the better workers in the larger towns shall absolutely confine themselves to 5 by 7 plates or larger, and produce an article in photography that will command a price based upon intrinsic worth or value, and not upon any popular price basis, which latter undesirable basis is the only one on which, and with which, all the 'cheaper workers' exist and flourish."

"Let us coin two new names, one 'Portrait Size,' made by professional portrait photographers, which should be given to all prints on 4 by 6 paper, and the other 'Amateur Size,' which should be applied to all smaller work, made by photo men or amateurs, and let these distinctive names be constantly advertised and emphasised by all the worthy members of our many state associations as distinguishing and classifying the difference between the work of the professional portrait photographer and the so-called 'amateur' or 'penny-picture-taker,' and we feel reasonably sure that within a fairly short length of time the general public would be thoroughly educated to clearly note the distinction between professional portraits and amateur workmanship, and would gladly appreciate the difference in the cost price of the two productions, thus settling one of the present troublesome questions of our artistic profession."

## An Enlargement Method.

Mr. Rockwood was not a candidate for "golden honours," though his suggestions are of great value to the fraternity. He referred to his method of making enlargements, which has been wonderfully successful in his own studio and been adopted by others with great satisfaction. His point was to make the positive at once to the size of the desired large negative; then, after retouching, accenting, or alteration—which can be done to almost any extent—the large negative can be made in the dark-room by superposition, preferably in a printing frame. The cost is a trifle more, but the results amply justify the expense, as there is no suspicion that the negative is not direct from life. Mr. Rockwood's excellent 8 by 10's of children are all made from instantaneous cabinet-sized negatives.

## EXPERIMENTS ON THE LATENT IMAGE.

(A Paper read before the Paris Academy of Sciences.)

THREE facts have long been known:—1. That a photographic plate, treated with potassium bichromate, washed and dried, and exposed behind a negative, may be developed in full daylight, a reproduced negative being obtained. 2. Prolonged exposure to light affects the latent image in such a way that there is reversal on development. 3. That the film, when exposed in the presence of oxidising bodies, is particularly liable to reversal.

I propose to consider the action of weak oxidising agents on the latent image—not such as are used for its destruction, but those which form a new combination with the latent image which permits of distinctions being made as to the constitution of the latter.

When a plate which has received an exposure is placed for a few minutes in a one per cent. solution of potassium ferricyanide, and is rinsed and developed in hydroquinone, potash, and sulphite, two facts are noticed. The first is that the plate may have been very greatly over-exposed without the developer being any the quicker or the result being any the worse. The oxidising agent plays the part of a regulator of the exposure. The second fact is that if one develops by the unscreened light of a candle the result obtained will be negative instead of positive, as it would have been by red light. Reversal thus takes place, even after a very short exposure, but a stronger image is obtained after a more lengthy exposure.

These facts, it would seem, should be distinguished from those known as solarisation, although this phenomenon is always the characteristic of a prolonged exposure.

The regulation of the time of exposure by means of an oxidising agent can be applied to certain bromide papers—for example, to the "Orthobrome" paper of the firm of Gevaert, of Anvers. The only necessary precaution is to add five per cent. of glacial acetic acid to the oxidising solution.

### A NOTE ON THE ABOVE PAPER.

It is quite possible that there may be some hidden principle or value in M. Demole's experiments, but at first sight the facts as cited by him are not inconsistent with the ordinary phases of solarisation.

Dealing first with his statement as to the treatment of an over-exposed plate with ferricyanide, it would be as well to point out that this is not a newly observed fact. It has been pointed out by Sterry (1899), Lüppo-Cramer (1901), Schaum (1903), and Eder (1902), that any oxidising agent destroys the solarised silver bromide image and leaves behind that on the normal silver bromide. This being the case it is obvious that the developer will not be any the quicker nor the result any the worse. Can it be said, therefore, that the ferricyanide is "a regulator of the exposure"? The second observation (that a negative is obtained instead of a positive when developing is effected by candle-light instead of red light) merely confirms a fact that has long been known, and which we personally have applied before now for obtaining a positive or reversed negative, and that is that as soon as development has proceeded to some extent by red light a flash of white light will reverse the image.

Exactly how these facts differ from solarisation is not clear. That the procedure can be applied to bromide paper is a natural corollary, and, speaking from personal experience the slower the sensitive salts the more successful this method of reversal.

Dealing with the prolongation of exposure, one should bear in mind that Janssen pointed out that there were successive stages with prolonged exposure, and that to obtain a second negative image from a primary negative required an increase

If the exposure is prolonged above a certain limit the plate undergoes a second reversal, the inverse of the first. Thus using a Lumière "blue label" plate behind a negative at from an arc lamp a good positive copy is obtained in one when development is done in red light. With increased exposure the plate is oxidised, and on development in white light the result of from one second to 170 seconds' exposure is reversed, i.e., a negative. From 180 seconds' exposure, development at first a positive, which, little by little, with increased exposure, becomes negative. From seven minutes' exposure the positive still shows, and does not distinctly alter, but the lights are not clear. From fourteen minutes' exposure the positive is persistent, and one has, in a way, realised the sought-after problem of development in daylight.

If it is assumed that the latent photographic image consists of a silver sub-bromide,  $\text{Ag}_2\text{Br}$ , resulting from the decomposition of light in the presence of a bromine absorbent, such as gelatine, the sub-bromide, being a very unstable body, is readily oxidised to an oxy-bromide of the formula  $\text{AgOBr}$  according to the hypothetical equation:—

This hypothetical oxy-bromide of silver, oxidised by the action of the developer alone, is more easily reduced than the combined action of developer and light, but is less quickly reduced by the surrounding silver bromide which has not acted upon. Hence it is that the latent image being so, and its immediate surroundings not so, the image is reversed. It should be said, in conclusion, that the hypothesis which in this reaction into account is based on the existence of a sub-bromide as a constituent of the latent image, an assumption yet to be proved.

E. DEMOLE.

in exposure of 100,000 times the normal. This statement has also been confirmed by Eder, who, using a Chapman-Jones sensitometer plate, finds that (assuming that a vigorous half-toned negative required an exposure of one to two Hefner camera-meter-seconds) a distinct reversed positive required an exposure of 300,000 H.c.m.s. Thus the exposures given by M. Demole of fourteen minutes are much below this limit. True, he says that with this exposure and subsequent treatment with ferricyanide "one has, in a way, realised the much-sought-after problem of development in daylight"; but, by the well-known principle of utilising an oxidising agent he would have destroyed his solarised image, or, to put it in other words, have rendered it incapable of being developed. The result must be the reverse, positive, because the bromide of silver that is left in a developable condition is the inverse of the negative image.

There is also one other action which M. Demole recognises in the case of bromide paper, but not in the case of the plate, and that is the action of the ferricyanide on the gelatine itself. This it is well known is a hardening action, and it might be taken into consideration. Further than that, one must also assume the possibility of some interaction between so powerful an oxidiser as ferricyanide and the hypothetical silver sub-bromide, which, as Dr. Homolka suggests, can be easily split into  $\text{Ag} + \text{AgBr}$ . This being the case, one may be reminded as pointed out by Dr. Sedlacek in his work on toning bromide with ferricyanides, and by Mr. Douglas Carnegie in his article on "The Chemistry of the Sulphide Toning Process" ("B.J.P.", p. 907, p. 676), a complex of silver ferrocyanide which would be impermeable to a developer.

th regard to the author's equation, we must take exception is on precisely the same grounds that led us to pen our in our issue of the 19th ult.  
Demole's experiments are easily carried out, and therefore

me may feel tempted to repeat them. Hence the above es are written merely to try to explain the observation by t is known rather than search for what seems a somewhat strained reading.

## THE ISOSTIGMAR LENS AND THE PETZVAL CONDITION.

The following report of the discussion which followed Messrs. Beck's paper before the Royal Photographic Society, continues the rest of the paper itself published in the last two issues. It is addition to the properties of a flat field anastigmat will be taken

Beck's paper before the Royal Photographic Society, continues the rest of the paper itself published in the last two issues. It is and discussed by other opticians.—Eds. "B.J."]

D. CHALMERS said that he was particularly interested to notice in this new type of lens Messrs. Beck had departed rather than was usual from the Petzval condition. It could be proved for absolutely perfect correction over a small field, the Petzval condition must be satisfied. The correct statement of this condition is that the sum of the focal powers of the individual surfaces, when added by the product of the refractive indices on either side of the e, should be zero. When this sum was not zero, it gave the ure of field, provided a certain choice was made in cases where atism was present as to what should be called the focus. er of the focal lines, nor the circle of least confusion, would r to this requirement; but a point as far from one of the focal as the confusion circle would answer, and the curvature of the passing through such points could be calculated from the sum Petzval terms. He pointed out, however, that the effects of tions of higher order must be considered, and admitted that, ards these terms, no simple expressions had as yet been put d, and the elimination or reduction of their effects was one of oubles of the designer of photographic lenses. With any definite tions of this order there would be a most suitable value for the ponding aberration of the first order, and even with favourable tion of aberrations of higher order, there was a definite limit possible departure from the Petzval condition depending on the rd of definition required, the aperture and angular field. When tigmatism was perfectly corrected the maximum amount of ure of field might be reduced to be half the amount calculated he Petzval condition, for the actual field at which this maxi- occurs, or one-quarter the amount calculated for the angular t which the focus actually came back to the true focal plane- g the actual lens as described by Mr. Beck, this angular value e be found to be about 32 deg., and the departure from the as calculated from Petzval's condition, would be four times ual value of the greatest departure. Thus, assuming the astig- n to be corrected, the possible departure from the Petzval con- was four times the amount which would be obtained if one disregard aberrations of higher order. Allowing astigmatism able amount and type a still greater departure was possible. halmers was much interested in the series of diagrams thrown screen which illustrated the curious ways in which aberrations her order might affect the definition. He had worked out the e of the various aberrations of higher order, and it was curious erve that some of the lenses showed a large amount of one e of these aberrations.

Frederick Cheshire: I am afraid that my contribution to this g's discussion will be a very modest one. By the courtesy of thors I have had the privilege of looking through their paper rance, and I have been particularly struck by the fact that an ain note runs through it as to what the Petzval condition is. I thought then that I could not do better than go to one sources which is not easily accessible, and see what Petzval ly did say about his famous equation. It is very short indeed. rticle is entitled "Fortsetzung des Berichtes über optische suchungen," and is to be found in the "Sitzungsberichte der mie der Wissenschaften z. Wien," Vol. XXIV. (1857), on -6. The following is a somewhat free translation:—  
The value of the reciprocal of the radius of curvature at the vertex curved surface upon which a picture is produced by a lens nation is independent of the [lens] curvatures, and is equal sum of the products of the values of the reciprocals of the lengths into the values of the reciprocals of the refractive s; or, calling the radius of curvature of the picture R,

the focal lengths of the separate lenses  $p_1 p_2 p_3 \dots p_m$ , the refractive indices of the different media of which they consist  $n_1 n_2 n_3 \dots n_m$  then the following equation holds, viz.:—

$$\frac{1}{R} = \frac{1}{n_1 p_1} + \frac{1}{n_2 p_2} + \frac{1}{n_3 p_3} \dots \dots \frac{1}{n_m p_m}$$

"The principle as well as the formula, which is the expression of the same, remains true if one or several of the lenses are replaced by a mirror or mirrors, the refractive index for each mirror being taken as equal to one. In this general formula the lens curvatures only come in so far as they are contained in the focal lengths  $p_1 p_2 p_3 \dots p_m$ , but the intervals, on the other hand, do not appear, so that it is only necessary to consider the lenses and mirrors of which such a combination consists without taking any account whatever of their manner of arrangement. For this reason we have a method of determining the curvature of the picture surface.

"In considering the limits within which this important principle is true, it should be noticed that it is not necessary that the lenses and mirrors should be spherical, because the equation given above is derived as a special case from the following general equation:—

$$\frac{1}{R} = \frac{n_1 - 1}{n_1 \tau_1} + \frac{n_2 - 1}{n_2 \tau_2} + \frac{n_3 - 1}{n_3 \tau_3} \dots \dots \frac{n_m - 1}{n_m \tau_m}$$

where  $\tau_1 \tau_2 \tau_3 \dots \tau_m$  are the radii of curvature of the respective surfaces of rotation, taken at the vertices, and  $n_1 n_2 n_3 \dots n_m$  are the refractive indices of the media at them."

Mr. Beck's question is thus answered. It is not the equivalent focal lengths of thick lenses which must be put in the equation

$$\frac{1}{R} = \Sigma \frac{1}{n f}$$

but the refracting powers simply of the various surfaces. Perhaps the least easily misunderstood form of Petzval's equation is that given by Czapski, viz.:—

$$\frac{1}{R} = \Sigma \frac{1}{\tau} \Delta \left( \frac{1}{n} \right)$$

i.e., the curvature of the image surface at the vertex is equal to the sum of the products obtained by multiplying the curvature of each refracting surface by the difference of the reciprocals of the refractive indices of the bounding media. Finally, I would point out that Petzval's equation does not give the curvature of the image surface over an extended area, as Mr. Beck appears to assume, but at the vertex only.

Mr. F. J. Selby: While congratulating Messrs. Beck upon their new lens, I do not entirely agree with what they have said about the Petzval condition, but neither do I altogether disagree with it. It is a matter for congratulation that the remarks they have made about the Petzval condition have been made in such a way that attention is certain to be drawn to the subject; the point at issue is one of interest and importance. I need not say anything further as to what is the accurate statement of the Petzval condition, for it has been put very clearly on the blackboard by Mr. Cheshire. The state-

ment, however, can also be put in the form:  $\Sigma \frac{1}{\mu r} = 0$  where  $r$  if the radius of the curvature of either surface bounding the medium of refractive index  $\mu$ , and the summation is extended over each surface bounding each medium, the proper signs being given. In this form there is no ambiguity. With regard to the accuracy of the Petzval condition, the statement that  $\Sigma \frac{1}{\mu f}$  gives the curvature of the focal surface is only true when we add that it gives the curva-

ture of that surface at the point where the axis of the lens cuts that surface, or at what I may call the vertex of that surface. The statement necessarily will only hold good and give exact results over a comparatively small angle. It cannot be applied over so wide an angle as is considered in the measurements which are recorded in this paper. The statement with regard to the limits of accuracy of the formula has been made very clearly by my friend, Mr. Chalmers, and affords some new and interesting information regarding that formula. One cannot expect that the Petzval formula gives complete information as to the curvature over so large an angle as 35 deg. If the formula is applied up to an angle of 15 deg. or 20 deg., I think one may see from the curves which were shown on the screen that the departure from truth up to that point is not very great; not larger than might reasonably be expected when one takes into account the fact that other factors have necessarily been adjusted to counteract the curvature to be expected from the non-satisfaction of the Petzval condition, and at this angle are already beginning to affect the result. I have worked out the amount of departure in the "Isostigmatic" curve from a flat surface at 15 deg. and 20 deg., taking the curvature at the centre, as given in this paper, by the Petzval formula, as 25 inches. The curvature at 15 deg. is .07 inch. I do not know what it is actually in the case of this lens.

Mr. Horace Beck: It is .04 inch.

Mr. Selby: And at 20 deg. I find the departure from flatness, according to the Petzval formula, to be .14 inch. Mr. Beck, in his paper, gives the maximum departure for the actual lens as .09 inch.

Mr. Beck: At 20 deg. it is .07 inch.

Mr. Chalmers: The one-quarter refers to the calculated value of the Petzval terms near the edge of the field; in fact, at the place where the two curves actually cross the focal plane.

Mr. Selby: That would appear to agree very well with the results of some of Mr. Chalmers' work which he has just communicated to me, as to the ratio between the actual curvature and the curvature given by the Petzval formula, when the Petzval condition is not satisfied.

Mr. Conrad Beck: In order to stimulate further discussion, I may perhaps say a word or two before my brother makes his reply to the questions which have been raised. In my opinion, Mr. Selby's explanation does not approach the real question. If the Petzval condition is simply an approximation that only refers to a few degrees on either side of the axis, it is evident that it is a useless condition to consider in making photographic lenses, which are instruments in which a considerable angle is used. I do not think that the Petzval condition has been generally understood to be limited and to apply only over such a small angle as Mr. Selby suggests; but even were this so, our new lens is corrected for the small angles near the axis. The condition as put forward by Coddington was applied to a considerable angle. The proof we have in Coddington's work is a complete one, advanced step by step, and covering the entire point. We have no reason to suppose that Coddington intended the Petzval condition to apply only to a few degrees, and although certain approximations are employed by him, they are only inserted in the small quantities of the second approximation. There is no suggestion of further approximations, except in the earlier portions of Coddington's work, which, however, might have a serious influence upon the matter. But if we take Von Seidel's five conditions—spherical aberration, coma, astigmatism, curvature of field, and distortion—we find them stated as being inter-dependent, and to be satisfied in that order. If the fourth condition is only to be the first approximation, which it certainly is not, it is one that would be of no use for photographic purposes. The nature of the curve of the anastigmatically corrected field that is generally found in anastigmatic lenses is not a circle—it is a wavy line. Mr. Chalmers was the first to point out that the Petzval condition need not be entirely satisfied. We are rather inclined to think that the true condition which governs astigmatism would be very complicated and not simple like the Petzval condition. Mr. Chalmers hints at a method of setting back the curvature of the field so that we can obtain a residual error equal to one-fourth of what would be expected if the Petzval condition were correct. We are anxious to see this point elucidated, because if that portion of the theory of lenses could be worked out we should be one stage nearer providing opticians with a working hypothesis. We have got beyond the point where the Petzval condition suffices for making photographic lenses, and we are ready for a further condi-

tion; as opticians, we are not prepared at the present time to accept Mr. Selby's explanation of the error, because, although our new lens does not approximately fulfil the Petzval condition, the anastigmatically flat field is obtained both at small and at large angles.

Mr. Chalmers explained that he had not intended to put forward any method for bringing the field back to the focal plane.

Mr. Selby: May I make my position clear? I think there is no doubt as to the usefulness of the Petzval condition. If the Petzval condition is not satisfied, then the field will not be flat, and curvature will be determinable within certain limits. Beyond limits other factors may come in, and I think Messrs. Beck have done useful service in showing that too rigid an observance of the Petzval condition may not be always desirable.

Mr. Lan-Davis said that he had been specially interested in the question raised respecting the Petzval condition. In Von Seidel's research on the design of photographic lenses, it was clearly demonstrated that in taking a first approximation it is necessary to satisfy algebraic conditions, of which the Petzval condition is the first. The fulfilment of these five conditions only removed aberration of the first order, such as arose when using narrow-angled pencils. Very wide-angled pencils were used, other conditions of much greater complexity must be fulfilled. This was well illustrated in the case of central spherical aberration, for it is well known that a great deal of this aberration remains in lenses of large aperture after the Seidel condition has been fulfilled. The Petzval condition has a similar bearing on flatness of field. In constructing photographic lenses aberration of first order might be got rid of by fulfilling the five Seidel conditions, but, when finally correcting, these conditions had to be somewhat departed from. In other words, it was necessary that the Petzval condition should be fulfilled in order to produce lenses without aberrations of the first order, but afterwards the Petzval condition might be somewhat departed from and aberration of higher order eliminated, while the field of the lens remained flat.

Mr. C. P. Butler said that as this was a new lens he might ask the usual question as to the permanence of the glass. He believed it to be a fact that certain specimens of Jena glass were undoubtedly deteriorating with time, and although it could be cleaned, it was causing a good deal of trouble. He did not know whether it was stated what was the degree of apochromatism for the central ray, but presumed that it was perfect for that ray, and it would be interesting to know to what extent the secondary spectrum had been eliminated.

Mr. E. J. Wall asked whether the particular rays for which the lens was corrected were those which would affect colour work. He was thinking particularly of photographic three-colour work, and desired to know whether the lens was what was generally called an apochromatic for that purpose.

Mr. J. W. Gordon said: The difficulty which has chiefly been discussed—affecting in this instance the application of the Petzval condition—applies not to this particular matter alone, nor even to photography generally. In all cases in which we apply exact mathematical formulae to practical ends we invariably find that there are limits beyond which a formula will not hold, and it very often happens that a useful formula applies only in a very limited sphere. Therefore, I fancy that the difference of opinion which has been brought out in the course of this discussion is one rather of appearance than of fact. Nobody would suggest that this Petzval condition does not apply in the vertex of the field, and nobody would suggest, apparently, that it holds in the edge of a widely extended field. It does not follow from this that the condition is useless. Mr. Beck says, in effect, that the Petzval condition is of very little use to him in endeavouring to secure a good lens for wide angles. He wants something which will carry him over the field. He wants a pure and definite mathematical value to be elaborated into the form in which it is adapted to the practical work of the optician. He wants a general form of the algebraical expression which he can apply without restrictions; in other words, a round trip ticket which will carry him as far as he wants to go. We can all agree upon the desirability of that. It is very likely that to the end of the story the best way of solving the practical problem will be to set to work as Messrs. Beck have done, first of all to provide an extremely accurate observing instrument, and then to proceed by the old but not yet superseded method of trial and error.

The Chairman: The discussion seems to show that photograph

is largely a matter of approximation, and that it is not at present to be very definite—at all events, as regards any optical aspect of the matter. I should like to ask whether the lens is achromatic for the enclosed arc—how far it is corrected for violet light.

Horace C. Beck, in replying to the questions which had been asked, said that if the matter were merely one of approximation he only say that some people's ideas on the subject of approximation were rather wide. Mr. Beck instituted a comparison between a near lens and his new anastigmat, pointing out that with the very curved field which was practically free from astigmatism he obtained if the lens was specially constructed. By means of tests on the blackboard he showed that, theoretically, according to Petzval condition, in his new anastigmat lens there should be one-half the amount of curvature which the rectilinear lens when the astigmatism was corrected. He considered that the distortions in the shape of the lenses and the curves were quite sufficient to upset the practical results of this calculation on the lens; he certainly thought, in view of the enormous amount of astigmatism which was caused in a rectilinear when the attempt was made to have the astigmatic field on to a flat field, it was remarkable that the theoretical curvature in the Isostigmat lens should work out at all what there was in a rectilinear lens.

Chalmers asked at what angle the astigmatism and curvature were exactly corrected?

Beck said that it was near the 35 degrees fourth axis. In answer to Mr. Butler's question, Mr. Beck said that the negative lines were made of ordinary silica glasses. With regard to the chromatic aberrations, he could only say that the lens was ordinarily corrected for photographic work, but not specifically for three-colour work. It indeed be good enough for that already, but he had not tried it. He would recommend it so far as ultra-violet light was concerned, but not for the red end of the spectrum. He had no doubt that for arc work it would prove satisfactory. With regard to Gordon's remarks about the "round trip ticket," the attainment of a more definite formula would undoubtedly be of use, if it only be relied upon. In his personal work he found that he did not limit himself or tie himself up by considering the Petzval condition. He advised workers to try that plan first of all, and then if they failed to consider the Petzval condition. But his experience was that the Petzval condition was not of much assistance even in preliminary calculations.

#### THE HOODED LENS IN TELEPHOTOGRAPHY.

In reference to the paragraph describing the recommendation of Captain Owen Wheeler to employ a hood of considerable length as a preventive of veil in telephoto-work, we are able to reproduce four

Fig. 1.

The Green, Weybridge. Positive lens only, Beck Isostigmat 7.2 in. focal length.

photographs from negatives by Captain Wheeler, which, as they lie before us, very fully bear out his claims for the advantages conferred on the negatives as regards brilliancy by the use of such an

attachment, and even the half-tone reproductions, which in the hand proofs convey very well the effect of the half-plate prints, should show the reader that flatness and veil in telephotographs is to be regarded as a defect just as much as in other branches of photography. In making the four exposures successively the positive lens in each case has been Messrs. Beck's new Isostigmat—viz., the 7.2in. lens of Series III.—an instrument of which Captain Wheeler writes to us in most appreciative terms, and his praise, coming as it

Fig. 2.

Telephotograph, five magnifications, Isostigmat positive, stopped to  $f/16$ , Voigtlander negative, 2.6 in.

does from one practised in the critical work of telephotography, is a notable testimonial to the new lens. The exposures were made in the windy weather of Saturday, May 4, with a maximum camera extension of 15in. The prints are straight, untouched duplicates of the negatives. In reproducing them, we may quote Captain Wheeler's own opinion of the advantage of the hood from his article in the "Pall Mall Gazette":—

"It is safe to say that much of this deterioration in the quality of telephotographic negatives, as compared with negatives obtained with ordinary lenses, has been due to what are known as 'internal

Fig. 3.

Telephotograph, nine magnifications, Isostigmat positive, Series II, stopped to  $f/16$ , Beck negative, 1.2 in.

reflections.' These in an ordinary photographic objective can usually be disregarded, but in a telephoto system they become very serious. The light enters the latter, when one is working at any but very low magnifications, at an extremely small angle, and, accordingly, the interior of the lens mount is illuminated quite sufficiently to interfere with the proper formation of the image on the sensitive plate, and to cause fog. These internal reflections have been variously dealt with by opticians who realised their objectionable

capabilities. The usual method has been to place diaphragms, or 'stops,' in the lens tube with the object of intercepting the redundant light. In another case a partition has been introduced in the camera, and the 'negative' element of the telephoto system screwed into it, instead of into a lens mount, the bellows space remaining between the negative lens and the camera front which holds the 'positive' being regarded as a trap for the internal reflections. In all these cases, however, there is the disadvantage that the internal reflections during exposure are still in the system all the time and every time. In the case of the partition camera, it is obvious that any improvement secured must be at the expense of an appreciable increase in weight and bulk.

Fig. 4.

Telephotograph, thirteen magnifications, Iostigmat positive, Series II, stopped to  $f/16$ , Goerz negative, 1.2 in.

"A more simple and certainly very effective remedy for internal reflections has been worked out by the writer, who for many years has been interested in the application of photography to military purposes, but who, until a month or two ago, was baffled by the difficulty and uncertainty surrounding telephotography at high magnifications. The idea consists in the use of a specially constructed and very extended hood, sometimes about a foot long, which is attached to the lens mount, and the length of which is adjustable at will. The difference which this appliance makes in the quality of the negatives, in ease of working, and in latitude of exposure is very striking, and there is reason to believe that the practice of telephotography in general will receive a decided impetus by the habitual employment of the telescopic hood to overcome the nuisance of internal reflections."

#### A POINT IN ORTHOCHROMATICS.

DURING the past session the Croydon Camera Club has experienced a wave of orthochromatism, lectures and demonstrations on this subject having loomed large in its programme. The last to administer a heavy dose of orthochromatic wisdom was Mr. E. A. Salt, who on the 24th ult. substituted some remarks on this subject for a description of a new shutter-tester.

The point raised by Mr. Salt in his own words is as follows:—When working in the past with orthochromatic plates and filters I have always been struck with some subtle difference, difficult to define, in the negatives produced by their aid, as contrasted with results obtained on ordinary plates, this being quite apart from any question of better rendering of colour values in monochrome. A recent series of exposures on screened ortho plates, ranging from quarter-plate to 12 x 10, has again brought the matter forcibly forward, and a careful examination of the negatives leaves no doubt at all in my mind that the difference is one of "quality." In the case of the larger negatives this difference may be expressed as akin to that which can almost invariably be detected when comparing an enlarged negative with one taken direct, or, in other words, they

had a sort of "process" look. Now just for a moment let us consider what is, in nine cases out of ten, meant by a "high class" or "quality" negative in professional or trade circles. It is, of course, essential that it be within the range of the printing process employed, though it need not necessarily print its entire scale; it must have sparkle, life, and go, coupled with tender gradation everywhere, gradation as only a photographic process can give it. I am quite aware that I am using the somewhat indefinite term "quality" in a restrictive, and even meretricious, sense; good qualities may, and do, exist in other directions, but so long as the sense in which I am employing it is understood, it will be sufficient for the present purpose. This brings me directly to the point I wish to touch before you—viz., when it is desirable, or undesirable, to use orthochromatic plates and filters. If we wish to retain in our negatives the characteristics indicated, then I think it will at least be worth while to omit the filter. Its employment has a distinct tendency (I do not wish to put it any stronger than this) to knock the life out of a picture, to flatten it, and to lose much of the infinite gradation and subtle play of light which adds so much to its charm. When the light is yellow, as in late evening, we have here the equivalent of a filter in position, and we must consider whether an ordinary orthochromatic plate will give us best what we require. It may be that the filter, under normal conditions, only accentuates what is inherent in the ortho plate, and if this is so, it is an open question whether it will, under every condition, do all that an ordinary plate is capable of; that it will do far more on occasions is, of course, obvious.

We have from time to time seen very fine flower studies on orthochromatic plates, and I believe I am correct in saying that some of our best floral photographers never use any but ordinary plates. It can hardly be conceived that this is purely due to an innate conservatism. The choice is probably deliberate, assisted by the fact that they can avoid heavy colour contrasts. In portraiture how many professionals employ colour sensitive plates? Very few. The retoucher can remove blemishes due to freckles and the like, and the ordinary plate will, in the majority of cases, give satisfaction to the public.

I do not wish it to be understood that I in any way wish to depreciate the use of orthochromatic plates and filters, or that I do not appreciate the notable advances recently made in their manufacture. Brilliance and sparkle, however desirable in some cases, must not be set up as a fetish or regarded as the ultimate aim of the pictorial photographer. Their suppression, indeed, may be a positive advantage, irrespective of colour translation. Again, there are subjects and effects in nature which can only be satisfactorily translated into monochrome by employing ortho plates and filters, such as which no ordinary plate could possibly hope to deal with, and should accordingly be grateful to the plate-maker for having so well extended the scope and possibilities of our art.

On the other hand, there has been a distinct tendency here to orthochromatism run away with us. Two pictorialists, for example, set out on an expedition together, one armed with ordinary plates, the other with orthochromatic, and adjusted filter. They may expose on the same subjects, and will compare prints afterwards. The orthochromatic gentleman cheerfully chortles with joy on finding out that his confrère's, and that he has secured a possibly altogether unsatisfactory, entirely absent in the latter's print. In vain the owner of the ordinary plate meekly urges that, taken as a whole, his print is more satisfactory, judged by usual standards; the falsity of his rendering pointed out to him in gently modulated accents of an inferiority, and he subsides crushed, if not convinced. There really is no reason why our not altogether imaginary friend should be so convinced, for literal truth is of no moment whatever in a picture, whether it be photograph or painting. "Values" always are, and ever must be, important, and ordinary plates, in the great majority of cases, can give these adequately.

In reply to questions, Mr. Salt said he thought it was a mistake to employ ortho plates when ordinary plates would suffice. Quite apart from the point advanced in their favour, the latter were more easily worked, and presented certain other advantages in practice. In cases where the subject pointed to the desirability of using colour-sensitive plates and filters, then it would be foolish not to take advantage of the added power they placed at the operator's hands.

## Exhibitions.

### PHOTOGRAPHIC SOCIETY OF IRELAND.

THE exhibition which opened at the gallery in Molesworth Street, Dublin, on April 29, contains many good things in both members' and open classes. The hall in which they are arranged has been tastefully decorated, the walls being hung with drapery of two delicate tints of green, whilst the pictures are, as far as possible, could be effected, divided into sections by means of panels, the whole being surmounted by a frieze. Class C, according to "Freeman's Journal," is very strong in flowers. Mr. J. B. Anderson has carried off the silver medal in this department for his truly artistic portrayal of bramble blossom (No. 5). The bronze medal has been accorded to Mrs. F. Perry for the charming picture to which she has given the poetic title, "Loveliest of lovely things are they on earth that soonest pass away" (No. 7). "Onions" (No. 8), by Mr. T. K. Hackett, is a realistic presentation of those useful, if rather humble, products of Nature. Mrs. Heenan's "Bridge of Sighs" (No. 15) cannot fail to attract considerable attention; the water is magnificently done. Mr. R. T. Crook's "Muckross Abbey" (No. 16), Mr. S. S. Rea's "East Window, Ennis Abbey" (No. 13), and Mr. Hugh Pollock's "Sculpture from the Portal of St. Pierre, Moissac" (No. 21) are also certain to be much admired. The silver medal in class A has been secured by Mr. Harold Jacob for an excellently executed picture, entitled, "Place St. Remi, Dieppe," "Sunshine and Mist" (No. 48) is well worthy of the bronze medal which it gained for Mr. John B. Anderson. A similar distinction has been accorded to Mr. T. K. Hackett for "The Islands, Howth" (No. 69). Lambay is beautifully limned. "An Impression of Glendalough" (No. 66), by Mr. Harold Jacob, conveys to the fullest extent the poet's conception of gloominess. "Mist and Thaw in College Green" (No. 63), by Mrs. Mahony, and "On the Liffey" (No. 74), by Miss Elsie Curran, are finished specimens of excellent photography. In class H Mr. C. W. Pearson scored a signal success by being allotted the silver medal, and also the Werner Medal (awarded to the best picture amongst members' classes) for his "Head of a Young Girl" (No. 86). Delicacy and neatness are characteristics of Mrs. D. Mahony's "The Never Never Land" (No. 108). The artist was thoroughly titled to the bronze medal it obtained. Class X., the exhibitors of which are novices who had not previously won a prize, is very interesting. No. 111, "Deserted" (bronze medal) by Mr. W. S. Gosse, is touchingly sympathetic. Class F, open to residents in Ireland who are not members of the Society, is replete with good conscientious work. No. 159, "Landing the Catch" (silver medal), by Mr. Hugh Cochrane, jun., affords a life-like presentment of a fisherman's scene. Artistic perception is palpable in Mr. Robert Low's "A Ray of Light" (No. 127) (bronze medal). Mr. James B. Doran's "Bellast Night" (No. 154), is conspicuous owing to the acceptable style in which the dome of the new Town Hall is rendered darkly visible. No small amount of attention will be devoted to the array of exhibits in the open class, representative of South Africa, Germany, France, India, etc. The collection is of a high order. Mr. Louis G. Hele was deservedly awarded the silver medal for that weirdly impressive conception, "The Garden of Allah" (No. 211). The distinction of being the recipient of an extra silver medal fell to Mr. Henry J. Comley for a three-colour carbons picture "A Corner of the Larder" (No. 240). Various vegetables are strikingly shown in the hues with which Nature endowed them. No. 234, "Waterfall the Moor" (bronze medal), by Mr. J. M. Whitehead, is instinct with rare picturesqueness.

A notable feature of the exhibition is the collection lent by Herr Ehrkoop, the eminent Hamburg photographer. It embraces twenty-seven prints, all of which will more or less awaken the interest of visitors, particularly those which delineate children. A. Holsley Hinton, editor of the "Amateur Photographer," is the judge, and showed two of his works, "On the Moors" and " Windsor Castle."

**SOCIETY FOR COALVILLE.**—An effort is being made to form a photographic society at Coalville, Leicester, for the mutual assistance of members and the encouragement of photography as a hobby.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents were made between April 22 and April 27:—

**STEREOGRAPHS.**—No. 9,260. Method of producing stereoscopic photographs in sheets. Gilbert Dyas, 9, May Street, Dublin.

**CAMERA.**—No. 9,268. Improved magazine camera. Thomas George Goodwin, 3, Avenue Road, Hammersmith, London.

**COLOURING FILMS.**—No. 9,306. Machine for mechanically colouring cinematograph films. Reginald William James, 1, Queen Victoria Street, London.

**MEASURING DISTANCES.**—No. 9,362. Improvements in instruments for optically measuring distances. Optische Anstalt C. P. Goertz Akt.-Ges., 31, Bedford Street, Strand, London.

**SINGING AND SPEAKING PHOTOGRAPHS.**—No. 9,391. Improved method in relation to, and connected with, the taking and exhibiting of singing and speaking photographs for entertainments. George Robson, 21, Rochdale Road, Leyton, Essex.

**AERIAL PHOTOGRAPHY.**—No. 9,433. Improvements in apparatus for aerial photography. Sydney Thomas Williams, 54, Bouverie Road, Stoke Newington, London.

**AERIAL PHOTOGRAPHY.**—No. 9,445. Apparatus for obtaining photographs from balloons or kites. John Edwards Capper and Griffith Brewer, 33, Chancery Lane, London.

**OPTICAL LANTERNS.**—No. 9,484. Improvements in or relating to optical lanterns. Robert Thorn Haines, Chancery Lane Station Chambers, London.

**ILLUMINATING APPARATUS.**—No. 9,574. Improvements in illuminating apparatus, more particularly for use in photography. Jean Schmidt, 31, Bedford Street, Strand, London.

**PHOTOGRAPHIC ART.**—No. 9,699. Improvements in the art or profession of photography. Frederick Scrivner, 2, York Avenue, Manley Park, Manchester.

**CINEMATOGRAPHS.**—No. 9,759. Improvements in and relating to cameras for cinematograph films. Leo Kamm, 27, Powell Street, Goswell Road, London.

**EMULSION.**—No. 9,855. Process for producing an emulsion of phosphate of silver. York Schwartz, 77, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**FOLDING STEREOSCOPE.**—No. 24,404, 1906. Attached to the stereoscope *a* is a handle *c* to enable the apparatus to be held in the hand when in use. At the back *a* is hinged at *d* a piece of wood or other suitable material *e* on which slides a sleeve *f* of wood, at the outer end of which is a block *g* having a groove to receive

the picture *h*. The sleeve *f* is made movable on the piece *e* to form a focussing slide. *i* is a block secured to the stereoscope *a* to form a support for the focussing slide when the instrument is in use. When not in use the instrument folds up and lies flat.—John Stott, 89, Grange Park Road, Leyton, Essex.

**CAMERAS.**—No. 8,788, 1906. The invention relates to the design of a camera which shall be capable of being folded up into a thin flat case that need only slightly exceed in thickness the length of the lens-mount, the baseboard forming the whole or part of one side of the case, and automatically drawing out from the case to a fixed position the front or lens-carrier when the camera is being opened, and reversing such motion when the camera is

being closed. In addition, the camera can be so made as to enable the lens-carrier to be adjusted in an infinite number of positions either in or out of the perpendicular with regard to the baseboard.

The lens carrier is held between two uprights, which are each actuated by a pair of crossed arms or levers pivoted together at the centre, and also pivoted to the top and bottom respectively of the uprights, the other ends of the arms or levers being pivoted or connected to the camera case. The movement of the lower ends of the uprights is moderated and regulated by causing the pivot connecting the lower ends of the uprights to the corresponding ends of the corresponding arms or levers to move in a guide-way or slot of appropriate shape formed in a front base which is fixed to the baseboard of the camera.

By moderating and adjusting the lengths of the arms or levers, the positions and methods of pivoting and attachment, and the shape and size of the guide-way or slot, the objects above enumerated are attained. The thirteen figures of the specification are required for the explanation of the constructional details. Bertram George Cooper, 36, Clarence Street, Kingston-on-Thames.

**DOUBLET LENSES.**—No. 29,446, 1906. The invention is an improvement in certain of the Zeiss double objectives described in the Patent of Rudolph, No. 6,028, 1890. It relates to that kind of objective, each of the two components of which consists of a collective lens and a dispersive lens, both lenses being cemented together in the one component by a dispersive cemented surface presenting its concavity towards the diaphragm, in the other component by a collective cemented surface presenting its convexity towards the diaphragm, while in both components, or only in that one with the dispersive cemented surface, the dispersive lens has higher relative dispersion than the collective lens.

This improvement consists in that the collective lens, which appertains to the dispersive cemented surface, is produced from a glass of relatively high refractive index—that is to say, that the refractive index should amount to at least 1.54, consequently the height of the index should at least be that of a light flint glass. In all former constructions after the above specification, a glass of very low refractive index has been made use of for this collective lens, in order to obtain an especially large difference between the refractive indices at the dispersive cemented surface. Investigations, upon which the present invention is based, have, however, shown that the important point for the correction is not so much this difference, but rather the height of the index of the collective lens.

The advantage of the new objective consists in that relatively large apertures or small zones of spherical aberration or satisfactory flatness of field, can be obtained. This effect of the present improvement is independent as to whether the component possessing the collective cemented surface is composed of two or of three lenses. Carl Zeiss, Carl Zeiss Strasse, Jena, Germany.

**TRIPLET LENSES.**—No. 29,447, 1906. The invention relates to triplet photographic lenses with a diaphragm in front, in which a dispersive cemented surface presents the concavity, and a collective cemented surface the convexity towards the diaphragm. Such lenses are already known through the Patent Specifications, Nos. 23,378, 1892, and 4,692, 1893. Whilst, however, in the objectives described in these patent specifications, as also in the objectives of this kind placed on the market, the kinds of glass are chosen so that the difference in index of refraction at the dispersive cemented surface has about the same amount as at the collective cemented surface, according to the present invention a more perfect correction of the spherical or the astigmatic deviation can be obtained by augmenting the difference between

the refractive indices at the collective cemented surface—at the cost of the difference at the dispersive cemented surface—so that the difference at the collective cemented surface will be at least twice as great as that at the dispersive one.

The result of this improvement may be directed to manifest itself either in a spherical correction for a relatively large aperture, or in diminished zones of spherical aberration, or in diminished astigmatic differences combined with satisfactory flatness of the image. This result extends not only to single objectives, in which the sine condition is fulfilled simultaneously with spherical correction, but also to systems in which little or no regard has been paid to the sine condition. In the first case good components for convertible objectives can be obtained; in the second, components of which two must be combined into a double objective in order to show a quite satisfactory correction. Carl Zeiss, Carl Zeiss Strasse, Jena, Germany.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Exposure in Enlargement.

The rule is (says Mr. F. H. Jeffree in "The Amateur Photographer," in writing of the exposure of enlargements by rule) gauge the intensity of the light falling on the negative by means of an actinometer, and calculate the exposure as in negative-taking (multiplying by a suitable subject number to represent the density of the negative) and then multiply the exposure so found by the square of the linear enlargement plus one. Thus, if we wished to enlarge a  $\frac{1}{4}$ -plate negative to 12 by 10 inches, or to speak more accurately, to enlarge a part 4 by 3 inches to 12 by 9 inches—i.e., linear enlargement of 3, we multiply the exposure as ordinarily found by  $(3 \times 1)^2 + 4 = 16$ . There remains the question of density or negative. An unstained negative of just sufficient density to give a plucky print on P.O.P. will be our standard, and in negative-taking would correspond to an ordinary landscape without dark objects in the foreground, or a subject number of 1. Such a negative will take about 60 times as long to produce the print spoken of below, as the paper in Watkins' exposure-meter does to attain standard density—i.e., one minute for every second. Having settled on the standard, any other negative may be compared with it by making a contact print of the two negatives at the same time, and noting the time each takes to produce a harmonious print—i.e., not the time to produce a print suitable for toning and fixing, in which as printed, the shadows are all blocked up; but that which looks right as printed and not fixed—a proof, in fact. Thus, if the standard negative took 10 minutes and that from which we wish to enlarge took 25, the density would be reckoned  $2\frac{1}{2}$ .

### Actinometry for Ferro-prussiate Printing.

I have, in the course of business (writes Mr. Josiah Martin in "Photography") to copy surveyors' plans on ferro-prussiate or blue paper. As there is considerable difficulty in determining the proper time for exposure, I make use of an actinometer, in which I place a strip of P.O.P. When this prints a certain number, I know there has been light enough for the blue print, and I take it out and develop it in a water bath. This plan has always proved successful when the sunshine has been clear and strong. But, unfortunately, it fails just where it is most needed—that is, upon a dull and cloudy day. Under these circumstances, the blue print will gain considerably on the P.O.P., and when we read the usual indication on the actinometer we find the blue print very much overdone. This seems to indicate a different ratio of sensitiveness in the two kinds of

ing papers, the ferro-prussiate being more sensitive in weak than the gelatino-chloride of silver in the P.O.P. This opens a new field for investigation.

## New Books.

**Lucas's Book of Receipts.** Rewritten by E. W. Lucas, F.I.C., F.C.S. Pp. 418, 7 x 5 in. London: J. and A. Churchill. 7s. 6d.

It is difficult to imagine a volume more concisely eloquent of man's needs, ills, and vanities than this closely printed formulary, compiler whereof has spared no pains to give comprehensiveness to his work. A hurried glance through his pages shows a first prescribing remedies for pink eye and wooden tongue, then the formulæ for aerated waters, and for the preparations by which a promising but, alas! disappointing "head" may be induced to these beverages. Nine recipes for sauce of the "Worcester" are a mere trifle among the recipes for condiments which precede the equally numerous prescriptions for rat poisons, coloured inks, freezing mixtures, hat revivers, stains for wood, luminous paints, marking ink, weed killers, battery solutions, cooling powders, cures, gargles, insect-bite remedies, cough mixtures, pick-me-ups, moustache fixatives (and varnishes), face powders, hair driers—in short, well-nigh everything that is or can be commanded for the care of man and the beautification of woman.

This really well-ordered compilation contains a selection of photographic prescriptions which is made up of some leading makers' formulae, with a few other recipes which are useful as far as they go, and are not by any means the best selection which could be made to occupy the twenty pages allotted to them. Yet to anyone who has read of the preparations which we have only briefly indicated above, "Book of Receipts" is a most useful and moderately priced book.

**Deutscher Photographen-Kalender, Part II., 1907.** Pp. 578.

Weimar: Offices of the "Deutsche Photographen Zeitung." 2s. This is an almanac and pocket-book, edited by Herr K. Schwier, of Weimar contemporary, appears in its twenty-sixth yearly issue with an increased number of pages, but with the arrangement of its contents unaltered. Just as we look to "Eder's Jahrbuch" for the systematic record of technical advances by Continental and other photographers, so "Schwier" is an indispensable reference book of personal and commercial information. We do not exaggerate its usefulness when we say that hardly an inquiry as to an article or process of Continental origin is addressed to us but what a moment's consultation of its pages enables us to answer the querist. If we are destroying an editorial reputation for omniscience, we are nevertheless only giving Herr Schwier his due, and we should not mind if our correspondents sought help at first hand from his well-arranged volume. As before, the first portion is devoted to a list of photographic societies in Germany and Austria, divided into professional and amateur—there are 25 of the former in Germany—accompanied in each instance by the names and addresses of members. Particulars follow of the bodies connected with the photographic trade and with photographic employees. There is a list of photographic societies outside Germany, and of seats of photographic instruction in Germany and Austria. A directory of photographic publications of the world concludes this portion of the volume. The second portion (yellow pages) contains an alphabetical list of firms in the German and Austrian photographic and photo-mechanical trades, and a classified list of photographic requisites, with the names in each case, of firms manufacturing or selling them. Lastly, this commercial directory is completed by an alphabetical list of towns with the names of photographic firms in them. The matters above enumerated are all included in Part II. of "Kalender." Part I. is devoted to technical matters, photographic formulæ, etc., and is sold separately at 1 mark.

**Heat Shadows.** By W. Jamieson, B.Sc. (Lon.), A.M.I.E.E. Thirty pages, 7in. by 4½in. London: Blackie and Son. 6d.

This little work describes a series of experiments on the conduction and radiation of heat, which can be very easily carried out by any physical student with but simple apparatus, such as pieces

of wire gauze, cloth, and the special sensitive paper which is prepared by the author. Particularly interesting are the lessons dealing with the absorptive powers of colours for solar heat and the fact that, as the author states, a print may be obtained on his paper from a negative merely by the radiant heat of the skin.

**"CAMERA WORK."**—The current issue of Mr. Stieglitz's quarterly, for which the name of magazine seems scarcely good enough, is, in many respects, as entertaining and charming as ever. Its plates comprise five photogravures by Mr. Craig Anran, after certain works of his own, that it has been our pleasure to draw attention to when they have been placed upon exhibition, and a sixth by Mr. Steichen, also famous, and entitled "Pastoral—Moonlight." Of Mr. Craig Anran's, our favourites are the majestic "Stirling Castle" and the portrait of Jane Burnet, a perfect realisation of the dignity and graciousness of old age. If we may be hypercritical we should suggest that this fine work would have been finer still if the differences of weight, texture, and quality that must have existed between the black bodice and the wall or background had not been so entirely lost sight of. The other plates are the portrait of Strang, as "The Etching Printer," "Portrait of Miss C.," and the freize-like "Ploughing Team." Needless to say, they are a selection of unusual strength and beauty. Mr. Steichen appears to have spared neither time nor pains to make his Pastoral the artistic success it is.

Of the letterpress, much is taken up with fiction—that is to say, novelettes. We have not read them. The rest, so far from being fiction, appears to be what is described mechanically as "dead true," as we are informed that "Coburn has enjoyed exceptional advantages. Not the least of these has been his mother." A well-written article by J. M. Bowles reveals the fact that the writer has tired of modern excellencies of pictorial photography, and is athirst for a nice, healthy shock from something ordinary, and not too utterly intense. We feel with him to some extent. M. Demachy follows him with an article wherein he perseveres with his strictures upon the straight print, and comes to a frank and fearless avowal that photography, of itself, is not art. This view is one much in the air just now. On this side of the Atlantic it has found expression in the last shilling "Burlington."

## New Materials.

**Celloido (collodio-chloride) Self-toning Paper.** Made by B. J. Edwards and Co., Castle Bar Works, Ealing, London, W.

In making a bid for the custom of users of sensitive papers Messrs. B. J. Edwards and Co. have been quick to come into the market with the all-popular self-toning paper, and at the same time with one which is free from the drawbacks which attach to a paper with a gelatine emulsion. The collodion self-toning paper which they have just introduced as "Celloido" is evidently a distinctive product, which, in our experience of it, should command a high degree of favour, not only in respect to the quality of the print and its tone, but for the additional reason that Messrs. Edwards have introduced, as postcards, a number of tinted varieties of the paper (blue, green, orange, and grey), enabling the user to obtain a range of effects which may at all times be of the greatest advantage to him, particularly in the handling of negatives of too great contrasts.

In regard to the manipulation of the paper, the greatest praise which can be accorded the makers is to state that the directions for the use of the sensitive material are conspicuous by their paucity. The prints are taken somewhat deeper than is usual in printing gelatine P.O.P. and placed without washing in a salt bath of two ounces to the pint for three or four minutes. They are then fixed for five minutes in 10 per cent. hypos solution, and, after an hour's washing, are blotted off and dried in the expeditious manner possible with collodion prints. Our own results with both the paper and the postcards has given us great satisfaction, and it is no exaggeration to describe "Celloido" as a notable addition to the self-toning papers which should immediately make friends for itself among those who are able to judge of the qualities of a print. The glossy brand is a paper eminently suited for commercial work of high surface, the matt has given us delicate effects which recommend its use for artistic portraiture, while there are yet two other brands, the

"rough white" and "rough cream," which we consider a particularly welcome innovation, and one to which photographers should most certainly accord a careful trial. The results possess a richness and depth which are equal to anything obtainable in printing-out papers, yet are produced by the simplest conceivable manipulation. Though the cost of the paper is higher than that of standard gelatine P.O.P., a photographer may well consider within himself whether the reduced expenditure for chemicals and labour does not render the adoption of a self-toning paper capable of giving him his results an actually economical proceeding.

Though giving most agreeable brown tones by the simple salt-hypo or hypo process, "Celloido" easily yields very fine black tones on treatment with a single platinum bath, and this latter process is one which can be advised as an extension of the paper's facilities.

The prices of the paper are based on 22 quarter-plate pieces for 1s., in all four varieties—viz., glossy, matt, rough white, and rough cream, and in connection with their appearance on the market we may call attention to Messrs. Edwards' very reasonable offer to send post free a shilling packet of any grade or size for half the price—that is, for sixpence. We would recommend our professional readers to take advantage of the offer by asking for a packet of the grade which best suits their work, or they may, if they so desire, obtain on the same terms an assortment of all four grades.

Wellington Carbon-Surface P.O.P. Made by Wellington and Ward, Elstree, Herts.

"Another good thing of Wellington's" the discriminating user of sensitive materials will anticipate when he sees the announcement of the Elstree firm's new introduction of a printing-out paper with "carbon surface," nor will he be disappointed in the latest addition to the Wellington P.O.P.s, which has the richness and semi-sheen of the carbon print prepared on the average single transfer paper. In its toning properties it is equal to its P.O.P. predecessors from the factory of Messrs. Wellington and Ward, and we have no need to search for a more sincere expression of approval.

**NEW MOUNTS.**—The Crown Manufactory, Rotherham, send us some specimens of three new introductions of theirs, the "Cosway," "Medallion Oval," and "Panel Slip-in." The first conveys the relief effect of the fashionable "Cosway," and is of the appropriate dark-brown colour. In 10 x 8 size and with printed inscription it is 10s. 6d. per 100 post free. The "Medallion," also in 10 x 8 size and with a neatly drawn design for cabinet size of print is 8s. per 100; whilst the "Panel" mount takes a 4½ x 2½ print, and costs 4s. 6d. per 100. All three are worth attention.

#### CATALOGUES AND TRADE NOTICES.

"THE BOOK OF FORMULÆ AND INSTRUCTIONS," issued by the Lumière Company, of Lyons, France, is now in its fourth edition, and forms a complete guide to the use of the plates, films, papers, and chemicals manufactured by that firm. The causes of the more general failures met with in working, together with their remedies, are fully and clearly described, and a careful perusal of the booklet should prove of great assistance to those photographers who use Messrs. Lumière's specialties.

MESSRS. ERDMANN AND SCHANZ, of 109, Bedford Hill, Balham, S.W., have issued an abridged catalogue of their fine art photographs, which include copies of paintings and statuary from many of the principal European art galleries, together with a collection of direct studies.

MR. J. LIZARS, of Glasgow, London, Edinburgh, Liverpool, Belfast, and Aberdeen, has just issued a new and up-to-date catalogue, which contains particulars of practically everything which the photographic worker could require. Whilst there have been many improvements in the existing models of "Challenge" cameras, an addition has been made to their number in the form of the "Challenge Fulvue" reflex camera, an instrument of novel construction and extreme simplicity. A new form of enlarging easel is an introduction which will appeal to workers in this branch of photography. A number of formulæ for use with the various makes of plates and papers, together with many useful practical hints, have been included in the book, which will be sent free on receipt of a penny stamp. Applications should be addressed to Mr. Lizars, at 101 and 107, Buchanan Street, Glasgow.

## New Apparatus, &c.

The "Royal Mail" Stamp Camera. Sold by W. Butcher and Son Camera House, Farringdon Avenue, London, E.C.

This piece of apparatus, as the drawing shows, is for the making of postage stamp portraits, fifteen of which it produces on a quarter plate. The camera is provided with a set of single lenses, the definition afforded by which over each field of 1 x ¾ inch is nevertheless

exceedingly good. The lenses are covered simultaneously by shutter, controlled by the screw on the top of the camera, and the exposure is conveniently made in this way. The camera may be used for landscapes as well as portraits, being held on the tripod top to dispose the long side of the plate, either horizontally or vertically, as may be desired. Bushes are provided for this purpose. The negative having been obtained, a mask is used to print the

fifteen pictures, each with a plain border, and a second printing from a border negative, which Messrs. Butcher supply to register with the mask, suffices to supply each portrait or view with an ornamental border. The device is easy to manipulate, and might be used also for the making of the stamp negatives from cabinet photographs, since the focal aperture of each lens gives the sufficient depth of focus to obtain a sharp copy. The price of the "Royal Mail," with one single slide and tripod screw, is £1 5s. Extra slides are 1s. 6d. each and border negatives 1s. each, with three masks. Messrs. Butcher also supply P.O.P. ready perforated.

S. B. BOLAS AND Co.—The partnership between Samuel Bolt Bolas and Richard Lander Warham, architectural photographer and collotype printers, 68, Oxford Street, London, under the style of S. B. Bolas and Co., has been dissolved by mutual consent and from February 23, 1907. Debts will be received and paid by S. B. Bolas, who continues.

THE "RAJAR" CAMERA, offered monthly by Messrs. Rajar, Ltd. of Moberley, Cheshire, for the best print on "Rajar" P.O.P., has been awarded to Mr. William Cheetham, of Malpas Street, Oldham, whose print was judged the best received during April. The paper on which the print was made was purchased from Mr. Charles Garbutt, side, Hilton Arcade, Oldham.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, MAY 11.

ackney Photographic Society. Outing to Rickmansworth.  
outh London Photographic Society. Outing to Eynsford and Shoreham.  
owes Park and District Photographic Society. Outing to High Beech, Epping Forest.

MONDAY, MAY 13.

avesend and District Photographic Society. "Retouching." The President.

TUESDAY, MAY 14.

oyal Photographic Society. Ordinary Meeting. "The Camera at Home." E. T. Holding.  
ackney Photographic Society. Exhibition of Novelties in Apparatus.  
ackney Photographic Society. "Wrinkles." Harold W. Lane.

WEDNESDAY, MAY 15.

orth Middlesex Photographic Society. "Carbon Printing." H. G. Seaborne.  
ntral Technical College Photographic Society. "The Platinotype Process."  
emonstrated. The Platinotype Company.  
erton Camera Club. "Retouching Negatives and Prints." E. W. Scott.  
bridge Wells Amateur Photographic Association. Photography Prize Slides.

THURSDAY, MAY 16.

orth London Photographic Society. "The Lens in Theory and Practice." C. H. Madden.  
ndsworth Photographic Society. Conversation and Suggestions Relating to Exhibition Work.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held May 7, the president, Mr. J. C. S. Mummery, in the chair. The fourth of the series of demonstrations of obsolete photographic processes was given by Mr. J. Watson, on "Dry Collodion and the Tannin Process." Mr. Watson said that the period of photography which followed on the heels of Scott Archer's wet collodion process was aptly described by Professor Meldola as the "grocery riot," in reference to the fact that domestic products in great number figured in the formulae of that day. The so-called "preservatives" of the dry collodion plate included coffee, tea, sugar, raisins, salt, resin, beer, liquorice, and honey, and in 1859 the editor of the "Photographic News" was found to be discouraging a reader from a use of too much sherry! As in the wet collodion process, a substitute was needed to prevent the collodion film from floating off the plate down the sink. Rubber, albumen, and gelatine were the three best substrata, the last-named being the one preferred by Major Russell for his tannin process. That process, which the lecturer then proceeded to demonstrate in its various stages, was the best of the methods adopted in the sixties and seventies for preparing a collodion plate, which could be kept for considerable time between exposure and development. The lecturer used Mawson's bromo-iodised collodion, which he sensitised in a silver nitrate bath containing 36 grains of pyro and a little acetic acid. This bath was saturated with silver iodide by the very convenient plan of adding a small dose of the iodine to it, shaking up well, and allowing the precipitated silver iodide to settle out.

After sensitising, the plate was washed for a short time in distilled water containing a little acetic acid, then with distilled water, and then the tannin solution applied several times in succession. The plate was then drained, dried, and put aside for use. The strength of the tannin solution might vary from 2 to 30 grains per ounce. A stronger solution gave a deeper colour of image. The developer might be a weak alkaline solution of pyro or an acid solution of ferrous sulphate. In the former case a thin image was obtained and was intensified with acid silver. In the latter case a deep silver nitrate added to the developer gave the necessary density. Mr. Watson carried through the operation of preparing a negative of positive transparency, and incidentally referred to other methods which were contemporaries of the tannin process.

After a short discussion, a hearty vote of thanks to the demonstrator, on the motion of the chairman, terminated the proceedings.

OUTH LONDON PHOTOGRAPHIC SOCIETY.—On Monday last Dr. Norman's lecture on three-colour photo-micrography was delivered to a member of the society, Dr. A. R. F. Evershed. The apparatus used by Dr. Norman was first described, and pictured on the screen. The work-table, to ensure freedom from vibration, which is so essential in this class of work, has the legs resting in wooden cups containing felt wads, the apparatus itself resting on indiarubber washers. The illuminant used is limelight

with a special form of blow-through jet: the lenses for low-power work being Zeiss Planars, and for high-power apochromatic objective down to one-sixteenth. The fullest details were given of Dr. Norman's method of work, which is done by the Sanger-Shepherd process, using dyed lantern plates.

After showing the effect produced by the various single stainings, the finished three-colour slides were shown, these being probably the finest specimens of technical work in this direction ever produced, and a monument of patient, painstaking labour. The register of the slides was so perfect that even with a magnification of x2,000, plus that given by the projection lantern, no overlapping could be detected by the audience. The slides shown included various histological specimens, including several of bacilli of various virulent diseases, natural history specimens, and what was most pleasing to the audience, a number of mineral specimens taken by polarised light and selenite screens, the beauty of colour in these being much appreciated.

At the conclusion of the lecture a hearty vote of thanks was accorded the author (Dr. Norman) and to Dr. Evershed for his able reading of the lecture and lucid explanations of various technical and pathological questions which arose out of the lecture.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held May 4, 1907, Mr. T. E. Freshwater in the chair. Mr. H. Stuart lectured upon and demonstrated gum-bichromate printing. He said he was not going to detail the history of gum work, the broad principle of it being now well known; at the same time nothing could be standardised, each worker being a law unto himself. He therefore intended to explain and show how he himself worked the process. With regard to the paper used, there were many kinds available, although, personally, he only used one, viz., the "O.W." brand. This was a good stout, well-sized paper, and he purchased it cut to a special size of 18 x 14 at 7s. 6d. for three quires. The gum was ordinary commercial gum arabic of good quality, in a 40 per cent. solution. As pigments he used Windsor and Newton's process black, liquid sepia, and also at times cake colours, ground in water. He greatly preferred these colours to the powdered ones, because they did not require so much preparation by grinding. In fact, the process black and liquid sepia only required the bottle shaking. For sensitising a saturated solution of potass bichromate could be used, but he thought it better to powder the bichromate and weigh it out into twenty-four grain packets, his formula reading for black:—Twenty-four grains potass bichromate, dissolve in 2 drs. hot water; 4oz. 40 per cent. gum solution; 1 drachm process black; mix well. This was sufficient for coating six sheets for 15 x 12 prints. The coating was done by the aid of a mop camel hair brush, the paper being fastened by the four corners to a drawing board, and the pigment solution put on with the brush first worked from end to end and afterwards across, and afterwards softened off by a hog-hair softener some 4in. or 5in. in width. He preferred this class of brush to the sable softener so often recommended, which was in his mind too soft to do the work properly; any stray hairs should be lifted off by the aid of a pair of forceps. A sheet of 15 x 12 paper being coated in 15 seconds, drying could be done by placing the coated paper upon the rack of a kitchener, and the paper should, if to be kept, be stored in a calcium tube. He had kept it in this manner for a month, but it certainly did not work so easily. The negative should be thin, and printing done by the aid of a meter. He used Wynne's. The thin negative was of great use when using the multiple printing, as it enabled one to obtain exact register by looking through it. The printing-frame was dispensed with, a drawing-board, with strips of wood at one end and side, taking its place. The end was provided with an additional strip fastened by the aid of turn-buttons. This held the paper firmly in place, and the negative was pressed home into the corner, a sheet of plate glass being quite sufficient to keep all in register. Development might be done either automatically or by spray. Any running of the image was due to under-exposure. He developed by aid of the spray upon sheets of zinc stood upon an easel. When multiple printing was to be done the first print should be allowed to dry upon the zinc (which stood on edge), otherwise the paper was apt to dry unevenly and cause trouble in registration. If hung up it stretched by its own weight. The bichromate could be discharged from the paper either by an alum bath, or by sunlight, which method he preferred, as it gave a soft mellow effect. The colour of a print could be altered by coating it with a solution of gum, colour and bichromate, and afterwards discharging the bichro-

mate by sunlight. Skies could be put in either by printing from another negative or by printing through plain glass, and rubbing in with the aid of brushes. To do this the Wynne's meter should be provided with a sheet of ground glass in addition to the opal, and the first row of figures faintly printed; lamp-posts could easily be moved, and walls turned into fields. Shadows could be added where needed by allowing the printed surface to become dry, and rubbing in the colour, afterwards fixing it by the aid of gum and bichromate. A pleasing colour was made by adding liquid sepia to the process black; the gum should, however, not be altered, but the sepia added to the formula as given. This, he said, was the process as he worked it. Mr. Stuart then proceeded to coat the paper, and also developed prints. Messrs. Teape, Ernest Human, Burgess and Brigginslaw, took part in the discussion, a vote of thanks proposed by Mr. Rapson, seconded by Mr. Teape, closing the proceedings.

**CROYDON CAMERA CLUB.**—Wednesday, the 1st inst., was devoted to "Odds and Ends," and a sufficiently varied fare was provided. Mr. W. H. Smith showed a vacuum-cleaner of his own design for removing dirt and dust from camera bellows and the like, and remarkably well it did its work. Mr. E. A. Salt exhibited Messrs. J. Lancaster's "Eureka" daylight loading slide for glass plates and films, a very ingenious appliance, simple to work, and, so far as could be judged reliable in action. Mr. J. M. Sellors showed a combined cover, and rebated base, the latter taking a developing dish for time development in darkness. The brightest of lights could be used in the room without fear of fogging the most sensitive plate. He also showed an extremely simple, portable, and effective sky-shade, a little idea of his own. A piece of brass is soldered to a tie-clip, forming an extension piece, and a hole bored at the free end. The tie-clip is bent over at right angles to the front of the camera, and held in position over the lens by a milled-head screw, which passes through the hole in the extension piece and rigidly secures it, and the tie-clip. A few pieces of thin black card of varying sizes can be easily carried by the operator, and adjusted over the lens in a second or two, and inclined at any suitable angle to meet requirements. Folding side-wings can be provided if necessary. Mr. H. P. C. Harpur spoke of many things, and in particular of the merits of Mr. Baskett's oily concoction for local reduction. Certainly in Mr. Harpur's dexterous hands a negative worked upon showed a decided change for the better, judging from the gaslight print pulled from it before and after reduction.

**CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.**—On May 1, Mr. Wm. Cullen gave a demonstration on "Emulsion Making" before a very interested audience. After a few opening remarks as to the theory of the emulsion, the lecturer proceeded to make an emulsion and coat a plate, although, of course, many points, such as the prolonged cooking, were omitted, and some substitutions had to be made in order to facilitate the demonstrating of the process. A solution of gelatine, in which silver nitrate was incorporated, was first made. The lecture room was then converted into a dark room, and the potassium bromide was slowly added to the gelatine, and the whole well shaken up, when a precipitate of silver bromide slowly separated out. This being completed, the solution was poured into alcohol, which caused the emulsion to set, and after removal the alcohol was squeezed out. As this was very much like rubber it had to be re-dissolved in a fresh supply of gelatine solution, when the emulsion thus obtained was ready for coating on glass plates. The plate was allowed to set for a few minutes and then exposed under a negative, when a very good positive was obtained. The demonstration was very much appreciated, as the difficulties that Mr. Cullen had to contend against were fully realised.

**THE IMPERIAL DRY PLATE CO., LTD.,** of Cricklewood, announce that their "Special-Sensitive" orthochrome plates, which have hitherto been sold at special prices, will in future be sold at popular prices as follows:— $3\frac{1}{2} \times 2\frac{1}{2}$ , 9d.;  $\frac{1}{4}$ -plate, 1s.;  $5 \times 4$ , 1s. 7d.;  $\frac{1}{2}$ -plate, 2s. 3d.;  $7 \times 5$ , 3s.; whole-plate, 4s. 3d.;  $10 \times 8$ , 7s. 3d.;  $12 \times 10$ , 10s. 6d., and all other sizes, in inches and centimetres, at proportionate prices.

"**THE SOUTH AFRICAN PHOTOGRAPHIC JOURNAL,**" the publication of Messrs. E. H. Oakley and Co., Camera House, Cape Town, has been enlarged and revised, and is now a very live and active organ of the photographic doings of the Colony. It is issued gratis.

## Commercial & Legal Intelligence.

**A FALMOUTH BANKRUPTCY.**—At the Truro Bankruptcy Court last week, Mr. William M. Harrison, formerly a photographer at Falmouth and other places, applied for his discharge from bankruptcy. It was reported that the estate had realised 15s. in the £ and was likely to produce more. His Honour Judge Grange granted immediate discharge on payment of £2.

**A POSTCARD DISPUTE.**—At the Clerkenwell County Court, last week, Messrs. S. Hildesheimer and Co., Ltd., of 96, Clerkenwell Road, sued W. A. Haynes, of 4, Polter Street, Bishop's Stortford for £15 1s. 2d., being the first quarterly instalment of a sum of £50 4s. 8d. for goods sold and delivered.

Plaintiffs' travellet called upon defendant in April of last year and it was then agreed that the plaintiffs should send a photographer down and take certain local views, print them on postcard and as panoramic cards to defendant's order, his name being printed on the cards, and he having the sole right of the sale of these cards in Bishop's Stortford. Defendant gave an order for 1,000 each of the postcards and the panoramic cards, and it was agreed that he should pay in four quarterly instalments.

Subsequently defendant wrote and asked permission to amend the order, and later he wrote that he wished to cancel the order altogether. Plaintiffs wrote several letters to defendant, but only got a reply to one, to the effect that defendant adhered to his letter cancelling the order. The cards were printed, but defendant refused to accept delivery.

His Honour (to defendant): You cannot cancel except by the agreement of both sides, though if you had really done so the could only have sued you for damages—loss of anticipated profit but now you are clearly liable. Judgment must be for the plaintiff for the first quarter's instalment, £15 1s. 2d., and costs. Counsel for the plaintiffs said his clients would be prepared to come to terms with defendant for the payment of the next quarter's instalment of £15 1s. 2d., to avoid a further action, provided that the judgment now given was satisfied within fourteen days.

**DIRECT SEPIA BROMIDES.**—The adjourned hearing of the action brought by W. F. Cooper against J. H. P. Gillard, a brief account of which appeared in our last issue, can now be reported in full. The plaintiff, who is a director of the Cooper Research Laboratories, Watford, applied for an injunction to restrain defendant from selling a secret photographic process which produces a direct sepia bromide.

Mr. Valentine Ball (instructed by Mr. Matthew Arnold) was for the plaintiff, and Mr. G. H. Mallinson (instructed by Messrs. Camp and Ellis) for the defendant.

William Frederick Paulett, assistant chemist in plaintiff's research laboratory; Walter Harold Nuttall, Fellow of the Institute of Chemistry, Mr. Cooper's principal chemical assistant; and Ernest Charles Morgan, of Morgan and Kidd, Richmond, joint patentee with defendant of "agar agar," were called to give evidence for the plaintiff.

For the defendant, Maurice Berger, manager of a firm of photographic manufacturers; Miss Ellen McQuire, sister-in-law of the defendant; and William John Wilson, managing director of the Paget Prize Plate Company, were called into the witness-box.

His Honour, in giving judgment, first referred to an objection taken by Mr. Mallinson that the case was out of his jurisdiction. He certainly must say he felt very grave doubt whether he had jurisdiction in the matter at all. He had come to the conclusion that the relationship between the parties was not that of master and servant. Defendant was a person who had some skill, and who professed to have a process which was of value. He was to experiment at the laboratory of Mr. Cooper upon the value of his process, and upon the various ways in which it could be perfected and made of commercial success. Mr. Cooper certainly did suggest a line of inquiry in the mornings, and during the day defendant carried out his experiments. A master had a right to dictate to his servant not only what he should do, but how he should do it, and he saw nothing of that in this case, although it was quite true that defendant was receiving remuneration at the rate of £3 per week for those experiments. The defendant's position was, he did not hesi-

to say, a preposterous one. He said: "I went to work there, and I was to preserve my own secret rigidly, although I unfortunately allowed the plaintiff to know the composition, which I regret very much. I took elaborate precautions. I took a dummy lock down there, and anything which I discovered was mine." That was defendant's contention. If that were so, it seemed that plaintiff was paying Mr. Gillard £3 a week, and allowing him to use the laboratory for the sole and entire advantage of himself. That seemed to him, as he had said, a preposterous contention.

What was the true relationship between the parties? One was in the position of having capital and the other was dependent upon that he earned. Both contributed their skill and experience—the one as a chemist and a scientific man, and the other as a person who had a practical knowledge of photography and the requirements of the photographic trade. The discovery was made, and it seemed to him that the only possible relationship between the parties was partnership with regard to this particular secret, which was of great value. Their position in law was that they were entitled to the secret jointly. Here was a discovery, the result of the exertions of two persons, and neither of them—unfortunately for the plaintiff—thought fit to stipulate what should be done in the event of their investigations being successful. There is no express undertaking that neither should make use of the knowledge they had gained without the consent of the other. It is a case in which both partners could take what steps they chose to utilise the secret.

It was impossible for him to grant an injunction, but he must say on the facts of the case that defendant had taken up an entirely justifiable attitude. He had, according to his own evidence, prevented the action of the plaintiff when he asked him to carry out an experiment, and when he was told, "This is our joint experiment," he said "If it is your experiment I won't do it; let one of our boys do it." That was the way in which, unfortunately, this dispute came about.

Then defendant had also done that which seemed to him also to not honourable—that was to say, he had gone in the first instance to the Paget Prize Plate Company, and endeavoured to dispose of the secret without divulging what his position was with the plaintiff in the position in which both of them were working, which gave Mr. Cooper the right to say he was interested in the results. Then, when the plaintiff was endeavouring, notwithstanding that, to bring about a settlement by means of an agreement, defendant objected to it, and said that inasmuch as his interest in the proposed company might be terminated very soon, it was not sufficient. Defendant had not satisfied him that he had made the discovery in 1905, which plaintiff said was made in his laboratory, nor had defendant insisted that he was solely at liberty to exploit Mr. Cooper's laboratory, receive £3 a week, and then dispose of any secrets he might gain. The defendant had very largely brought these proceedings on himself. Assuming that he had jurisdiction, of which he had grave doubt, he found that the relationship between the parties in this case was not that of master and servant, but of two persons who were jointly prosecuting experiments together; he did not find any obligation between them not to divulge the results of the experiments, and on those grounds he refused the injunction. Mr. Ball asked that no order should be made as to costs.

Mr. Mallinson pressed for costs to follow the judgment. His Honour refused to grant defendant costs, on the ground that Mr. Gillard had taken up an attitude throughout which seemed to him not to be justified.

**STRIPPING FILMS FROM GLASS.**—The following formula was given by Mr. Longworth Cooper in a recent paper before the Manchester Amateur Photographic Society:—

Soak the negative for 10 minutes in	
Concentrated solution of caustic soda.....	7 parts.
Formalin .....	4 parts.
Water .....	200 parts.
then place without washing in	
Dilute hydrochloric acid .....	1 oz.
Water .....	20 oz.

Wipe the film at the edges with the fingers until it leaves the glass. If it be a film from a broken negative, wash the film and replace (under water) upon a sheet of glass a size larger than the original, and let it out and allow to dry.

## News and Notes.

**A MIDLAND PHOTOGRAPHIC FEDERATION.**—Mr. Lewis Lloyd, the hon. secretary of the Birmingham Photographic Society, informs us of the step being taken by himself to bind the Midland societies into one federation. A circular letter has been addressed to all known societies in the district, and Mr. Lloyd asks their consideration of his scheme. He also begs that any society which may have been overlooked will apply to him at The Hollies, Church Road, Moseley, Birmingham, for a copy of the letter, the text of which we may reproduce in explanation of the objects of the proposed federation:—"DEAR SIR,—It has occurred to me that considerable benefit would result to the photographic societies in the Midland counties if they were formed into a federation or union. In the districts covered by the four unions which already exist a great deal of good has been done in extending a knowledge of photography and in mutually benefiting the members of all societies composing them. Nearly all societies have joined, which is a proof of their usefulness. The chief objects are: Intercourse and exchange of opinion between the members of one society and another; united action for the purpose of discussing any question of importance to photographers, such as questions of principle relative to railway charges, etc., privileges for working in places of interest not open to the general public, etc.; interchange of prints and lantern slides; interchange of lecturers and lectures; special railway fares; the provision of a staff of judges, available for exhibitions and competitions. In the Midland district there are about 30 societies at present more or less isolated, but which, under this scheme, would become mutually helpful. From these societies a very strong lecture list could be drawn up, and the difficulties which a secretary often experiences in arranging the programme much lessened. I should be glad if you would do your best to secure the support of your society. Correspondence I shall gladly welcome, and hope that you will write me, giving your views on the matter. Later on I hope to call a meeting of delegates to draw up rules and a working constitution.—I am, dear sir, faithfully yours, LEWIS LLOYD."

**THE CHEMISTS' EXHIBITION.**—An immense variety of chemists' goods is collected in the Royal Horticultural Hall this week at an exhibition organised by our contemporary "The British and Colonial Druggist." The great firms which supply the chemist with the innumerable proprietary articles which form a large proportion of his sales have come, not in ones or twos, but in battalions, and the result is a scene of splendour which resembles the second act of a Seymour Hicks musical comedy, so profusely are colour and ornament showered on the stalls. Picking our way through this fairy land we came to where Mr. Hesketh, of the Thornton-Pickard Co., was seated amid the handsome "specialties" of that firm. Not far off was Mr. J. E. Lockyer, presiding over the display of ready-made developers, one form of which he now supplies at as little as 2d. The Rotary Photographic Co. made a strong show of bromide enlargements and colour prints, and, by the time these lines appear—it had not arrived at the Press view—of the new carbon-bromide process, by which the manipulation and sensitiveness of bromide are applied to produce a carbon print direct. In other words, the pigment is combined with the bromide coating, and is fixed by the operation of development. More will soon be heard of this new development of a comparatively ancient process. Messrs. John Sanger and Co. show the Walls Grove packet developers; and the Express Developing Co., of Whitechapel, a collection of enlargements which might have been more carefully selected, to say the least.

**ROYAL INSTITUTION.**—The annual meeting of the members of the Royal Institution was held on May 1, the Duke of Northumberland, K.G., president, in the chair. The annual report of the Committee of Visitors for the year 1906, testifying to the continued prosperity and efficient management of the institution, was read and adopted, and the report on the Davy-Faraday Research Laboratory of the Royal Institution, which accompanied it, was also read. Thirty-six new members were elected in 1906, and sixty-three lectures and nineteen evening discourses were delivered. The books and pamphlets presented amounted to about 216 volumes, making with 782 volumes (including periodicals bound) purchased by the managers, a total of 998 volumes added to the library in the year. Thanks

were voted to the president, treasurer, and the hon. secretary, to the Committees of Managers and Visitors, and to the professors, for their valuable services to the institution during the past year. The chairman announced that the managers had awarded the Actonian Prize of 100 guineas to Madame Curie, as the author of the Essay "Recherches sur les Substances Radio-actives."

**VALUE OF ADVERTISING.**—How business profits vary according to the amount spent on advertising was shown by plaintiff's counsel in an action for damages for alleged wrongful dismissal brought in the King's Bench before Mr. Justice Grantham and a special jury by Mr. Thomas Samuel Stevens against Messrs. B. F. Brown and Co., an American firm of boot polish manufacturers. Counsel stated that the advertising of the firm had been cut down, and the business commenced to fall off. He illustrated this by the following figures:—

#### ADVERTISING PROFITS.

	Spent on Advs.	Profits.
1880 .....	£130 .....	£264
1881 .....	£244 .....	£904
1882 .....	£654 .....	£1,683
1900 .....	£180 .....	£560

In this connection also we may quote Mr. Charles W. Post, chairman of the Postum Cereal Company, Limited, of Battle Creek, Michigan, U.S.A., and of Grape Nuts, Limited, in London, who has been speaking about the power of advertising at a dinner of the American Advertising Men's Club. He said that many years ago the newspaper advertiser was looked upon by the public with a certain amount of incredulity. But things were altered nowadays. A salesman who could talk winningly to a dozen customers was worthy of credit; but the salesman who could talk winningly to hundreds of thousands of customers through the newspapers could earn pounds while the other was earning pennies. His firm had spent £200,000 annually in newspaper advertising. Had it not been for the magnificent machinery of publicity supplied by publishers, his business, now worth from  $3\frac{1}{2}$  to 4 millions, would be a very small affair indeed. He could, therefore, never forget the debt he owed to newspapers. A good advertiser would talk to people in plain terms about what he had to supply, and by continuing such a policy would ultimately build up a reputation for his product. Two facts, however, stood out for emphasis. It paid to manufacture articles on strict lines of integrity, courting the investigation of skilled experts. Secondly, the unadvertised article, unknown to the people, might have merit, but it would not sell.

**THE PHOTOGRAPHIC RECORD AND SURVEY OF SURREY.**—The report for 1906 shows that good work has been done by the members, 371 photographs having been added to the collection during the year, making a total of 2,340, many of which have now become exceedingly valuable as being representations of things which no longer exist. At the annual meeting the Chairman stated that from the Secretary's report it was evident that the results of the year's work were most encouraging, and that the work of the survey was appreciated was demonstrated by the fact that during the year no fewer than 7,477 references had been made to the prints in the collection. The reports of the secretaries of the various sections were adopted, together with the financial statement, and the officers and Council for the ensuing year elected. The hon. general secretary is Mr. F. F. Wood, 11, Milton Road, Wallington, who will be pleased to hear from any interested in the work of the Association.

"THE EXPERT" is the title of a new illustrated weekly for collectors and connoisseurs which is announced to appear shortly; whilst possessing many of the characteristics of a magazine, it will be essentially a newspaper containing topical information interesting to the collecting public. The number of collectors is large and the objects collected varied, but the aim of "The Expert" is to include them all, and the preliminary details as to the scheme of the paper forecast its hearty reception by those for whom it is specially designed to cater. The price will be 3d. per week, or 15s. per annum, post free, and a presentation portfolio, containing four signed original lithographs by R. W. Macbeth, R.A., of pictures after Sir Joshua Reynolds, Romney, J. M. W. Turner, and Tintoretto is offered to early annual subscribers. Further particulars may be obtained on application to the Secretary, "The Expert," Ltd., 1, Albemarle Street, London, W.

## Correspondence.

- \* \* \* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.  
 \* \* \* We do not undertake responsibility for the opinions expressed by our correspondents.

### BLISTERS ON BROMIDES.

To the Editors.

Gentlemen,—With reference to the letter from Mr. C. Winthrop Somerville, in your last issue, the following cutting from the "English Mechanic," of January 12, 1906, is interesting.

This is a case of "Look on this picture and on that," for now he pipes a different tune.

"The second question is that of blisters. There are three principal chemical causes for blisters:—

- "1. The use of a caustic alkali in the developer.
- "2. Frequent changes into solutions and washing water of wide variations in temperature.
- "3. Very prolonged immersion.

"But there is a fourth cause, and to it fully 98 per cent. of the cases are due—the paper itself. The preparation of the paper for the adequate prevention of blisters is a comparatively expensive matter, and some manufacturers do not consider it worth while.

"I believe I have tested every make of paper in this country, and know of only one case where the manufacturers make satisfactory efforts to prevent blisters. I cannot, of course, give the name of the firm here; but in all cases where I have recommended it privately on this account it has given satisfaction."

I cordially agree with Mr. Somerville that it is "a pity that such a beautiful and comprehensive printing process should ever suffer from unjust criticism."—Yours faithfully,  
 SCRUTATOR.

### THE VARIATION OF TIME OF DEVELOPMENT WITH TEMPERATURE.

To the Editors.

Gentlemen,—We are all of us, I think, indebted to Mr. Ferguson and Dr. Sheppard for their replies on the above subject, which have cleared the air very much.

With regard to my calculated result of  $4\frac{1}{2}$  minutes, I did not find the correct temperature co-efficient for the developer, and I am much obliged to Mr. Ferguson for pointing out the error.

May I be so bold as to suggest that there are a great many photographers to whom logarithms are a sealed book, and who are therefore precluded from utilising such calculations, and that Mr. Ferguson would be doing very valuable service if he would put into plain words how such calculations could be done by ordinary arithmetic, and, if possible, the necessary formula for every developing agent.

I am aware that this would mean considerable work and necessitate the simple definition of K for each plate, but I think this might be done within reasonable limits, and it would be certainly very useful to those who really want to make sure of good negatives, and I think this would include the majority of workers, except possibly those who are followers of the advanced pictorial movement.—Yours faithfully,  
 PAUL M. CRANSTON.

### THE ETCHING OF THREE-COLOUR BLOCKS.

To the Editors.

Gentlemen,—I have been much interested in Mr. A. J. Newton's article in your last Colour Supplement, wherein he frankly avows that upon a certain test in three-colour work, "the proofs without any fine-etching were actually closer to the original than those that had had four days' work of skilful fine-etching upon them." I wonder whether you, gentlemen, or Mr. Newton, can call to mind an article I had the honour of writing for you last year, when I penned this passage: "Fine-etching is the confession of a theoretical breakdown. Moreover, in this country it is the bane of artistic work." I thought at the time I was right, and now Mr. Newton confirms me. Oh, if I only could have turned Mr. Newton on to a certain "Photo-Engraver" whose phials of his wrath had been upset by my article! "Photo-Etcher," indeed! Why he actually replied saying that Continental firms turn out satisfactory work because of "the longer time they can spend patiently fine-etching," and he

up racial characteristics and racial moral standards to prove wrong. Truly, "the whirlygig of time brings in his revenges." I sleep the sleep of the just to-night! My champion hath red! "Photo-Etcher" writhes in the dust!—Yours, etc.,

F. C. TILNEY.

## Answers to Correspondents.

Matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered less the names and addresses of the writers are given.

Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C.

For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. No unmounted copies of each photograph must be sent with the

ENLARGED NEGATIVES.—Will you kindly tell me why it is that my negative enlargements are so badly fogged? They are made by electric light applied from three carbons. I use a screen holding the transparency and tissue paper, as you will see sketch herein. Exposure about one minute,  $f/32$ , development very slow. (2) Are enlargements made by electric light as good those made by daylight?—F. H. K.

If, as appears to be the case, you have screened off all extraneous light, the cause of the fog would probably be in the developer, the plate, or both together. We suggest you try the addition of additional bromide to the developer, giving more exposure if necessary. (2) It depends on the character of the negative. If long, arc light is preferable; if soft, a more diffused light, such as daylight, is better. Many enlargers who do not use daylight still keep an oil enlarging lantern for flat negatives.

O.—The general conditions are about the same as here, and though wages are higher, so is the cost of living, and we doubt if you will be any better off. The best journal for an advertisement is "The Photographer," of 21 and 26, East Twenty-first Street, New York. Mr. Dundas Todd, of the Photo Beacon, Security Buildings, Chicago, might be able to advise you.

STON AND SONS.—We recommend "Retouching," by Arthur Tait, 1s. We do not supply books. We suggest you apply Messrs. Dawbarn and Ward, 6, Farringdon Avenue, E.C., who can execute your order.

USE OF NEGATIVE LENS.—In a telephotographic lens the focal length of the positive is easily measured, but it is difficult to find the focus of the negative. I have not succeeded with the perforated card ("Answers to Correspondents" column, Vol. 53, p. 1039). Will you kindly suggest another method? The negative is a single triple-cemented lens, about  $\frac{1}{8}$  in. thick. Which surface, concave or flat, is the focal length measured from?—W. S.

The probable source of failure is that the distances between age and object were too short; they must obviously be not less than four times the focus of lens. Another simple plan is

to cut a one inch by quarter inch slit in an opaque card, place in front of a candle or lamp, place the lens two feet from card, and behind the lens place a white paper, and shift the latter till a sharp image is obtained; then measure the distance from lens to card and divide the distance from object by this, and the result will be focus. The following method was given by the late T. R. Dallmeyer for finding with accuracy the focus of the negative combination of a telephoto lens: Focus accurately the image of some well-defined object with any ordinary positive lens, and measure the size of the image. Place the negative lens a short distance within the convergent beam from the positive lens. Then accurately focus the image formed by the combined lens, and measure its size. Note the distance of the screen from any fixed point on the mounting of the negative lens; call this D. Note the magnification that has occurred to the image formed by the positive lens alone; call this M. Now move the negative lens a little nearer to the positive lens, keeping the latter in a fixed position, and focus accurately a second time upon the screen, and, as before, note the distance of the screen from the same fixed point on the mounting of the negative lens; call this D1. Note the magnification of the image now formed by the positive lens alone; call this M1. The focal length of the negative lens is  $(D1-D) \div (M1-M)$ . This method avoids any question as to the exact nodal point to measure the focus from, but practically the concave surface may be considered to be the point to measure from.

OVAL TRIMMING.—Will you inform me, through the medium of your valuable paper, the best and usual method of trimming enlargements in ovals and circles.—PHOTO.

The usual and most satisfactory method is to use a metal template of the required size and shape, and a pivoted wheel trimmer. Any of the large dealers can supply you.

CINEMATOGRAPH.—(1) Would you please to tell me what are the latest books, and the price, on the cinematograph? (2) Also, if there is any special paper published which deals with animated photography?—LANCASHIRE.

"Living Pictures," by H. V. Hopwood (2s. 6d.), and "Animated Photography," by Cecil M. Hepworth (1s.). (2) See p. 337 of the "B.J." last week, May 3.

TRANSPARENCY.—(1) Accompanying this you will find a transparency made contact by electric light. It is of a very hard green colour, and I would be greatly favoured if you could tell me the cause of the green stain? I can remove it by immersing in sulphuric acid after washing, but I do not know why my negatives and transparencies should take this colour. It is an Imperial ordinary plate, very slightly over-exposed and developed with a normal pyro-soda developer. Until recently I got none of this stain, but a nice pure black, and I cannot tell the reason. The transparencies are made for reproduction work, and give very hard results, and I think the transparency plates are even worse than using ordinary plates. When the negatives are first fixed they are not green, but turn so in washing. I am very anxious to get softer greyer results in the transparencies. (2) Is not a slow plate, as a rule, best for a transparency? (3) Would it be possible to make these contact transparencies by daylight? (4) Can you give me the name of a good standard book on developing and the making of dry plate negatives, and transparencies? Is "Burton" as good as any? I do not mind a decent price for a really good professional book.—DARK ROOM.

(1) The chief cause would appear to be deterioration of the developer. Pyro-soda, which has become stale, is particularly liable to give this greenish stain. Try a new stock solution, with, say, half as much again or double the quantity of sulphite. If you have been using the Imperial pyro-soda formula, we advise you simply to omit the sulphite solution from No. 2 and use a 10 per cent. sulphite solution instead of water in making up No. 1 from the stock solution. We should prefer to use a developer like metol-hydroquinone, or kachin if we required soft grey transparencies. Pyro-soda is not the best for the purpose. (2) That is our own experience. (3) Only by having some shutter device for the short exposures which would be necessary. (4) None better than the "Watkins Manual," and "Developers and Development," by G. E. Brown. There is none on the transparency work.

CARBON PICTURES ON IVORY.—Would you kindly let me know as to

the following? Instructions for transferring carbons (double transfer) on to ivory or ivoryine—CLARENCE.

First make the print on flexible support in the usual way and dry. Soak one ounce of Nelson's No. 1 gelatine in a pint of water till soft, and then dissolve by heat. Then add twelve grains of chrome alum in two ounces of hot water, stirring well the while. Immerse the print in the warm solution till soft, then introduce the ivory, bring the two in contact, and squeegee together. When dry, strip off the flexible support. The ivory should be well cleaned with soap and water, to remove any trace of grease, before the print is transferred to it.

ALAN CRAIG.—It is against our rule to recommend individual goods.

There are a great number which answer to our description. Why do you not get a list, such as Fallowfield's (146, Charing Cross Road, W.C.)? As regards lens, we should advise an anastigmat of f/6 aperture by one of the leading makers.

W. WASHAM.—A very weak Farmer's reducer, best applied with a tuft of cotton-wool. In the case of very harsh negatives we should not consider this treatment necessary.

D. STUDIO.—If the whole of the end (No. 2) was of glass, and given a good slope, it would be an advantage, as you would then get a somewhat nearer approach to a side light. As you do not state the dimensions of the building, we cannot advise you further.

SWELLED GELATINE PROCESS.—(1) Can you tell me if there are any working details published of the swelled gelatine process? I have your last two annuals containing outlines of the process. The chief difficulty is in getting a film  $\frac{1}{4}$  in. thick to dry with a level surface for printing. Usually the surface is convex, higher at edges.—WM. J. B. BLAKE.

(1) Nothing much in the way of details has been published of late years on the subject, as the swelled gelatine practically has become an obsolete process. However, very full details of it, by Mr. Thos. Bolas, were published in our volume for 1879, p. 428. If the glass is quite flat and placed perfectly level there should be no difficulty in getting an even surface, although you appear to require an unusually thick film. (2) We know of no work specially devoted to the subject. (3) We cannot say.

L. TURGILL.—1. Out of business. 2. Osborne and Co., Red Lion Square, W.C.

BAS RELIEF.—We advise you to print from a positive transparency by the method given on p. 304 of our issue of April 19.

W. H.—1. It appears harmless. 2. We can see nothing of the kind. 3. Not in our province. Apply to a comic contemporary. 4. Any printer could get the matter up with suitable display. Try St. George's Press, Brentford; or Hood and Co., St. Bride Works, Middlesbrough. 5. You can copyright it as a literary work.

STUDIO.—If the sun is troublesome, ground glass is preferable. Instead of either, we should prefer to have two or three light wooden frames, covered with thin tracing linen, to slide along the roof to stop out the sun when necessary. Then you would be able to get an unobscured light in dull weather. For the blinds almost any colour will do, but dark blue or a light green are perhaps the best, as they yield a light that is comfortable to sitters. For the material, serge is as good as anything. So far as the photograph shows it, we should say that you have an unnecessary amount of glass towards the ridge of the studio—a foot or two less would suffice. A French grey colour would be less glaring to the eyes of sitters than the bright varnished wood.

BOOKS.—The only books we can recommend are "The Pose in Portraiture" (No. 1 of "The Photo-Miniature" Series, 6d.); "Light in Photographic Studios," by P. C. Duchochois (1s.); and "Artistic Lighting," by Jas. Inglis (2s. 6d.).

S. DHUNJEEBOY AND Co.—(1) The artistic has some slight aberration left (either chromatic or spherical), with the result that the definition is not perfectly sharp, or, rather, is a mixture of sharp and unsharp. (2) The making of the negatives is the same for all three. As regards printing, we should say the carbon film (Rotary) process comes nearest to your requirements. (3) The most certain plan is to make separate transparencies of the negatives, and, after registering them in position, to make a new negative by copying. Except for simple work, such as clouds and skies, combining on the enlarging easel is out of the question. We can

best refer you to "Enlargements: Their Production and Finishing," by C. Rodwell Smith (1s.). It is published by Hazell, Watson and Viney, Ltd.

INFRINGEMENT.—We should first, through your solicitor, ask the patentee what he proposes doing in the matter, pointing out to him the clear proof of infringement. If he refuses to make any offer, you should be guided by your solicitor as to what you should do. COLOUR PATENTS, ETC.—(1) Would you tell me the date of the patent of the process you describe in this week's journal as the Du Hauron one-plate process of colour photography, described as a screen consisting of a fatty matter and water dyes? Also in what country the first patent was taken out? (2) Would you please also tell me whether I can obtain material for Dr. Traube's colour diachrome process, also mentioned in this week's journal at the end of an article headed "The Bleach-Out Process"? Would you also tell me what date of THE BRITISH JOURNAL OF PHOTOGRAPHY would give me particulars of Mr. Ives' patent stereoscope, done by lined screen?—F. W. DONISTHORPE.

(1) Reference should be made to the "Colour Supplement" February 1, 1907, p. 14, where a review of one-plate colour processes is given. We believe that A. Baumgartner (English Patent No. 22,158, 1895) was the first to use the idea of fatty and aqueous dyes. (2) Perutz and Co., plate makers, Munich, are to be consulted as to Dr. Traube's process on the market; but, so far, no advertisements have appeared in the German press as to the actual introduction of the materials. (3) Particulars of Mr. Ives' patent stereoscope will be found on p. 8, "B.J.," January 1, 1904.

PRISMATIC PROCESS.—Would you kindly answer the following questions: (1) (reference, page 849, "B.J.A.," 1907) Is the ruled screen referred to in line 6 in a single-line or cross-line screen? (2) Is a grating of 500 lines per mm. superposed on the five-line screen, should it be placed so as to cross the lines of the latter, or parallel with them?—E. Y. E. N.

(1) The screen is a single-line screen. For fuller details of what similar processes see "Colour Supplement," "B.J.," January 1, 1907, p. 5; March 1, p. 18; April 5, p. 32, in "Patent Chronology"; and May 3, p. 38. (2) No. The grating must be absolutely parallel with the screen lines, so that clear space in the latter may act like the slit of a spectrograph, which, in fact, the arrangement practically becomes.

BABY SHOW.—I have started a baby show, which will run for months—May, June, and July—and the four babies who have the best photographs I am awarding money prizes. You advise me as to whom I can employ as judge, and what will be charged? If the entries do not exceed 100 I shall gain nothing or lose even if every customer purchases one photograph each at 7s. 6d. per dozen. Will it be wise to them to purchasing not less than one dozen at the said price? I might mention that the cause of so little profit on our hundred photographs is that the cost of advertising and of absorbing all the net profit.—BABY SHOW.

We suggest that you obtain a local personage—lady or gentleman—to judge the photographs, and either one would not do it without fee. Or, why not place an advertisement in your show in your local paper and beg the editor to act as announcing him as such, coupling his name with that of the paper on all the circulars you issue.

\* \* NOTICE TO ADVERTISERS.—Blocks and copy are received by the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the text portion of the paper.

## The British Journal of Photography

The Oldest Photographic Journal in the World.

## SUMMARY.

—The exhibition by members of the National Photo-Record Association will be closed on Monday next (Whit). It will be open at the usual hours until May 29.

hibition of reflex cameras and of photographs illustrating will be opened at the house of the "B.J." on June 13.

hibition of M. Demachy's oil prints is to be held at the next month. (P. 377.)

J. Wall commences on page 365 a series of articles on modern progress in orthochromatic sensitising.

'Professional Photographers' Association reports satisfactory results for the insurance of employees under the new Act.

raw attention to some notes on the selection and use of accessories which the professional photographer may well at the commencement of the summer season. (P. 363.)

teresting case involving the question of wages or notice ced in "Commercial and Legal Intelligence." (P. 376.)

s of two enlargement canvassers have been made in Scot-land at Wimbledon a canvasser was summoned for the unlaw-ation of a photograph. (P. 370.)

cho of the humour of collecting accounts comes from (P. 371.)

T. Holding at the R.P.S. on Tuesday discoursed on some means employed in his photography of figure studies

ey and useful application of platinotype and ferro-prussiate papers was recently shown to the Croydon Camera Club W. H. Smith. (P. 371.)

Robert James Wallace, of the Yerkes Observatory, has out a system of daylight sensitometry for photographic he first details of which appear on page 368.

## EX CATHEDRA.

### An Exhibition of Reflex Cameras.

We have to announce that an exhibition of reflex cameras at present on the market and of photographs illustrating the capabilities of reflex cameras will be opened at the house of the BRITISH JOURNAL on June 13. The following makers of reflex cameras have already signified their intention of exhibiting instruments of their design, which will be in the charge of an experienced attendant engaged by the BRITISH JOURNAL to explain their movements to visitors:—

Adams and Co.  
City Sale and Exchange.  
J. H. Dallmeyer, Ltd.  
Kodak, Ltd.  
J. Lizars.  
Marion and Co., Ltd.  
Newman and Guardia, Ltd.

Ross, Ltd.  
Sanders and Crowhurst.  
A. E. Staley and Co.  
Talbot and Eamer.  
Voigtlander and Sohn.  
W. Watson and Sons.  
Charles Zimmermann and Co.

The examples of reflex camera work will, it is anticipated, be representative of the facilities provided by cameras of this type and of the skill of well-known users. We desire at the same time to invite the co-operation of any into whose hands our letter of invitation may not have come. Within the limits of the available space we are anxious to hang meritorious work submitted to us, and for the information of our friends who intend to support the exhibition in this way we would say that prints should be mounted but unframed, and should reach us not later than June 5, to allow time for the preparation of a catalogue.

### The P.P.A. Handbook.

The seventh "Handbook" of the Professional Photographers' Association, issued to the members during the past few days, has been commendably revised and amplified in the portions which deal with the legal and commercial matters which are of importance to the photographer. Rights and liabilities in respect to copyright are here explained in a few notes, which, though short, yet convey the facts clearly and incisively. Insurance matters in relation to the recent Workmen's Compensation Act are discussed, and the satisfactory announcement made that by arrangement with one of the insurance companies members of the P.P.A. may insure their staffs on a scale based on the total wages paid annually. These and other items in the "Handbook" show the energy and discretion with which the committee have conducted the affairs of the Association, and the steps which they have taken to advantage every photographer joining its ranks. The benefits of membership are now too obvious for us to dilate upon them: those who may wish to consider them at leisure are advised to address the Hon. Secretary, at 89, Albany Street, London, W.

### Pinhole Photography of the Sun.

Writing in the current issue of "Knowledge," Mr. C. Ainsworth Mitchell narrates his experience in solar photography with a pinhole, in which application of the stenopaic method in photography he has taken a hint from the use of the pinhole as a screen for the eye when looking at the sun. The absence of strong light in a camera provided with a pinhole instead of a lens is doubtless responsible for the absence of veil from parts of the plate on which the image of the solar body does not fall, and so Mr. Ainsworth gets several exposures on a different part of a single plate. The most suitable diameter of pinhole is about 1-50th of an inch, at which aperture an exposure of 1-25th of a second (plates not stated) was sufficient for the unveiled sun. A simple form of long box pinhole camera might be used as a useful exercise in making photographs of the sun of fair size, though the definition cannot equal that of a telescope.

\* \* \*

### Full-Size Focussing.

Not long ago we referred to an American patent taken out for a camera in which a focal plane shutter with a white-faced blind was used. The image was focussed on the front of the blind and was viewed in a mirror fixed in the lower part of the camera at an angle to the blind, but out of the line of rays from the lens. The release mechanism of the camera brings the plate-holder forward the necessary distance before the exposure takes place. If we may judge from a recent advertisement in an American contemporary, a camera of this type has been placed upon the market by the Hales Camera Company, of Ridgewood, New Jersey, by whom it is advanced for high speed focal-plane work. The construction should permit of the employment of wide-angle lenses and in this respect may compare favourably with a reflex camera of the ascending mirror type. An examination of it should be interesting to any who have returned still unsatisfied from the now well-explained fields of camera construction.

\* \* \*

### The Arithmetic of a Convention.

Mr. Pirie Macdonald, just retired (with honours) from the Presidency of the Professional Photographers' Society of New York, has been giving an account of the stewardship, which he also took upon himself, to our contemporary "The Photographer," which has at last induced him to contribute regularly to its pages, only on the "terms" that he writes gratuitously. In the current issue Mr. Macdonald tells how, in organising the recent convention of the P.P.S. of New York, he set his face against the customary attraction of junkets, fêting, and pretty girls, and would have none of the revenue to be obtained from trade exhibitors. His budget, put in a nutshell, is as follows (we translate approximately into British money):—

	s.	d.		s.	d.
Subscription .....	12	6	Dinner .....	4	0½
			Employment Bureau less than .....		3½
			Certificate of Membership .....		9
			Prize for the best practical idea .....		3
			Studio demonstrations, single-picture exhibition advertising .....		8
Balance .....	4	1			5

Surely, concludes Mr. Macdonald, we do consider this a good record, and when it is beaten we want to know about it, quick—for it will prove that some one knows more about the business than we do, and we want to get in line. But, remember, it must be a better meeting, for less money expended.

### Distortion in Photographic Lenses.

Dr. Wandersleb, of Jena, has recently published a pamphlet\* on this subject and in it has given a most valuable résumé of the theory, and a review of previous works in which the matter has been discussed. He also gives a series of charts showing the amount of aberration present in each of sixty-four different types of lenses for varying distances of the object. In these charts the distances are expressed by the magnification, and he uses the symbol  $N$  for the reciprocal of the magnification, when  $N=1$  object and image are equidistant from the lens, while when  $N=\infty$  the object is at an infinite distance. The following is a summary of his conclusions, and we draw special attention to the fact that, though these conclusions may seem to be at variance with popular and popular text-books, they are, nevertheless, quite in accord with modern theoretical optics. He points out that distortion depends on the spherical aberration of the rays as well as on the so-called "tangent condition," consequently, the constructor can only correct for a definite value of  $N$ . For other values of  $N$  distortion remains, and, in general, it varies with the relative aperture. He then makes a special point of the following: "It is especially emphasised that, contrary to popular opinion, distortion is not, as a matter of course, absent in symmetrical objectives in the practically most important case of distant objects; when, however, it is corrected, the result is that the sharpness is [adversely] affected to an increasing degree with the size of the relative aperture. This adverse condition does not necessarily hold good in unsymmetrical objectives. The charts show that in the case of distant objects the majority of the rapid rectilinear exhibit notable departures from orthoscopia, while a few of the unsymmetrical lenses show very complete orthoscopia."

\* \* \*

### The Conditions of Orthoscopia.

Reference to the charts shows that the conditions appear to be rather remarkable in relation to the rule laid down with regard to rapid symmetricals, but, theoretically, this rule appears to be a sound one. We touched on this matter in an article on "The Correction of Lenses and the Petzval Condition," published on March 22. If a lens is to be free from distortion and also capable of giving a critically sharp image, then it must be free from spherical aberration both at the pupils and at the image foci. In other words, to say, it must be corrected for two different pairs of conjugate points at the same time. According to Seidel this can only be done by infringing the Fraunhofer or sine condition, or second Von Seidel condition, and must be fulfilled to eliminate coma, hence focus varies in the attempt to correct distortion. In the particular case of a symmetrical objective employed to on a scale of full size, all the ray paths are symmetrical and if the pupils are not spherically corrected the one is counteracted by that at the other, so that the image is orthoscopic. All such objectives are, therefore, naturally free from distortion when  $N=1$  and the aberrations referred to above only occur when the attempt is made to render the objective distortion free for great distances of the object, the most difficult case being  $N=\infty$ .

\* \* \*

### Aperture and Distortion.

It should not be forgotten that aperture affects the questions, and that the aberrations are greatest with apertures of  $f/4$  and over. The charts show some excellent results given by symmetrical lenses of apertures a little under

\* "Über die Verzeichnungsfehler Photographischer Objektive." By Dr. Wandersleb. 1907.

While some remarkable diagrams illustrate the effect of wide-angle lenses. It is interesting to see that N's "Panoramic" lens, at  $f/18$ , was actually free from distortion for distances from  $N=1$  up to  $N=\infty$ . At the distance this is run very close by Harrison's "Globe" at  $f/25$ , by Busch's "Pantosop," at  $f/30$ , Steinheil's angle "Aplanat," at  $f/16$ , and the Goerz "Hypergon," at  $f/11$ . The much abused wide-angle lens is thus remarkable in its drawing. Whatever faults it may have in drawing is not one of them, and the so-called distortion that it is supposed to produce is the fault of the not of the lens.

\* \* \*

**Barrel Distortion.**

The charts show that the distortion given by symmetrical lenses is almost invariably of the cushion variety. In non-symmetrical doublets the distortion for  $N=\infty$  is really of the cushion form, and when it is nearly correct the distortion for the nearer distances is of the barrel variety. In some cases the lens shows only the barrel type, but, as a general rule, it appears that the type of distortion varies from barrel to cushion as the focal length of the object increases. Frequently the type varies with the angle of view, the centre of the field showing one type and the margin the other. The amount of distortion is very slight in the great majority of cases, but, for a few instances, it has alarming proportions. These are mostly well-known lenses, and the chart therefore gives valuable information with regard to the reliability of these lenses for certain purposes.

## OUTDOOR ACCESSORIES.

Indispensable items in the photographer's equipment are more difficult to write about than those designed for interior use, for, in the nature of things, open-air scenes and scenic backgrounds used in the studio are necessarily indoor lighting, are bound to smack somewhat of the artificial. At the same time, very beautiful results are obtained with outdoor surroundings, and so the accessories look really natural, the results pleasing to one's clients. Indeed, an elaborate arrangement of accessories, representing a scene in an old or something of that sort, will more probably please than the more restrained and true pictures which other artistic photographers prefer. Of course, many famous painters used outdoor scenes as backgrounds, pictures of which the lighting was palpably that of the outdoors, and they are referred to as great artists; but it is still advisable for photographers to avoid as far as possible, consistently with gaining a livelihood, the criticisms of those who are always ready to sneer at the work of the professional photographer. Many good results can be made with no accessory but the background. A few leaves or flowers thrown on the foreground, here and there, and occasionally, or when needed, the sitter can be made to look more natural—add reality. If the background and foreground are not in one piece, some foliage may be used to advantage to break the line where they meet. A good stone pedestal, time-worn and stained, comes next useful; this accessory is a favourite with the artist. If you can arrange some flowers growing at its base the effect is good. It is a good plan to have some on arum lilies and one or two small rose trees, and with a small spike which may be placed in the foreground where required. A grass mat is useful for hiding the feet, if one may use the term. The old balustrade, out of fashion, probably as much because of its appearance as anything else, though it certainly has been

shamefully treated. Stone steps are favourite articles nowadays, and they tend to produce good poses. Some very elaborate set-pieces can be made with good step pedestals and outdoor furniture, but all must be really good imitations, and, except for their location in the studio, indistinguishable from the genuine article. The steps may very easily be designed to fold up, even if the full length of the background, or each step may be made complete in itself, so that one can be laid over the other. These do not take so much room as might be expected, for the average imitation step is too high for studio work. Four inches from tread to tread will be found ample. Imitation creepers add greatly to the realism of these pieces.

A sundial has always been a favourite object for introduction into outdoor scenes. Though occasionally beautiful, it is extremely unserviceable. The same may be said of elaborate gateways and imitation water, though a child's gate and fence, made easily with a saw, hatchet, and some nails, is well worth the making.

Some of the theatrical property makers could supply some excellent objects for our use. Should the reader frequent the theatre, he will continually covet some property and wish it were in his gallery. The introduction of a tree trunk—properly made, of course, and not a flat cardboard one—often goes well with a suitable background. The branch of a tree, not necessarily showing the trunk, if fixed a few feet in front of the background, and of the same description as those depicted in the latter, make the scene much less artificial. The bough must be an extremely good imitation, however, and the same must be said of anything else that is introduced to suggest reality. If one must use artificial grounds they should be made to appear as natural as possible by the introduction in a more prominent position than that which they occupy of something which looks perfectly genuine, so that the mind having said "This is true," will be more inclined to believe in the obviously sham.

Garden seats or furniture, unlike furniture for indoor use, should not be bought as if intended for its natural use, for the real thing would look too new and fresh when photographed. The commercial accessories are in this case better than they; indeed, everything connected with the representation of outdoor scenes is much more satisfactorily catered for by the trade than are indoor ones. Do not purchase too elaborate seats; a simple one painted to imitate the decorations of Father Time is all that is necessary. A wooden garden seat—all wood, of course, and not iron and wood—is a welcome change from the more usual stone ones. These may be made by the local carpenter or purchased from a garden sundries' establishment. After all this talk of imitations, it is a relief to advise that a plentiful supply of real flowers be at hand when possible. They brighten up the gallery and freshen things up generally as nothing else can.

We have up to the present forgotten the seascape in our anxiety about the landscape, but it is scarcely necessary to say that imitation leaves, however, profusely used, will not heighten the realism of the seashore. A few pebbles should be used instead, with a rock or two, either real or imitation if one shirks work. An old piece of fishing-net, a crab-pot or corks are good additions. We may have also some wooden sand-pies and a small sand castle for occasional use. There are many pitfalls in the way of accessories, and the photographer must be careful to see that nothing incongruous mars his effects, though he is scarcely likely to make such idiotic blunders as were common in the early days of photography. One example we recently found amongst the first of the negatives of an old studio constitutes a record. The sitter, in evening dress, is represented as standing in front of an open

landscape, church spire in distance, the foreground being a loud-patterned carpet, upon which was built a large, solid stone wall and pedestal, and growing over it, with roots in the carpet, was a piece of ivy. Hanging from the sky and carefully drawn over the ragged stone pedestal was a curtain. After giving this true example of what to avoid, we might once again refer the reader to the study of Academy pictures. He will be surprised to note, if he has not before done so, how frequently the artists introduce accessories. They are properly subdued, of course, and fall naturally into their place in the composition, but the fact remains that the best educated men in art

have not by any means discarded the accessory, as have many photographers.

After all, the dismissal of the accessory from a photograph is but a poor means of overcoming a difficulty, we wilfully do without that which might be of great advantage and pictorial value to us. It must be remembered, too, that the public upon whom we depend for our existence are not yet educated up to the art standard which the plain background attempts to set, but have a sneaking fondness for detail, brilliancy, and still no preference for simplicity and accentuation of the figure and the figure only.

## THE SINGLE PRINT AND THE BAKER'S DOZEN.

[The question of prices, ever with photographers, is reviewed in the following note from the current issue of "Wilson's Magazine," in the form of a suggestion that the "single print" system may be found of advantage, not only to leaders like Hollinger who have made reputations on it, but to every photographer who is aiming at distinction in the eyes of his public.]

We have never been able to understand the true inwardness of the number twelve. Why is it that we buy our rolls and eggs, pencils and portraits, by the dozen? Will the negative only give off a dozen prints, or has the sitter only a dozen friends and relatives?

Talking with a well-known Fifth Avenue photographer on the subject of the average portrait, he said: "I put into every portrait I make the best effort I am capable of; I have to, for all my work is sold on its merits—not by the dozen, but by the print."

What does this mean to the photographer and his patron? The photographer, not having had the word passed up from the receptionist that "the party wants a dozen 5 by 7 platins," proceeds to make the best possible negatives he can of his subject. His judgment will guide him in the matter of size and number of plates to expose. Several negatives of different sizes and poses are printed from, and the customer is invited to take as many as he wishes, or as few—the price for the first print from each negative being somewhat higher than that for reproductions.

Assuming that the portraits are good, customers will invariably

take more if they know that they can order them in threes, or fours, just as they need them, gauging their inclination by the condition of their pocket-book.

Of course, this method could not be adopted with advantage for every gallery, but there are many galleries where a change from the dozen idea to the single print would result in much better work for much better pay. A more or less extension of this idea would very soon begin to elevate photography in public estimation. There is under present conditions a close relationship between the tintype "artist," who makes "ping-pongs" at twenty-five cents a dozen on the Bowery, and the Fifth Avenue "society photographer," who "for this month only" will make platinum cabinets for six dollars per dozen.

Portrait photography has for too long been bound and held down by a too narrow conventionalism, too much imitation and too little originality. The most successful men, artistically and financially, are the men who broke away from the old-fashioned and worn-out methods into new and original lines like Core, "the children's photographer"; Macdonald, "the only"; Hollinger, "the single print"; Pierce, "home portraits"; Falk, "celebrities"; to mention but a few of them.

## PHOTOGRAPHY OF THE INFRA-RED SOLAR SPECTRUM.

(A paper read before the Paris Academy of Sciences.)

DURING the year 1906,<sup>1</sup> whilst experimenting with the method<sup>2</sup> employed, practically, first by Waterhouse in 1875, I noticed that the action of the infra-red rays was superficial. This observation led me to employ plates strongly dyed with a colouring matter which absorbed the actinic rays. I recommended chrysoidine and erythrosine as giving good results.

Since then, in the course of experiments with other dyes, I have obtained very much better results with malachite green, and I have been able to prepare plates the sensitiveness of which to the extreme red and infra-red rays is about ten times that of the ordinary commercial plates treated according to Waterhouse's method.

The plates are prepared as follows:—

Extra-rapid gelatino-bromide plates<sup>3</sup> are placed for about 10

<sup>1</sup> Comptes Rendus, June 18 and July 9, 1906.

<sup>2</sup> This method, based on the previously ascertained fact of the reverse action of infra-red rays on exposed plates, consists in fogging an ordinary photographic plate and exposing it to the solar spectrum.

<sup>3</sup> I used the  $\Sigma$  plate of Lumière.

minutes in distilled water containing a few drops of acetic acid. They are then immersed for the same time in an alcohol-saturated solution of malachite green, and are then rinsed quickly and dried. These operations are performed in the dark.

The plates thus prepared are exposed for 30 seconds at 75 c.m. from an electric lamp of four candle-power and then exposed in the spectrograph. If the preliminary exposure is done with the plates behind a violet screen (with exposure of three to five minutes at 30 c.m. from the lamp), the plates are still more sensitive.

As a result prints have been obtained of the solar spectrum from  $0\mu 750$  to  $0\mu 950$  in which one Angström unit has a length of about 1-10 of a millimetre, also photographs obtained of the A. band in the third-order spectrum, which show that the structure of this band is identical with that of the B. band.

The ray Z, which I described in my note of July 9, 1906, a short band degraded towards the infra-red, is resolved into

in the photographs made with the spectrum of the second order. These results were obtained with the Mont Blanc spectrograph, consisting of a collimator and a photographic camera, provided with achromatic lenses of 30 c.m. diameter and 60 c.m. length, and with a Rowland flat grating. This apparatus, only one at my disposal, obviously does not supply the most favorable conditions for the study of the infra-red spectrum. Nevertheless, with the plates above described, when the atmospheric conditions were good, an exposure of ten minutes sufficed in the region A and thirty minutes for the extreme region, and a second-order spectrum as photographed. Results also made with a spectrograph of weak dispersion (a carbon bisulphide prism) show that the reverse action produced by the

solar spectrum, on the malachite green plates previously exposed, extends to about  $\lambda$  6,000, to the extremity of the infra-red not absorbed by the optical parts of the instrument. The exposure necessary with this spectrograph was only thirty seconds.<sup>4</sup>

The highly red-sensitive panchromatic plate of Wratten and Wainwright, which have given the band B with an exposure one-fifth or one-sixth that permitted by the plates above described, allow of A being obtained only with a rather greater exposure, and are not sensitive in the infra-red beyond this ray.

G. MILLOCHAU.

<sup>4</sup> The sensitiveness of these plates has suggested to me that it might be possible to use them for monochromatic photographs of the sun in the extreme red, and even for the first portions of the infra-red spectrum, if a convenient spectroheliograph be available. This justifies the sentence in my note of February 18 last, criticised by M. Deslandres in a note of March 11, 1907.

## A REVIEW OF RECENT WORK IN COLOUR SENSITISING.

### I.

At the present time when the use of colour-sensitive plates has increased so much, it may not be out of place to give a brief summary of our knowledge of the action of "colour" or colour sensitisers, omitting as far as possible technical details.

The subject is an extremely difficult one, and complicated by many factors that one may well shrink from a systematic investigation, although such is much needed, notwithstanding the considerable amount of work which has already been done. Much of the work is too contracted, too limited in scope, and too remote from a definite plausible theory on the subject. It has been done with materials, both in the shape of emulsions of dyes, of practically unknown composition—that is, known to the experimenter. For a complete elucidation of the subject it would be essential, I think, for the experimenter to be first a dyer or dye chemist, secondly an emulsion maker, and thirdly a chemist. The last is, I think, the least important of the three.

#### Kieser's Experiments with Phthaline and other Dyes.

There is much literature on the subject particularly in Germany, which has attracted but little attention in England; of which, apparently, is in danger of being entirely overlooked or ignored, and some has apparently never been translated. To the latter class belongs a paper, "Beiträge zur Kenntnis der Optischen Sensibilisation von Silbersalzen," published in 1904, by Dr. Karl Kieser, a summary of which has not yet appeared in English. In order to render this paper accessible for English readers, the author's conclusions or results of his work is given. It may be advanced against the work that the investigation is restricted to but few and only two classes, and that the old adage, "Ex uno omnes," does not apply to colour-sensitizers. No one is ready to admit this than I am, but Dr. Kieser's work is characterised by two important features: first, he prepared silver halides himself, and secondly, purified the dyes at secondary bye-products and adulterants had no action. The first good feature may be, however, in my opinion, a negative one, because, as will be seen later, one must consider the dye as a sensitive salt, as used in dry plates at least, as a gelatinous salt and not as a pure halide. The reasons for this belief will appear later, although at first sight it may seem absurd to suggest that we obtain our images on gelatine. The two classes of dyes examined by Dr. Kieser were the phthaline derivatives, the negative ions of which combine

with silver ions to give almost insoluble silver salts, and the triamidotriphenylmethane dyes, of which no silver compounds are known, and which have, contrary to the phthaline derivatives, a strong basic character.

The silver salts employed were the chloride, bromide, iodide, and oxalate, and were used without any vehicle. Whilst it was desirable to examine the action of the dyes on the highly sensitive varieties of the halides, it was not possible to prepare these without gelatine, and, as Eder has pointed out, it is impossible to remove the last traces of this, by about 0.5 per cent., and this would complicate matters. The halides were precipitated from aqueous and alcoholic solutions, the former with the corresponding acids and the latter from pure salts. With all the halides both excess of silver and the halides were used, and the precipitates thoroughly washed.

The dyes were most carefully purified, in order that no bye or secondary products should complicate the results. Of the phthaline derivatives, fluorescein, tetrabromofluorescein (eosine), and tetraiodofluorescein (erythrosine), were used in the form of solutions of the anhydrous acids, the sodium and silver salts. The potassium salt of the methyl ether of tetrabromofluorescein (spirit soluble eosine) was also used.

Of the basic dyes, pararosaniline and hexamethylparosaniline (crystal violet) and triphenylparosaniline (diphenylamine blue, spirit soluble) were used.

It is impossible to give in detail the numerous experiments carried out by Dr. Kieser under all possible conditions, but merely his conclusions. The dyed silver salts were tested visually with the spectroscope for their absorptions, and also photographically for their bands of sensitiveness.

#### Separate Sensitising by Several Dyes.

One fact which the author discovers and patents is of importance. Hitherto it has been found that except in particular cases, mixtures of dyes are by no means satisfactory for colour sensitising, the action of one dye masking that of the other, and the resultant mixture being inferior to either alone. Dr. Kieser, however, finds that if the silver halides are dyed separately and then emulsified, the full sensitising power of each dye is obtained. The relative intensities of the individual regions of the spectrum behave in proportion to the percentage composition of the dyed halides, and to the absolute sensitising powers of the individual components of the emulsion. The chemical nature of the dyes is of no moment, and basic and acid dyes can be simultaneously used without interactions.

With the phthaline dyes there are two kinds of staining. The first consists in the formation of a compound of the dye and silver, and is as such subject to the laws of mass action, and therefore dependent on the solubility of the silver salt that is dyed, on the concentration of the dye solution, and the solubility of the silver dye compound formed. In accordance with this, the silver halides arrange themselves for this kind of staining in the order chloride, bromide, and iodide, which is the order of their capabilities of being stained; and the dyes are arranged according to their staining powers in the order tetraiodofluorescein, tetrabromofluorescein, and fluorescein. Analytically this method of staining could not be proved for silver iodide, for silver bromide only with tetraiodofluorescein, and for silver chloride also for tetrabromofluorescein.

This last result is what one would naturally expect, for it is well known that iodide will replace both bromide and chloride, and bromide replace chloride in the silver halides. The author does not point this out, but it is a well-known fact in emulsion making.

#### Methods of Dyeing.

The second kind of dyeing is independent of the solubility of the silver salt, etc., and the quantity of tetraiodofluorescein taken up by the silver halides is in the inverse order of the solubility of the halides. The quantity of the dye absorbed is therefore dependent on the negative constituent of the silver salt, but exclusively a function of size of the surface of the various modifications of a silver salt. This also applies to those varieties of the silver salts containing absorbed halides or silver nitrate, only in these cases the secondary action of the absorbed salts is frequently most prominent.

The quantity of dye taken up is within wide limits almost independent of the dye concentration; but this independence is connected with the character of the dye. It increases with the phthalines, it increases with the acid character, or, what is of equal importance, with the molecular weight of the anions. With tetraiodofluorescein it is completely constant below the possibility of the formation of a silver dye compound. The adherence of a dye to the silver salt grain during washing is dependent on this property of the dye. The fixed point, that is, the final degree of colouration after washing, is, however, with the same modifications, not independent of the original amount of colouration; as a rule, however, a final high degree of colour corresponds to an original high degree of staining.

With the basic dyes only the second kind of staining exists, and there is no essential difference to that of the acid dyes. As with the latter, the silver halides are arranged as regards the amount of dye absorbed in the order iodide, bromide, and chloride, and, as with the acid dyes, the amount of dye absorbed is, with the various modifications of the same salt, a function of the amount of surface. This fact explains why in the ordinary way the fine-grained washed collodion emulsion is more suitable for staining and optical sensitising than the coarse-grained gelatine emulsions. Even the strong giving up of the dye with pararosaniline is only a gradual, and not a principal, difference from the acid dyes, for the staining with tetrabromofluorescein, and still more with fluorescein, increases up to the fixed point much more strongly than with tetraiodofluorescein.

The rapidity of the staining is naturally to a great extent dependent on the concentration of the staining solution. With concentrations of about 1-1,000 mol. to the litre the principal quantity of the dye is taken up in a few minutes, and for greater dilutions measurements show that this is also the case within a few days. Qualitatively it appears as though the maximum of the intensity is attained more quickly with the basic dyes; measurements, however, prove that the reverse is the case.

The nature of the cation is, in the case of the acid dyes, without influence on the staining process; the only exception is the H ion, in the presence of which there is less intense or decreased rapidity in the attaining of the maximum staining. The silver dye salts are no exception, only formed with absorbed halide are more intensely coloured than other salts. Very finely divided or even colloidal silver salts are thus formed, which are both more ready for staining than the coarse-grained kinds. The more favourable action of the silver salts in the practice of sensitising should be due to a similar action.

With the triamidotriphenylmethane dyes no difference of action could be detected between the salts and the ammonium bases.

The shifting of the maxima of sensitiveness observed with many dyes in the dry state when compared with the wet state is certainly frequently explained by similar changes which occur with silver halides stained with aqueous hexamethylenepararosaniline on drying. Against the assumption that the absorbed dyes are in a hydrated form there is the fact that in the staining with an absolute alcohol solution of the dye there is a similar, though weaker, change of colour in drying. One must then assume a function of the alcohol as crystalline alcohol.

The staining from alcoholic solutions with both classes of dyes is very similar to that with aqueous solutions. With the acid dyes the first method of staining should be more difficult to observe, on account of the lower solubility of the silver halide in alcohol and the much higher solubility of the silver dye compound. As regards the second method of staining, that obtained with alcoholic solutions only differs from that with aqueous solutions in so far as the initial and final staining is slightly less.

#### Staining with Acid and Basic Dyes.

There is a remarkable coincidence of staining of the above mentioned acid and basic dyes from ethereal solutions of the dyes. Both, in opposition to the staining from dilute aqueous solutions, show an increase with the increase of solubility of the silver salts. Whilst for the basic dyes the cause of this behaviour was found in the existence of the dyes as undissociated carbinol bases in the solutions, no proof of reaction was found for the acid dyes, although the abnormal position of the absorption maximum was similar to that of dilute aqueous solutions.

There was considerable difference between the acid and basic dyes with respect to the action of additions to the solution. The alkaline halides, even with very low concentration, prevent the first kind of staining, which is due to the condition of equilibrium. As the ordinary gelatino-bromide emulsions always contain, and must contain, excess of alkaline bromide, it is obvious why the sensitising according to the first kind of staining has been so seldom observed. From the behaviour of the alkaline halides towards silver dye compounds Zettnow<sup>1</sup> had already concluded that the silver and dye salt could not sensitise as such.

#### Kiesers's Work on the Effect of the Silver Halides

The influence of the haloid salts can be deduced for sensitising of the second kind. But the similarity is only superficial. For instance, potassium chloride acts on the colouration of silver bromide much less than on the staining of silver chloride, and still less on that of silver iodide, whilst its action on the staining of the first kind can, on account of the increase of the concentration of the silver ions, increase in the reverse direction. Moreover, here the action of the halides is independent of the concentration of the halogen ions, which points to another kind of action. It appears very

1. "Phot. Korr.," 1889, p. 30.

le that there is some connection between the solvent of the additions for the silver salt that is stained and range of surface energy; but the existing tables of the solubilities of the silver halides in salts are insufficient to this point up, independently of the fact that they are drawn up for highly concentrated salt solutions.

h the basic dyes no action of the halogen salts could be proved, and that of potassium thiosulphate was reduced to a minimum, so that this fact is not opposed to the above-mentioned assumption.

It is clear that absorbed silver salts cause an increase of intensity of the staining with acid dyes in the ordinary way as it facilitates, even with dilute dye solutions, the action of silver dye compounds.

h the basic dyes the addition of silver nitrate differs little to the dye; whilst with pararosaniline it is very strong with the hexamethyl derivative it is very strong. This is in agreement with H. W. Vogel's statement<sup>2</sup> that methyl violet is a good sensitiser for gelatino-bromide and washed collodion emulsion, but is a very bad sensitiser for wet plates—s, for collodion plates rich in silver nitrate.

monia lowers the intensity of the staining with acid dyes, its efficacy probably lies in its solvent powers for the silver for it is greatest with chloride, less with bromide, and with iodide of silver. The favourable action of ammonia in chemical sensitising is ascribed by Eder to molecular changes in the silver bromide.<sup>3</sup>

2. Ber. Deutsch. chem. Ges., 1894. 1196.

3. Beiträge zur Photochemie und Spectralanalyse. Part III.

Sensitising is not connected with the staining of the vehicle.

Also with dyes which are generally sensitisers for silver salts the appearance of staining is no proof of sensitising. An example of this is to be found in silver iodide; as a rule this absorbs large quantities of dyes, and yet, in the absence of soluble silver salts, cannot be optically sensitised. An important function of the sensitising appears, therefore, to be the easy reduction of a silver salt by chemical developers.

As regards the non-sensitising action of triphenylrosaniline no explanation can be given; as regards staining, the dye behaves normally.

The following fact is not without interest: It is well known that coarse-grained, ripened silver chloride is vigorously sensitised by fluorescein. Now, the amount of dye taken by a gramme of silver chloride is only 0.03 milligrammes, and this amount is divided, with a size of grain of 2.5  $\mu$ , over a surface of not less than 40,000  $\text{cm}^2$ .

From microscopic examination it was proved that within the times of observation there was no marked penetration of the staining into the silver grain; it was entirely superficial, although the spectroscopic behaviour of the staining requires the assumption of a solution of the dye or its silver salt in the silver grain.

The assumption that the absorption stripe corresponding to the staining of dilute solutions of the eosines or the maximum of sensitising agrees with the maximum of absorption of the silver salt dye compounds must be considered as improbable.

E. J. WALL, F.R.P.S.

(To be continued.)

## WAYSIDE NOTES.

is a Russian, a M. Mastrukoff, now in this country, offering the particulars of a method he has discovered of applying dyes to photographs. The results are good, judging by the portraits of specimens shown, but how far they are due to M. Mastrukoff's artistic skill and how far to his process, only those who have used his information can tell. His plan is to sell exclusive rights to one studio in a town, but I rather think that he will find it more difficult to effect sales in England and Scotland than on the Continent. Among the letters of recommendation from Continental photographers that he carries is one from Gerschel, of Paris, addressed to "Dear Brother Strauss" in St. Louis, commending to the care of that gentleman. One imagines a festive evening under the protection of "the dear brother"!

\* \* \*

his critique of the exhibition now open at the New Gallery, C. Lewis Hind has a certain passage which is well worth citation by photographers. It runs: "A journeyman painter forges his style and technique and always employs the same method. Master looks at a sitter with a fresh eye, and lets the appearance of the sitter suggest the style and technique of the painting." I should like to hear Mr. Hind's opinion of some of the show-cases of the "masters" in photography.

\* \* \*

wonder how many readers of the "B.J." read the article in "Colour Photography," Supplement of May 3, written by Mr. William Gill. For myself, I must confess that, although I take very keen interest in colour photography, every word of Mr. Gill's article was like a breath of the bracing East Anglian air of old Roman town in which Mr. Gill has his studio. If any reader of this article I most heartily recommend him to hunt up his "B.J." and read it—not once, but over and over again. And having done so, it and noted the transparent sincerity of it, he shall say to himself that any profession of which a man can write in terms such as these is no mean one, and that any association of its members of which such a man is on the Council is well worth joining. Then, perhaps, he will feel inclined to measure up how far his work is

below that of Gill of Colchester, rather than how far it is superior to that of the "backyard" man of whom we have been hearing lately. And perhaps, also, he will think that he ought to send his five-shilling subscription to the P.P.A. Perhaps!

\* \* \*

Take any town you will in which there are half-a-dozen professional photographers, and ask each of them what is the state of business, and the chances are that every one of them will tell you that it is bad. Inquire further, and granted, of course, that you are on fairly intimate terms with them, ask to what do they attribute it, each will advance an explanation that to him seems all sufficient, but which, in reality, is incorrect. The proprietor of the old-established studio will very likely tell you that it was the introduction of the dry plate and ready sensitised papers that spoiled photography. He forgets that no small part of the profits of those early years was derived from the premiums he received from pupils and the low wages at which his apprentices worked. When those young people had acquired a fair knowledge would they not naturally set up in business for themselves? And in so doing, they would have increased competition whether photographic processes had been simplified or not.

\* \* \*

Another favourite argument is that the amateur has materially injured the professional. But close investigation convinces me that such is not the case. There are, of course, instances where it can be traced that definite losses of business can rightly be attributed to the amateur, but they are the exception rather than the rule. The amount thus lost is nothing compared with that which is gained by those professionals who have added a dealing department to their studios. I know a man in a Midland manufacturing town, the appearance of whose premises betokens him to be not only an artistic, but a successful photographer, who makes a big feature of amateur work. He even advertises in his local newspaper and gives his own long experience in photographic work as a reason why the amateur should come to him rather than to the chemist.

No. It is neither the dry-plate nor the amateur that makes each of those six photographers less prosperous than he would like to be. The real reason is that while the population has only increased by about one-third there are six studios, instead of one, to be supported by it. It must be admitted that more money has to be spent by the public on photographs to maintain six studios than would suffice to enable the proprietor of one to make the big profits to which the old-timers so regretfully refer.

\* \* \*

And it is not only in professional photography that the pinch of competition is keenly felt. Look at the brass plates of the doctors, the lawyers, the dentists, and remember that in their case they are debarred by professional etiquette from advertising, and that they can do nothing more than wait for their clients to come. Then there are the shopkeepers, grocers, chemists, and so on, confronted with the competition of the many-branched Liptons, Boots, etc., a competition that it is practically impossible to withstand. With company branches and shopping by post increasing all the time the average shopkeeper is face to face with keener competition than any photographer.

It is consoling to reflect that neither shopping-by-post nor the company can hurt the photographer. The latter has been tried but has not proved permanently successful. Too much depends on the personality of the man running a studio; once a manager that the success of his branch depends on himself and not on employers, he will very soon get into business for himself. I know studios under managers whose work has been quite satisfactory to the employer at a distance, and yet when those managers have come proprietors they have done far better than they ever did before.

\* \* \*

One expects anything that is sent out from Elstree to be good, and the Wellington Carbon Bromide well sustains the firm's reputation. Doubtless the Carbon P.O.P. will be equally good, but could not Messrs. Wellington and Ward have chosen better names? If I were a maker of carbon tissues I should feel that carbon work was being indirectly recommended, and it is quite certain sooner or later the dealers and trade printers will find the name lead to confusion. There is also the possibility that in a few instances the Carbon P.O.P. prints will be shown as genuine carbon in the same way as platinum-matt bromides have been dishonestly substituted for plantintypes.

THE MAN ON THE ROAST

## THE DAYLIGHT SENSITOMETRY OF PHOTOGRAPHIC PLATE AND A SUGGESTED STANDARD DISPERSION-PIECE.

[A paper in the "Astro-physical Journal."]

THE universal adaptation of the modern dry plate, and the varying demands which are made upon its service, have resulted in an increase of knowledge relative to the imperfections of the photographic plate as a means of recording anything save the actual form of the object photographed. In many cases even that is doubtful. These imperfections have compelled the "testing" of the various plates by many individuals, the object of such tests being principally the determination of the relative colour-sensitiveness and comparative speed.

Many methods have been suggested for this purpose, the enumeration of which need find no place here. It is sufficient to say that methods depending for their results upon the use of coloured glasses and pigments are now generally recognised as incomplete, and as leading to erroneous conclusions where the work is in any degree quantitative. What one desires to know is the sensitiveness of the plate to pure colour, not admixture, because, if one knows this sensitiveness, it is a comparatively easy matter to calculate the action of mixtures. For example, a patch of red-pigment-stained paper may be photographed, and a strong impression of the same developed upon a plate; but it does not follow that because such an impression is obtained the plate is "red-sensitive." For although the patch reflects red, it also, in less degree, reflects all other hues of the spectrum, and the developed impression is just as likely to be due to the combined action of such other hues as to the red, when we take into consideration the fact that the plate is relatively many times more sensitive to those hues which are secondary in reflection.

Discarding these various makeshifts, a great number of photographic workers have of late acquired various forms and types of spectroscopes, and have literally flooded the journals devoted to that subject with all sorts and conditions of spectra. This, while to be welcomed as a move in the right direction, is yet liable to give rise to many very grave errors in interpretation. The gravity of these errors has been commented upon by sundry writers at various times, and a brief notice was given to the subject by the present writer in a former paper.<sup>1</sup> It may, however, contribute to the clearness of this whole subject if such errors are described here at somewhat greater length.

The possession of a "spectroscope" does not imply results of value unless its possessor understands his instrument, and is acquainted with the laws of light and colour. Much excellent material is readily available, and there is little excuse for the heterogeneous results

which are unhappily so common in photography, in which almost every worker appears to be a law unto himself.

The three constants which govern the definition of colour are hue, purity, and luminosity. By "hue" is meant what is ordinarily termed "colour," for when we speak of an object as having such a colour, we are referring to its hue. The next constant, purity, concerns the admixture of the colour with other colours, or with white light; while luminosity refers to the brightness of the colour under consideration. Of these three constants the photographic plate is chiefly concerned with the last.

The entire value of the spectrum for this class of investigation work lies in the fact that in it we obtain a standard of pure colour from the verdict of which there is no appeal, and to which everything coloured must inevitably be referred. But there are many wide differences in the forms of spectroscopes available, from the small direct-vision prismatic instruments to the concave diffraction grating, each of which has its own particular value for different lines of work, but which are, generally speaking, ill suited for sensitometric work of pure photography.

### Prismatic and Diffraction Spectra.

First dividing the subject into its two great classes of prismatic and diffraction spectra, let us consider each separately. In the first instance, we are dealing with a spectrum formed by the passage of light through a prism (or prisms), as the name implies. In the direct-vision instrument, of which the Browning may be taken as a type, we have an element of dense flint glass combined with an element of crown glass. In instruments of angular deviation type, we have generally an element of flint glass alone, used on account of the greater dispersion obtainable from a glass of comparatively high refractive index. In all prismatic spectra the error arising from irrationality of the unequal distribution of intensity (luminosity) is not so apparent, however, although rendering the results by one prism not comparable with those from another. A very serious cause of error lies in the fact that the absorption of the glass composing the prism has a strong influence upon the results; generally speaking, the higher the refractive index of the glass employed, the greater the absorption. Again, two prisms of identical refractive index may give photographic results diametrically opposite to each other, because of varying absorption in the prisms themselves, aside from density; for example, two prisms could have identical refractive indices, and yet one be composed of colourless glass, while the other was composed of grey or blue glass.

<sup>1</sup> "Astro-physical Journal," 23, 153, 1906, and 24, 268, 1906.

### Conversion Formulæ.

Various formulæ have been advanced from time to time, designed to bring those discordant results into harmony with one another; unfortunately they do not satisfy the conditions demanded in sensitive plate-testing. They are all principally concerned with dispersion of the spectrum, and not with its relative luminosity. What one wants to know is, not merely whether or not a plate is sensitive to red, but in what degree that sensitiveness exists. All plates are sensitive to the least refrangible hues, if they get sufficient exposure, but that plate which requires relatively the shortest exposure,

when a wave-length scale being then prepared, this curve was reduced by means of the above formula, the result of which is shown in Fig. 3, *a*. On the same scale are plotted the measurements from a spectrum negative obtained by a replica-grating upon a similar plate, the value of whose region of highest density was practically identical with that of the reconstructed curve of the prismatic spectrum. The woeful lack of agreement is strongly in evidence. Not only is the reconstructed curve deficient in the ultra-violet, but the maximum of sensitiveness is seen to be shifted bodily toward the red end. Further words are unnecessary on this point. What is wanted is a formula

Diffraction (Fig. 1) and Prismatic (Fig. 1*a*) Daylight Spectrum on Cramer Trichromatic Plate.

Fig. 1.

Fig. 1*a*.

COMPARISON OF LIGHT-SOURCES USED IN SENSITOMETRY.

- |                            |                                 |                               |
|----------------------------|---------------------------------|-------------------------------|
| b. Candle Flame.           | e. Incandescent Electric Flame. | a. Acetylene Flame.           |
| c. Scheiner Benzine Flame. | d. Magnesium Flame.             | f. Cramer "Inst. Iso." Plate. |

Other things being equal, is the best plate for work in that line; or, in other words, that plate which will show the greatest amount of the spectrum with normal exposure is the best plate for all work.

The formula most commonly in use by photographic workers is  $m = \frac{a}{b}$ , where  $a$ =prismatic dispersion,  $b$ =normal dispersion,  $m$ =ratio of prismatic spectrum, and  $n$ =density of normal spectrum;  $am = bn$ .

In order that we may clearly understand the value of this formula, a measurement was made of the prismatic spectrum ( $\mu_D = 1.6994$ ) shown in Fig. 1*a* and its curve plotted in the usual manner (Fig. 2). A

which will take into consideration the loss in luminosity by absorption and the shift due to density of the material used in the construction of the prism.<sup>2</sup>

### Reflection Diffraction Grating.

Turning now to diffraction spectra, it is well known that the speculum metal on which the original grating is ruled possesses in itself a selective absorption which again varies with different "meltings," and which influences the distribution of colour-intensity throughout the spectrum. As the grating ages it becomes tarnished by exposure to the air and the various fumes of the laboratory, and

<sup>2</sup> A search for a formula fulfilling the requirements specified is now in progress with prospect of a successful result.

this tarnish is in itself a strong factor in unequal colour distribution. Again, the nature of the groove made by the cutting diamond not only determines the distribution of spectral intensity, but influences also the luminosity of the individual hue, amounting in exceptional cases even to abnormality, so that the spectra of no two gratings are definitely comparable one with the other, in so far as spectral luminosity is concerned.

### Replica-Grating.

It may be objected that several of the complaints just cited do not amount to much in practical photographic sensitometry. Granted that this is so, they are disadvantages, and have been treated as such. Not all have been mentioned, however, but merely those which can be remedied by the adoption of the replica-grating as a standard dispersion-piece for investigative work in sensitometry, when used without the addition of a prism.

Inasmuch as anything is a "standard" if we know what it is, we may begin first with the material of which the replica-grating is manufactured. We have a definite compound, collodion, resulting from the mixture of amyl acetate and pyroxylin, which is always prepared in the same way. The replicas themselves are composed

Fig. 2.

of the same amount of solution, dried under similar conditions, and give a film of the same thickness. These replicas are made from the same original, and are therefore practically identical, while the grating from which they are made gives a fairly even distribution of light throughout the various orders. These films are mounted upon glass of similar thickness, quality, absorption, and refractive index.

There is no possibility of surface oxidation of the replica, nor does selective absorption enter into the account<sup>3</sup> for all the methods necessary to a complete test of photographic plates.

Inasmuch as the distribution of intensity is greatly dependent upon the shape of the groove made by the cutting diamond, it may be argued that equally minute differences in the grooves of the replica-grating would have the same effect. While this is undoubtedly true, yet, as a matter of fact, such differences, although looked for, have not yet been detected. In a spectro-photometric examination of a number of replicas, all made from the same original, at different times throughout the course of five years, which had been prepared under temperatures varying about 8 deg. C., the results were gratifyingly exact. The method of manufacture, however, would indicate such results, when we consider that the shrinkage in the drying would be identical, provided the conditions and materials were similar. Obviously the same argument applies to the method of mounting.

While it is not claimed that the replica-grating is perfectly suited for all classes of work, yet it is believed that its adoption in sensitometry would avoid the great lack of accord between the results of one worker in photography and that of another, with the unprofitable discussion which inevitably ensues.

<sup>3</sup> "Astrophysical Journal," 22, 129, 1905.

After many experiments, and consultation with authoritative scientists, the writer offers this form of grating to the photographic investigator for adoption as a standard dispersion-piece in sensitometry, in the hope of establishing uniformity in photographic results. In order, furthermore, that this standard may be disseminated widely and be of universal application, the writer has decided to present to each known investigator in photography of any nation

Fig. 3.

ality, who may apply, one of these standard replicas of a size suited to his needs.

It may be argued that no replica-grating can be compared for defining power with an original ruling. Argument upon this point is unnecessary, inasmuch as what is wanted for photographic investigation is not critical definition of spectral lines, but the correct definition of spectral hues. In most of the negatives the Fraunhofer lines are purposely obliterated, because they interfere with the measurement. It is, however, now a matter of common knowledge that good-quality replica-gratings leave little, if anything, to be desired on the score of definition, and, except for the spectroscopy of position, even those of secondary quality define far in excess of the requirements of the work in hand.

ROBERT JAMES WALLACE

(To be continued.)

### CANVASSING FRAUDS.

During the month of April a large number of complaints were received by the Ayr police regarding a number of canvassers who were calling on respectable people in the town and representing that they belonged to the Scottish Art Company, 48, Shamrock Street, Glasgow, that that company was about to open a branch at Newmarket Street, Ayr, and that in order to advertise themselves they were giving away free 150 enlargements of photographs. The recipients were to be at no expense whatever, their only obligation being to hang the enlargements in a conspicuous place in their houses. In almost every instance the canvasser succeeded in getting a photograph to be enlarged. Usually about ten or twelve days later a second representative of the firm would call with an unfinished enlargement, but without the original photograph. After exhibiting to the persons in question samples of frames, he asked which one they would choose. He was invariably met with the answer that framing was not in the bargain, and that the first canvasser had distinctly told them that they would not be called upon to hang the enlargement framed by the company. In most instances the parties refused to have anything to do with the enlargements, and demanded back their original photographs. There, however, the company's representative had the whip hand, as he refused to return them the original back unless they stuck to what he called the bargain. The matter was taken up by Detective Inspector Craib, the Ayr Burgh Police, and he obtained a warrant for the arrest

members of the firm. He went to Glasgow on Friday last, accompanied by Detective Kirk, in possession of the warrant, with the result that one was arrested at 48, Shamrock Street, Glasgow. The other two, however, could not be found, but after a little inquiry they were traced to Edinburgh. The Edinburgh men were then brought into connection by telephone, with the result that it was learned that the firm had a branch office at 10, Street. About an hour later word was received that the first of the trio had been arrested. The third man has not yet been discovered. The final issue was that two of the three men in question appeared before Bailie Vincent at the Burgh Police Court on Tuesday, charged with formulating and carrying through a violent scheme, but their case was adjourned for a week, bail fixed at £5 each. For many years the public have been canvassed by these so-called Art Companies, and it is creditable to the police to be the first force to take the matter in hand.

The Wimbledon Police Court last week, Eliza Payne, Barnes Lane, summoned C. J. Sweetman, 7, Ridley Road, for unlawful detention of a photograph. Prosecutrix, a witness box, said that some weeks ago a young lady came to her place and asked for an order. She gave her a photograph of her eldest daughter, which was taken away for an enlargement, on condition that there was no order given, and that the photograph with a proof was to be returned in three days' time. About a week later Mr. Sweetman came to her shop and laid down a photograph in an elaborate frame. She told him she did not want one, and it was only a proof she desired with the photograph. Sweetman insisted upon the photograph being handed back to her at once, and defendant told her he would burn the photograph if she refused him. Defendant stated that he had called upon prosecutrix several times with the proof, and she would not look at it. A young man in the employment of Mr. Sweetman spoke to canvassing for her, and told her that unless the proof satisfied her she need not order a picture. The Bench ordered the photograph to be returned, and allowed 7s. 6d. costs.

#### REQUESTING SETTLEMENT OF OUR ACCOUNT."

A dull round of business must not be so dull in a country where there are people such as the writer of the following letter, received from an American professional photographer, Mr. C. L. Lewis, of Toledo, Ohio, and rescued from oblivion by our contemporary Son's Magazine." Mr. Lewis had applied for settlement of an account, and the line on his stationery, "Artistic Photographer," provoked the inscription of the witty letter.

Lewis, Toledo, Ohio.

"Artistic Photographer."

DEAR SIR,—Like a blessing and a benediction, or a breath of life from those enchanted isles where waving palms lifted their tops in air, and airs that breathe from Paradise upon a land of crime—and like many other things which I can't quote—your bill and annotation. I like the naïve originality of your bill and annotation. I like the naïve originality of some on red paper and some on blue (a most appropriate) and yellow and white, but be the colour scheme what it may, it is always that freshness, a new surprise, an exhilarating new-thing to one world-weary and sick of the sameness of things—a cooling draught of frappé wine to a man in Hades. Heaven bless us! (I cannot at this moment recall any other place from which they do not come, now.) They are the bright beacons that pierce the dark days and pierce the gloom of nights from month to month. Who would be without them? (Who on earth can be?) say, Blessings be upon the head of whoever it was that invented and triple garlands of blessings upon the head of him who discovered a method of paying them. What would life be without the busy Bill. One might be tempted (were this not ruled necessary) to write a roundelay to Bills:—

Bills in the morning,  
Bills in the evening,  
Bills in the afternoon,  
Same old tune—

Please pay soon, etc.

I am surprised beyond measure at your very sordid attitude towards the little Alice-blue slip with which you so kindly favoured me this week. Not at your sending the bill—ah no! I would not

have it otherwise—but at your memoranda concerning such things as rent (vulgar custom—rent), groceries (consider the lilies, they toil not, neither do they spin). Remember, you are an artist. Go to George Bernard Shaw and read "Man and Superman" and what he says—a great artist—says of the artist—(for fear you won't go, I'll give it to you)—and then be ashamed:—

"An artist, if he be a true artist, will starve himself; will allow his family to starve; will permit his old mother to work to support him and will see the wife of his bosom die of want, rather than that he will desert his art or do anything but his work."

Now, you know you're not a real artist. You're a sordid, mercenary machine. Instead of an artist you ought to be manufacturing Chromo-litholeo-Margarino crayon portraits "for the trade." But if you persist in shutting your eyes to the wonderful stars and your ears to the far peaks of song—all right, your blood be on your own head, and to further increase your damnation I'll send you \$100 (please pardon me for mentioning money in a letter) next Monday.

"Just for a handful of silver he left us,

Just for a ribbon to stick in his coat.

Found the one gift of which fortune bereft us.

Lost all the others, he left us devotion."

That's the way the late Mr. Browning sizes up your apostasy. Now aren't you sorry,—Yours very sorrowfully,

#### PHOTOGRAPHIC TILES.

WHEN the name of Mr. W. H. Smith is down for a lecture, or demonstration, whatever may be its nature, an interesting and invariably instructive evening is assured at the Croydon Camera Club. There he recently chose for his principal theme, "Photographic Tiles," not the ceramic variety necessitating firing and furnaces, but another sort excelling the real article in many respects, if not in indestructibility. Briefly, prints are made in any process not exceeding the regulation size of 6 inches square, and stuck down with glue to slabs of wood, or even stout cardboard of the same dimensions. They are then sized and varnished, and mounted up in much the same way as tiles in juxtaposition, or with slips in between. The best effects, perhaps, are obtained by making the picture 4 inches square, with a border of one inch. This may be left blank, or separately printed with a design cut from a paper stencil, or simply shaded, a graduated tint looking well. Such tiles can be made use of in the home in a variety of ways: for the decoration of overmantels, panels, and the like. A small table, or a tray, with a neat moulding added for the reception of the tiles—which for protection should be covered with a sheet of glass—would also be novel and attractive. In the case of panels, a tall flower like a lily might be photographed in sections, and would form a graceful and highly decorative subject. Generally speaking, the best subjects for the purpose would be of bold and simple design, and care must naturally be exercised to select them in harmonious relation to each other. In whatever way the idea is carried out it would, Mr. Smith said, serve to propitiate the feminine members of the household, too apt to sum up the science and practice of photography in one comprehensive word—viz., "mess." The truth of this remark evidently struck his hearers forcibly, for out of the large number of specimens passed round, very few returned to the lecture table, and many members must have left that evening with a tile loose somewhere.

#### BLUE PRINTS.

Blue prints are very effective and realistic. The formula suggested, the lecturer said, might be all wrong theoretically, but it worked, and certainly this was borne out by the extremely fine blue prints shown. [We can confirm this.—Eds. "B.J."] A hard-sized paper, such as Rive's or Steinbach's, is preferable, but if not obtainable, a 2 per cent. solution of Nelson's No. 1 photographic gelatine should be made up, and allowed to set. The jelly is placed in a small muslin bag and rubbed over the paper until it lies flat from absorption of moisture. With a very little practice a very even coating can be obtained in this way. Other sizing mediums, such as starch, might be substituted, and no doubt would work well. The sensitising formula is:—

Potassium ferricyanide ..... 10 per cent. solution.

Ferric ammonium citrate (green scales) 20 per cent. solution.

Take equal parts of each, allowing 3 cc. of solution for each square

foot of paper. The solution can be conveniently applied by means of a stout strip of celluloid covered with one layer of sateen, both being bent over into U form, the free ends being secured.

The sensitive paper, which will be found even more rapid than platinotype, should be printed until a full strength image is apparent, though its initial appearance lacks the brilliancy of the finished product. The print is then developed, and simultaneously fixed in a faintly acidulated bath of hydrochloric or acetic acid for a few minutes, rinsed, and dried. Hydrochloric acid tends to give a blue inclining to purple, acetic acid a purer tone. An alternative and tentative method may be adopted by first dipping the print in plain water, in which it will go back; immersion in an acid bath (about 1 in 100) will bring an access of vigour, which if too pronounced may be weakened by again transferring it to plain water, and so on.

#### JAPANESE TILES.

The "Japane" platinotype papers lend themselves readily for the purpose, and owing to their colour and quality they will, generally speaking, harmonise better with their surroundings. No sizing before varnishing is required, and should a semi-matt surface be preferred, the varnish can be omitted. Any accumulated dirt is easily removed from time to time, by rubbing over the surface with a clean moist rag. As illustrating what the paper will stand in this direction, Mr. Smith liberally smeared over a villainous-looking compound of soot and oil, and subsequently removed it without leaving a trace behind.

The evening concluded with a practical demonstration of minor workshop practice, and the manipulation of platinotype fabrics.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between April 23 and May 4:—

ETCHED SURFACES.—No. 10,047. Improvements in the art of producing etched surfaces, more particularly printing surfaces. Spencer Carleton, 7, Southampton Buildings, London.

CINEMATOGRAPHS.—No. 10,078. Improvements in cinematographs or the like for preventing accidents through fire. Emil Gottlieb Homes, 40, Chancery Lane, London.

IMPROVEMENTS.—No. 10,212. Improvements in or applicable to photographic productions. Sam Langier, 321, High Holborn, London.

CAMERAS.—No. 10,236. Improved photographic camera. Lodewyk Jan Rutgers Holst and Louis Borsum, 18, Southampton Buildings, London.

DARK ROOM.—No. 10,247. New or improved portable dark room for photographic purposes. Thomas James Griffiths, 88, Chancery Lane, London.

PRINTS.—No. 10,258. Improved process for converting photographic silver prints into coloured prints. Arthur Traube, 7, Southampton Buildings, London.

CAMERAS.—No. 10,269. Improvements in cameras or finders for cameras. The Thornton-Pickard Manufacturing Co., Ltd., and William Booth, 6, Bank Street, Manchester.

DAYLIGHT LOADING.—No. 10,359. Improved camera and daylight loading device. Samuel Henry Crocker, 37, Chancery Lane, London.

PRINTING LAMPS.—No. 10,358. Improvements in photographic-printing apparatus with mercurial lamps started by being tilted. Thomas Thomassen Sabroe, 65, Chancery Lane, London.

PLATES.—No. 10,400. Improvements relating to photographic plates. Edwin Ebenezer Burnett, 57, Chancery Lane, London.

#### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

ANASTIGMATS.—The invention relates to a lens in which the chromatic, spherical, and opaque astigmatic and other errors are corrected by a novel method. It consists in the combination of

two positive and three negative lenses, with air-spaces between each lens arranged in two combinations. One of the combinations consists of two meniscus lenses, the outer one being positive and the inner one negative. The other consists of three lenses, one of which is a positive meniscus, another of which is a concave negative lens, and the third of which is a meniscus negative lens. The two combinations are of greatly different focal power when used alone, and the perfect correction is obtained by using the two combinations together, each of five lenses being essential to perfect optical performance. The air-spaces between the lenses are of the shape of two negative meniscus lenses and of two positive lenses. The two meniscus-shaped air-spaces are nearest the outside of the lens, the two positive air-spaces are in the interior of the lens.

The three negative lenses are constructed of glasses, one of which has a greater refractive index and dispersion than the positive lenses, another has a smaller refractive index and greater dispersion than the positive lenses, whilst the third has a smaller refractive index and a lower or approximately the same dispersion as the positive lenses. The positive lenses ( $L_1$  and  $L_5$ ) are made of a barium crown with relatively high refractive index. The meniscus lens  $L_3$  used as the negative element of the combination which consists of a pair of lenses is constructed of a dense silicate flint glass, whilst in the combination which consists of three lenses the negative meniscus lens  $L_4$  is constructed of a light silicate flint, and the other negative lens  $L_2$  is constructed of a silicate crown.

By careful calculation of the curves and separations of the series of five lenses arranged in this manner an objective can be constructed which is unusually well corrected for the errors of central spherical and chromatic aberration, and at the same time is corrected for astigmatism and oblique spherical aberration for a very large angle of view. The invention permits of the construction of an objective of this type with lenses whose individual powers are all very low, the initial aberrations,

of which are comparatively small, and therefore the complete lens is not so sensitive to small variations in the thickness of the lenses and air-spaces as those in which individual lenses of high power are employed.

Fig. 1. is a drawing showing the optical portions of a lens.  $L_1$ ,  $L_2$ ,  $L_3$ ,  $L_4$ ,  $L_5$  represent the five lenses, the lens  $L_1$  being the nearest from the photographic plate,  $R_1$ ,  $R_2$ ,  $R_3$ ,  $R_4$ ,  $R_5$ ,  $R_6$ ,  $R_7$ ,  $R_8$ ,  $R_9$ ,  $R_{10}$  present the radii of curvature of the various surfaces. The central thicknesses of the five lenses are denoted by the letters  $d_1$ ,  $d_2$ ,  $d_3$ ,  $d_4$ ,  $d_5$  respectively. The axial thickness of the air-space between the lenses  $L_1$  and  $L_2$  is denoted by  $d_6$ , that between  $L_2$  and  $L_3$  by  $d_7$ , that between  $L_3$  and  $L_4$  by  $d_8$ , that between  $L_4$  and  $L_5$  by  $d_9$ . We append below the optical data for constructing a lens according to our invention, for

cal length being ten inches and the effective aperture about one-fifth of the focus.

Radius of Curvature in Inches.	Glass Constants.	Thicknesses of Lenses and Air Spaces in Inches.
$R_1 = + 2.19$	barium crown $\mu_d = 1.6065$ $\nu = 58.1$	$d_1 = .18$
$R_2 = + 7.4$		$d_2 = .236$
$R_3 = + 2.69$	dense silicate flint $\mu_d = 1.6193$ $\nu = 37.4$	$d_3 = .097$
$R_4 = + 1.62$		$d_4 = .569$
$R_5 = - 29.7$	silicate crown $\mu_d = 1.5193$ $\nu = 58.7$	$d_5 = .076$
$R_6 = + 35.3$		$d_6 = .118$
$R_7 = - 1.59$	light silicate flint $\mu_d = 1.5703$ $\nu = 41.1$	$d_7 = .139$
$R_8 = - 2.705$		$d_8 = .215$
$R_9 = - 7.4$	barium crown $\mu_d = 1.6065$ $\nu = 58.1$	$d_9 = .18$
$R_{10} = - 2.19$		

It will be evident that the curve  $R_8$  is capable of alteration to a flat surface or even a slightly convex curve by suitable modification of the refractive powers of the various glasses. In a similar manner  $R_2$  and  $R_9$  may be made either flat or slightly convex, and we do not limit ourselves to the above arrangement of the refractive indices; it is a well-known fact that the oblique spherical corrections of a lens are very rapidly affected by the shapes of the individual lenses, and in our present case the essential feature lies in the general shapes of the lenses combined with the dispersive ratios of the four most powerful lenses. Considerable variation in the refractive indices may be made, the necessary compensation being made by slight variations in the focal powers and separations of the individual lenses without departing from the general shape. As an instance of this—lens No. 2 may be made of glass with a refractive index of 1.64, and the compensating alteration in the curvature required will be that the curve  $R_3$  should equal 2.8 inch and the curve  $R_4$  should equal 1.64 inch combined with a slight alteration in the distance apart of the surface. As another instance, the refractive indices and curves of lenses Nos. 2 and 9 may be interchanged and the compensating corrections are made by altering the distances between the surfaces and altering the power of lens No. 3.

The claims are for:—1. A compound photographic lens, spherically, chromatically, and astigmatically corrected, consisting of two positive and three negative lenses all separated by air spaces, two of which air spaces are of the shape of a positive lens and two of which are of the shape of a negative lens, the two more powerful of the three negative lenses being meniscus-shaped and being made of a glass with greater dispersive power than that used in the positive lenses, the two positive lenses being either meniscus, plain convex, or double convex, the curvature of the surfaces facing the negative lenses in the last case being very slight.

2. A compound photographic lens spherically, chromatically, and astigmatically corrected, consisting of two positive and three negative lenses, all separated by air spaces, two of which air spaces are of the shape of a positive lens and two of which are of the shape of a negative lens, the lenses being arranged in combinations with a diaphragm between them—one combination consisting of a meniscus negative lens with a higher refractive index and a higher refractive index than the meniscus positive lens, the other combination consisting of two negative lenses, one at least of which is meniscus, both of which have a higher refractive index than the meniscus positive lens, and one of which has a higher dispersion, and the other approximately the same or a lower dispersion than the meniscus positive lens, substantially as described. Conrad Beck and Thorace Thorpe Beck, 68, Cornhill, London, E.C.

## New Trade Names.

RAINBOW.—No. 288,346. Photographic dry plates. Geo. Nelson, Dale, and Co., Limited, Emscote Mills, Wharf Street, Warwick, manufacturers of gelatine. November 28, 1906.

ALBAGLOSS.—No. 291,687. Chemical substances used in manufactures, photography, or philosophical research, and anti-corrosives. Joseph Chater and Sons, 2, St. Dunstan's Hill, London, E.C., glass, lead, oil, and colour merchants. March 27, 1907.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### The Chemistry of Ozobrome.

A diminution of the proportion of bichromate in the pigmenting bath (writes Mr. Raymond E. Crowther in "The Amateur Photographer") yielded prints which were relatively steeper in gradations and took longer to print than when using a normal bath. This is exactly the same result as that obtained in "light" printing under similar conditions. An increase of the proportion of bichromate in the pigmenting bath produced the opposite result. This explains theoretically the results obtained by Rev. H. W. Dick. To obtain strong prints he recommends the addition of a small quantity of ammonia to the working pigmenting bath. This ammonia simply has the effect of converting some of the bichromate into the chemically inactive chromate. (As far as could be judged by the experiments, the use of an alkali chromate in lieu of a bichromate is not permissible, and in this respect the chemical action seems to differ from the "light" action.) Conversely, the addition of an acid or alum to the pigmenting bath reconverts the chromate formed by the action of the hydrogen on the bichromate back into bichromate, and thus the proportion of bichromate in the bath is increased, fulfilling condition two above. It is possible, on the one hand, to completely check any action by the addition of sufficient ammonia, and on the other hand to so accelerate the action by the addition of acid that densely fogged pictures result.

## New Apparatus, &c.

The Tessar, Series I.C. (f/4.5) Anastigmat. Made by the Zeiss Works, Jena, and 29, Margaret Street, London, W.

This lens is one of the latest specimens of the Tessar type, and is specially designed for rapid hand camera work, for which purpose we could hardly wish for a better lens. At full aperture of f/4.5 it gives most excellent definition over a half-plate, though only intended to cover a quarter-plate. With the full aperture the illumination

naturally falls off towards the edges on the large plate, but the good definition at the margins shows that the lens is very highly corrected. Coma and astigmatism can barely be detected by a critical test on a small point of light, while on natural objects there is no evident sign of the presence of these defects. The field is almost absolutely flat, and there is no difficulty in securing good definition all over the plate when a near plane object is focussed upon, hence it would seem that the lens should be well adapted for projection purposes.

The objective is unsymmetrical and non-separable, and is composed of a powerfully convergent back combination and a negative front. The aluminium mounting is very highly finished and shows fine workmanship, and an unusual but useful feature is marking the diameters

of the various apertures in millimetres as well as by *f*-values. This Tessar should be of exceptional value for focal plane work, on account of its high correction, great rapidity, small size, and lightness. Many very rapid lenses that we have come across lately have been far too bulky and heavy to be at all convenient in use.

These new large aperture Tessars are made in two series, *f*/3.5 and *f*/4.5 respectively. The first are intended chiefly for cinematography and portraiture, the second for portraiture and instantaneous photography. These *f*/4.5 lenses are obtainable in foci from  $4\frac{1}{2}$  to 20 inches, the quarter-plate instrument which we have reviewed above being priced at £6 10s. The *f*/4.5 lenses are also made in focussing mounts, in the case of foci from  $4\frac{1}{2}$  to  $8\frac{1}{4}$  inches.

## New Materials.

"Ideal" Postcard Frames. Sold by O. Sichel and Co., 52, Bunhill Row, London, E.C.

This line of goods, which deserves to command the attention of the professional photographer, has been introduced by Messrs. Sichel in a very attractive form. The frames are in red or green leatherette, with struts to support them, either portrait or landscape way—that is to say, the single frame can be stood in both positions. The draw-

ings show a few of the patterns obtainable at prices which are certainly most moderate indeed. The line is one, in our opinion, which may be profitably worked in conjunction with the postcard portrait which, as offered to the public at the present time by many photographers, is not highly remunerative, to say the least. Messrs. Sichel's "professional" list should be consulted for sizes and prices.

**HALF-TONE POSTCARDS.**—Messrs. Hood and Co., St. Bride Works, Middlesbrough, send us some examples of their half-tone postcard work in reference to an offer now announced to supply a first-class card of this kind at a reduced price (8s. 6d. per 1,000) if the purchaser will allow 10 to 14 days for the execution of the order. This item of "tariff reform" does not affect the regular prices of 10s. 6d. per 1,000 for one or more thousands delivered in four or five days. Messrs. Hood, we are glad to see, preserve their standard of quality in work done at short and long notice, as instanced in a set of cards of the "Yeomen of the Guard" done last week when the "Mikado" was suddenly withdrawn at Middlesbrough. We say this after having seen cards shown to us by friends in the profession, who had commissioned Messrs. Hood to prepare cards from their originals.

Messrs. RAITHBY, LAWRENCE, AND CO., LIMITED (printers, of Leicester) have removed from 1, Imperial Buildings, Ludgate Circus, to Thanet House, 231-232, Strand, W.C. (opposite the Law Courts).

## CATALOGUES AND TRADE NOTICES.

"FRISIAN, LONDON."—The telegraphic address of Mr. S. H. Frisian, the trade enlarger and printer, of 5, Highbury Grove, London, is surely fixed in the minds of professional photographers. If it is not, the new catalogue just issued should compel its recollection from the brilliant and idealised three-colour view of Mr. Frisian's premises, which leaps from the cover. The price-list is a sign of order which pervades the Frisian firm, and ensures, as we know from our own inspection of its working, the rapid and economical output of high-class work. One convenient feature of the list is the use of red ink for all sepia-bromide work, a preventive of mistakes in ordering, which is good for both parties. We heartily commend it to the perusal of all needing enlarging and printing of all kinds.

"HANDY GUIDE TO PHOTOGRAPHIC REQUISITES" is the title of the latest price-list of photographic apparatus, materials, and chemicals issued by Messrs. Reynolds and Branson, Limited, of 14, Commercial Street, Leeds. The list is well arranged in an easily consultable form, and, each speciality being numbered, makes ordering by post an easy matter. Messrs. Reynolds and Branson will send a list to any of our readers, post free, on receipt of postcard to the above address.

**SECONDHAND APPARATUS.**—The monthly list of the City Sale and Exchange, 81, Aldersgate Street, E.C., which reaches our table, is a publication which may be recommended to anyone desirous of purchasing a new outfit and of disposing of his old one in part payment. With its three other establishments at Lime Street, Fleet Street, and Sloane Square, the "City Sale" has unrivalled facilities for quickly suiting customers' requirements, in proof of which the list reaches us before us or the weekly announcement in our advertisement page may be studied by the prospective buyer or seller.

MESSRS. GRIFFIN, Kingsway, London, send us the price list of chemicals made by the famous Berlin firm of Kahlbaum, for which they are agents. The chemicals are conveniently priced, per ounce and per pound, and the very comprehensive list should be useful to those needing substances of great purity.

MESSRS. RAJAR, LTD., of Mobberley, Cheshire, have issued a price list, containing the latest additions to their specialties, amongst which may be noted the new "Rajar" quarter-plate folding pocket camera, the special features of which render it particularly suitable for cyclomotorists, etc. There are also several new lines in paper and postcards, specially suitable for use by professional photographers. Messrs. Rajar, Ltd., will be pleased to send a copy of the list, post free, to any of our readers upon request.

MESSRS. BISHOP, of 466, Holloway Road, London, N., send us a copy of a supplementary list of their season's novelties, containing latest additions to their photographic stock, which is intended as a completion to the firm's large catalogue, issued a short time since. Messrs. Bishop state that they will be pleased to send a copy of the catalogue and list to any of our readers free on receipt of postcard to the above address.

**DEATH OF MR. CHARLES FERGUS.**—Many will regret to learn of the death of Mr. Charles Fergus, photographer, a well-known figure in many years in Greenock, which took place at Dunoon on May 10. Born in Ascog House, Bute, in the year 1835, Mr. Fergus was nephew of the well-known engineer of Greenock Waterworks, James Thomson. He went to America when twelve years old. Return twelve years later he started business as a photographer in Millport, and afterwards he joined his brother, Mr. John Fergus, in Largs, partner in the firm of Fergus Brothers. In 1863 Mr. Fergus opened the well-known business in Greenock, still carried on by his son, W. R. Fergus. He included among his customers the Duke of Argyll's family, Lady Crossby, Countess Roden, Drs. Norman George Macleod, Dr. Story, Dr. McGregor of Edinburgh, Mr. Sankey, etc. Possibly the best tribute to his memory as an amateur and photographer lives in the albums belonging to the Greenock Burns Club, which were executed from negatives mostly taken by him. For many years he was a member of George Square U.F. Church, now Greenbank U.F. Church. Of late years Mr. Fergus devoted himself to his Dunoon business, which he opened in 1891, finally going there to reside. He leaves a widow and four sons to mourn his loss.

 ins and Cope.

## PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

ETING of the General Committee was held at 66, Russell  
 e, W.C., on Friday, 10th inst. Present: Messrs. H. A.  
 an (Swansea), H. J. Comley (Stroud), A. Ellis, H. S. Fry,  
 n Jacolette, A. Mackie, H. S. Mendelssohn, D. Prodger, E.  
 ll, Lang Sims, C. H. Skillman, H. C. Spink (Brighton), and  
 lloWS Willson—Mr. H. C. Spink (president) in the chair. The  
 ecretary announced that the arrangements with the Fine Art  
 General Insurance Company for insuring members' liabilities  
 the Workmen's Compensation Act (1906), the Fatal Accidents  
 (1846), the Employers' Liability Act (1880), and at common law  
 now complete. The delay in the settlement of the matter arose  
 the fact that the principal insurance companies had only just  
 up their minds as to the tariff rate. This had been fixed at  
 each hundred pounds of salaries and wages payable. The  
 art and General Insurance Company had adopted this rate for  
 ordinary policies, but members' insurances would be subject  
 same allowance as that made on fire insurance—a discount of  
 cent. The hon. secretary also reported that the new hand-  
 ad been issued to the members. It had been found necessary  
 arge it by four pages. The legal and general information con-  
 ng matters incident to the carrying on of photographic busi-  
 ad been revised and considerably added to, and every effort  
 en made to make it an indispensable work of reference on all  
 of professional practice. It was agreed to repeat the full-  
 advertisement, which appeared last year in the BRITISH  
 AL OF PHOTOGRAPHY, of the Association and its aims and  
 ages. Experience had shown that the cost had been repaid by  
 ession of new members. The hon. secretary was authorised to  
 se any reference books necessary to enable the committee to  
 with questions that members might put concerning the laws  
 g to employers' liabilities. A letter was read from Mr. T. C.  
 (Hull) relating to the growing demands of the theatrical pro-  
 for free photographs. After discussion the president under-  
 convey the sense of the meeting to Mr. Turner.

## ROYAL PHOTOGRAPHIC SOCIETY.

re held May 14, Mr. J. C. S. Mummery (president) in the chair.  
 airman announced the presentation to the society of a camera  
 the late Colonel Gale; the thanks of the meeting were recorded  
 donor, Mr. Berell. The gift also of a collodion positive on a  
 material, by Mr. T. Horne Redwood, was acknowledged with

E. T. Holding then delivered a lecture, entitled "The Camera  
 e," in which he dealt with the making of the photographic  
 studies with which his name has been associated at the  
 ions. Mr. Holding prefaced his subject proper with some  
 s on photography and art, in the course of which he said that  
 main of figure study work offered even more difficulties than

did landscape, a fact which perhaps accounted for its being less taken  
 up by amateur photographers, although the attraction of the outdoor  
 life necessary to landscape photography was no doubt responsible for  
 the large proportion of work of that kind which was exhibited. Still  
 he could say that, as regards expression of form, tone, and composi-  
 tion, the photographer was less handicapped in figure work than in  
 landscape, because he had the power to adjust his conditions to a  
 greater extent than in landscape. Yet however good the technique,  
 continued the speaker, the result was without particular merit if it  
 lacked imagination or if it evidenced no possession of that innate good  
 taste which was well described as "the cultivated appreciation of the  
 beautiful."

Mr. Holding commended the study of Mr. George Clausen's "Aims  
 and Ideals in Art," where it was stated that taste in a picture was  
 much the same kind of thing as naturally good manners in a man,  
 and the true artist looked for qualities in a picture corresponding  
 to those which he would look for in a friend. Passing to the views  
 of Mr. Bernard Shaw on photography, Mr. Holding could not attach  
 any meaning to Mr. Shaw's inaccurate aphorism which exalted the  
 telephoto lens above "that clumsy tool," the human hand. If  
 Mr. Shaw's dictum meant anything at all it meant that there was  
 no more art in the use of a pencil or a brush than there was in  
 projection by a lens. Mr. Holding condemned the drastic improve-  
 ment of the photographic rendering of a subject by hand, a practice  
 which, he said, led one to assume that there was nothing beautiful  
 in Nature; as a matter of fact, it was usual to see many photographs  
 of actually beautiful scenes spoilt by inartistic tinkering. Passing  
 to the practical side of his subject, Mr. Holding first dealt with  
 portrait and figure study work out of doors, for which he recom-  
 mended a white background against which it was possible to show  
 up the light tones in the drapery of a figure. For indoor work either  
 a light or a dark background might be used. He used one white on  
 one side and dark on the other, supporting it, with either face  
 towards the camera, by means of a bamboo frame about six feet  
 square, which was strong enough to support a picture or ornament  
 should such be required in the composition. He illustrated the  
 methods of dealing with indoor lighting by means of a number of  
 altogether charming examples of studies of women and children. An  
 interested audience marked their appreciation of these studies in  
 light, tone, and posing by frequent applause.

In the subsequent discussion, which wandered from the subject of  
 Mr. Holding's paper, Messrs. Maclean, P. Bale Rider, Dr. Evershed,  
 and the chairman, took part.

**CROYDON CAMERA CLUB.**—The president (Mr. A. E. Isaac) last  
 week gave an interesting little chat on hand cameras, several new  
 models by Messrs. Houghton and Messrs. Butcher being examined  
 with much attention. The lecture concluded with an animated  
 discussion.

**CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.**—On Wed-  
 nesday, May 8, Mr. Clougher read a most interesting paper on  
 "The Cinematograph," Messrs. L. Kamm and Co. having kindly lent  
 one of their cinematographs. A practical demonstration was given.  
 The author said that probably the earliest form of slide in which an  
 attempt was made to show movement was the "slipping slide," in  
 which one part of the figure was obscured while another part was  
 shown, and *vice versa*, by means of a painted glass moving behind  
 the picture slide. In 1860 Desvignes invented the zoetrope, or  
 "wheel of life." Although now regarded as a plaything, it was at  
 first a decidedly scientific instrument, which opened up a line of  
 investigation ending in the intricate instrument of the present day.  
 The fundamental truth on which the zoetrope was designed, and  
 which underlies the whole of cinematography, is the persistence of  
 vision, which, as applied to this subject, means that if an object or  
 picture is seen in the same place 8 to 24 times a second it will  
 appear as if seen continuously. Hence, if in each successive picture  
 a certain spot is reproduced as having moved a small distance, and  
 the pictures are shown in rapid succession, the spot will appear to  
 be moving across the plane of the screen. The author next ex-  
 plained how the pictures were taken and projected. The film had to  
 be stationary during exposure, and the light cut out while it is  
 moving. Several methods of intermittently rotating and stopping  
 the wheel which drives the film were then explained by lantern  
 slides. The film is wound on a spool above the machine. From

here it passes through the "film gate" and then around a sprocket wheel, which is intermittently moved by one of the arrangements described. Gearing to the driving wheel is a shutter, which cuts off the light while the film is moving. A sprocket is now also fitted above the gate to take up the pull required to unwind the film. Since the film is inflammable and the picture small, the heat from the illuminant is concentrated over a small area, and there is danger of fire if the machine is stopped and the light left on. Therefore, an automatic shutter, worked by a governor, is often fitted to obscure the light from the film when the machine is stopped. The Edison gauge film is practically the standard now. It is 2 11-32 in. wide, and the picture lin. by ¾ in. There are four perforations to each picture. An arc or lime light is the usual illuminant, but it is essential that the light be more than 1,000 c.p. Mr. Clougher then explained Mr. R. T. Haines's method of duplex projection for doing away with the flicker. The film is printed in a double column, alternate pictures being in the right and left columns respectively, the successive pictures not being opposite each other. There are two projectors, although only one light, and by this means there is always one complete picture on the screen. Other branches of cinematography referred to were stereoscopy and moving pictures in colours. A very successful two-colour machine was one invented by Mr. Freese Green. The film has two pictures side by side, each being taken through a proper coloured filter. A positive is made from the negative thus obtained, and the two pictures projected through suitable filters and superimposed on the screen. There is only one instance in which glass has been successfully substituted for film, and this is in the case of Messrs. Kamm's kammatograph, in which the pictures are taken in a spiral form on a circular glass plate. Mr. Kamm kindly lent a machine for demonstration purposes. The usual speed of taking pictures is 16 pictures—i.e., 1 ft. of film per second—but this may be varied, and therein lies the difficulty. It is very seldom that the same person takes the film who exhibits it, and thus an altogether untruthful idea may be produced. The author therefore suggested that all taking and projecting machines should be fitted with speed indicators, so that by recording the rate at which the film was taken it could be exhibited at the same speed. The author laid great stress on the scientific value of the cinematograph for educational purposes, and said that every technical college should possess a machine. He also referred to the extremely interesting work done in microcinematography by Mr. Martin-Duncan, and also the works of Mr. Chas. Urban. The following films were shown: (1) The life of a bee (Chas. Urban and Co.); (2) The manufacture of steel rails (Chas. Urban and Co.); (3) Across the Alps; (4) Climbing the Alps.

## Commercial & Legal Intelligence.

**EASTMAN KODAK COMPANY, OF NEW JERSEY.**—The usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding preferred stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding common stock, have been declared by the Eastman Kodak Company, of New Jersey, payable on July 1, to stockholders of record on May 31, 1907.

**CERIO PHOTO PRINTING COMPANY, LTD.**—Lien registered May 1, for £2,700 six per cent. debentures, part of £5,500 authorised; no trustees charged on the business and assets, present and future.

**WAGES OR NOTICE.**—At the Clerkenwell County Court last week, before his Honour Judge Edge, an action was brought by Robert Melville, accountant and foreign correspondent, of 50, Crayford Road, Holloway, against Messrs. Underwood and Underwood, stereoscopic publishers, of 103, High Holborn. The claim was for £72 11s. as damages for alleged breach of contract. Mr. Ward was counsel for plaintiff and Mr. Thomas for defendants. The case came before a jury.

Plaintiff said that in May, 1905, he was engaged by Mr. Ross, defendants' general manager, as book-keeper and foreign correspondent. He was engaged at a salary of £180 a year, to be increased to £200 at the expiration of three months' trial if his services proved satisfactory. He commenced his engagement on May 23, and threw his best energies into the work, which entailed a lot of overtime. In three months there was an increase of 94 per cent. on the sales of

agents compared with the corresponding three months. On the sale of photographs this was 15.9 per cent., and on the sales to which the increase was something like 500 per cent. Mr. Ross expressed himself thoroughly satisfied with his work, and paid him up to the rate of £200, and later on his salary was increased to £240. August, 1906, he spoke to Mr. Ross about his private letters being opened, and Mr. Ross said that in future his letters should not be opened. Continuing, he said that on December 22, 1906, he received a letter from Mr. Foote, one of the agents in Berlin. That letter contained a present of a £5 note. It had been opened by some one in the office, and Mr. Ross, on handing it to him, said, "You ought to divide that with other members of the staff," or words to that effect. On carefully considering the matter, he informed Mr. Ross that though the £5 was intended for himself, and he should keep it, January he had been working hard and was feeling unwell. He finished up his work and took a day's rest, but on the following Friday he found that 15s. had been deducted from his wages, so he declined to take it. On the Saturday he was informed that his salary would be reduced from £20 per month to £4 per week. He declined to accept the reduction, and on the Monday morning he tendered his services on the old basis. Mr. Ross said he could not agree to that, and told the cashier to give him £4 10s. as the balance of salary. He declined it, because there was more due to him.

Mr. Ward: Did you receive any notice from Mr. Ross at that time? As a servant at a yearly salary what notice ought to have been received?—I consider I was entitled to three months' notice. It is a post such as you fill a difficult one to obtain?—Yes, I think it is.

How long were you out of work?—Six or seven weeks. For the defence Mr. Ross, the defendant's manager, said that when the engagement was made it was agreed that plaintiff should receive £3 10s. per week for two months and £4 per week afterwards. He never agreed upon £180 as a yearly salary. Plaintiff was paid week like the other employees. When plaintiff complained about overtime his wages were increased, and he was also given tea and Letters were constantly being addressed to plaintiff on the firm's business, and in the ordinary course these were treated as business letters and opened. Mr. Foote, the Berlin agent, was one of the leading customers, and as letters were frequently received from him witness knew his handwriting well. With regard to the letter in question, he had no idea that there was anything private about it, and thinking it was on the business of the firm, he opened it. When he handed it over, plaintiff seemed very much surprised to find the £5 note had been sent him, and asked witness what he had been doing with it. Witness informed plaintiff of the firm's rule regarding gratuities, and said it would be better to divide it all round. Continuing, witness said that when plaintiff made more complaint about the overtime, he told him that he should not work any more overtime, but that in consequence of his lessened services his wages would be reduced to £4 per week. On the Monday plaintiff wished him to sign a paper, reinstating him on his former wages, but refused to do so. Plaintiff then left. As to the increase of business all the employees contributed to that.

The jury replied as follows to questions submitted by the Judge: Was the plaintiff's engagement a weekly or yearly one?—Yearly. Having regard to plaintiff's position, what notice would be a reasonable notice?—One month. Did Mr. Ross refuse to continue plaintiff in defendants' service on the terms agreed upon in February, 1906, viz., £4 10s. per week and 10s. extra per month?—Yes. The jury added that they awarded no damages.

The Judge: But you must award something on this finding. Upon his Honour's direction the jury awarded the plaintiff £20, one month's salary in lieu of notice, and £4 15s. as money due to him.

Mr. Thomas: That is £24 15s. We have paid £25 into Court, I ask that the verdict be entered for defendants.

### NEW COMPANIES.

**J. HALDEN AND COMPANY, LTD.**—Capital, £40,000, in £1 shares. Objects: To acquire the business carried on in Manchester, London, Newcastle-on-Tyne, and elsewhere, by J. Halden, G. F. Pringle, & J. R. Ball, as "J. Halden and Company," and to carry on the business of manufacturers and sellers of drawing materials and papers, mathematical instruments, and specialties, photographic copying apparatus, engineers' photo and copying process materials, photographic materials.

and cinematograph instruments. No initial public issue. The directors are: J. Halden, G. F. Pringle, and J. R. Ball (permanent governing directors), W. A. Halden, W. Monkhouse, W. V. n, H. R. Watts, R. F. Moir, L. Wordsworth, and E. W. M. r. Qualifications of permanent governing directors, £1,000; of directors, 50 shares. Remuneration of governing directors, £400 per annum. Registered office: 17, Altrincham Street, Manchester.

DDOCK, LTD.—Capital £500, in £1 shares. To take over the ess of photographers carried on by A. Lewis and P. Lewis, at Whiteladies' Road, Clifton, as "Abel Lewis and Sons," and to an agreement between the said vendors and R. E. Ruddock. Initial public issue.

NDON AND PROVINCIAL STORES, LTD.—Capital £3,000, in 10s. s (3,000 preference). To carry on the business of clothiers, tailors, al outfitters, jewellers, watch and clock makers, photographers, rs in photographic requisites, optical and scientific instruments, ccessories, cycle and motor dealers, booksellers, etc. No initial e issue. The number of directors is not to be less than two nor than five. The first are: E. E. Farmer, A. W. Thomas, and A. Thomas. Remuneration (except managing director) as fixed e company. Registered office: 44, Gray's Inn Road, Holborn,

## News and Notes.

TOGRAPHER AS "PASSIVE RESISTER."—The sale of certain effects r. H. A. Chapman, J.P., photographer, and an ex-mayor of sea, last week, by the Swansea collector of income-tax, rendered sary by the determination of Mr. Chapman to protest against his ment, went off without the anticipated fun. Mr. A. J. Gear, hief official, attended the sale himself. There were 30 or 40 ns present in the studio when the sale took place. Mr. Gear y read the conditions of the sale, and then asked for bids for merican organ which had been seized. It was a handsome e organ, which years ago figured in a Swansea chapel, and has een used by Mr. Chapman as an accessory to his studio. It ppraised by a local music dealer at £10. The bidding reached t which it was knocked down to Mr. John Hansard, who, it aid, was acting for another person. Mr. Chapman was present, dpressed several remarks to the reporters, and after the sale he ted that someone should play the Doxology on the instrument, aid he, "I feel inclined to sing 'Praise God, from Whom all ngs flow.'" It is rumoured that certain brother tradesmen of Chapman intend to restore to him the instrument and reimburse gainst loss.

DEMACHY EXHIBITION.—M. Robert Demachy, we learn as we press, is holding an exhibition of examples of his work by the ocess at his Studio, 45, Rue Hegesippe, Moreau. The exhibi-as open Tuesday and Wednesday last, May 14 and 15. The s are to be seen next month at the Royal Photographic Society's . In connection with their exhibition an address by M. chy will be delivered.

LEPHOTO HOOD.—In reference to the notes on Captain Owen ler's hood in last week's issue, Messrs. R. and J. Beck, Limited, ornhill, E.C., inform us that they will shortly have ready for market a neat aluminium extending hood for attaching to the e of a lens when used for telephotography.

NET CASH PRIZE COMPETITION.—The results of this competition, in connection with the issue of the sample packets of the new ter-shell" gaslight paper, was as follows: 1st prize, 21s., John l, The Bungalow, Woodhall Spa; 2nd prize, 10s. 6d., Miss l Ferguson, 23, Heathfield Road, Oxtou, Birkenhead. Awil prizes of 5s. each to Harold Blades, Brow Hill, Leek, Staffs; . Gales, The Poplars, Dartford; Herbert E. Grigg, 31, Neal t, Spon Lane, West Bromwich.

RO-PRUSSIAN PAPER.—In reference to the paragraph on "Ferro- late Printing" last week, the British Photo-Paper Company, ed, Guildford Street, York Road, Lambeth, S.E., write us: should like to say that if Mr. Josiah Martin would care to try t of our ferro-prussiate paper for daylight printing he would hat such an appliance as an actinometer is quite unnecessary y any conditions, whether a dull and cloudy or a bright sunny

day. He would also see that it is in no way difficult to determine the proper exposure."

NEW GLASSES.—Mr. F. A. Lindemann and Mr. C. L. Lindemann, writing to "Nature," describe a new glass which is transparent to rays of very short wave-length. They have found that lithium biborineum,  $\text{Li}_2\text{B}_4\text{O}_7$  (ordinary borax in which the sodium is replaced by lithium), when fused produces a clear glass which shows no appreciable absorption in the ultra-violet spectrum above  $2,000 \text{ \AA}$ . In order to determine the absorption below this a vacuum spectrograph would naturally be required, as the air absorbs any lines shorter than  $1,856$ . The refractive index for the D-line  $n=1.5389$ , the dispersion  $\Delta$  between  $e$  and  $F$ ,  $\Delta = 0.00847$ , and  $v=n-1/\Delta = 63.7$ . As might be expected, owing to the large percentage (82.5) of boric acid, the dispersion toward the red side of the spectrum is fairly large, whereas that toward the violet side is very small. The glass is extremely transparent to Röntgen rays, which it lets through, roughly, ten times as well as ordinary glass. The specific gravity is 2.2; the hardness, 6. The glass can be cut and polished without difficulty. The cubical expansion coefficient (calculated from the constants of Winkelmann and Schott) is  $118.10-7$ , about half that of ordinary glass. It has been found that, as a general rule, the transparency for rays of short wave-length increases in analogous salts as the atomic weight of the metal decreases, but sufficient experimental data have not yet been obtained to warrant the publication of a definite opinion.

It is announced from the Carnegie Geophysical Laboratory in Washington that quartz glass can be successfully manufactured, but the authorities of that institution decline to commit themselves as to its feasibility from a commercial viewpoint. The chief value of quartz glass over ordinary glass is found in the fact that it can be heated to a temperature of about  $1,000 \text{ deg. C.}$  without softening, and its expansion under ordinary heat is so small as to be almost a negligible quality. It thus can be heated red hot and plunged into cold water without in the least cracking. It has the distinct property of permitting the passage of ultra-violet light rays, making it remarkably valuable in photographic uses.

At the Carnegie Laboratory many methods of preparation were tried before definite satisfactory results were obtained. If the quartz was intensely heated, free silicon was deposited on the inside of the air bubbles, and the glass was spoiled. The final solution of the problem was found in heating the quartz to the melting point, about  $4,000 \text{ deg. Fahr.}$ , and then subjecting it to an air pressure of between 400 and 500 pounds. After this it was allowed to gradually cool. The air pressure squeezed out the air bubbles, and the result was a solid and clear mass of quartz glass. The plates so far made at the laboratory are only about three by five by half an inch in size. The bubbles are few, not over one-half a millimeter in diameter, and are not frequent enough to interfere with the use of the glass for lenses, mirrors, and other optical work. With more skill and experience the glass can be made without the flaws which confronted the workers.

THE IMPERIAL "HANDBOOK."—In issuing the 1907 edition of their "Handbook" the Imperial Dry Plate Company, Limited, has adhered to its previous policy of providing a variety of technical information, much of which is old, yet cannot be too often repeated, for each year must witness the entrance into the photographic field of many whose neglect of these elementary precautions is the sole cause of their photographic failures. Therefore we can warmly recommend our dealer-readers to use the Imperial "Handbook" as a rapid and satisfactory method of answering questions, and the same recommendation may be given to all who are consulted on the elementary matters which are very clearly treated in the 1907 issue. Among these are "Notes on Exposure," "Dark Room," "Solutions," "Development," "The Fixing Bath," "Washing and Drying Negatives," and "Backing." It is not too much to say that complete digestion of the hints conveyed in these chapters would relieve the troubles which overtake the beginner in negative-making. There are two other articles—on "Bromide and Gaslight Printing," and on "The Making of Pictures."

THE LONDON SKETCH CLUB.—A very choice little exhibition is open at the New International Gallery in King William Street, W.C., where the members of the London Sketch Club have placed their annual show of work. The reception last Saturday was so well attended that anything beyond the merest glance at the pictures

was impossible. The heat and the crush shortened our visit; but we were well impressed that the little display is one of high merit and unusual interest.

**COMBINED OUTING OF THE LONDON PHOTOGRAPHIC SOCIETIES.**—The South London Photographic Society are this year taking the lead in the annual outing. The date fixed is June 8. Train will be taken to Claygate Station, proceeding thence to Oxshott and Esher, where tea will be served, finishing up with a concert and conversazione. It is hoped that all London societies will be represented, and as many members as possible attend, so as to make the function a success. All information may be had of the secretaries of the various societies, and further particulars will be announced in the photographic Press in due course.

**COALVILLE PHOTOGRAPHIC SOCIETY.**—At the National Schoolroom, last week, Mr. Walter Lindley, C.C., presided at a well-attended meeting convened to consider the formation of a photographic society for Coalville and district. After some discussion Mr. Thomas proposed that a society be formed. This was seconded and unanimously carried. About 30 joined the society. Mr. Walter Lindley, C.C., was elected president, and Dr. Jamie, Mr. R. Blower, and Mr. B. G. Hale vice-presidents, Mr. Thomas hon. secretary, and Mr. G. Gutteridge treasurer. Arrangements will be made for monthly excursions in the summer, and lectures and demonstrations in the winter. The society will be affiliated to the Royal Photographic Society.

**HOW TO LOOK ONE'S BEST IN A PHOTOGRAPH.**—A booklet bearing this title has been issued by Messrs. H. J. Gover and Co., photographers, of 53, Piccadilly, Hanley, evidently for gratuitous distribution among the public in that district. The booklet contains some useful advice to sitters, and we are interested in noting a prominent announcement that proofs "are charged for, whether ordered from or not." Such a stipulation on the part of the photographer is only right, though it is a matter for each to decide for himself whether the sitter should not be given the option of returning the proofs instead of paying for them.

**FROM THE HEALTH RESORTS DEVELOPMENT ASSOCIATION,** 29, John Street, Bedford Row, London, W.C., we have received copies of guide books which have been issued for the Town Councils of Bournemouth, Tenby, and Weymouth. These booklets contain illustrations of the towns and surrounding districts, together with information as to the chief features of the neighbourhood and the facilities for reaching them either by sea or land. Particulars as to hotel and boarding-house accommodation are also included, and intending visitors may be glad to know that they can obtain a copy of the booklet, post free, by sending a postcard to the respective town clerks.

**THE CROYDON CAMERA CLUB EXHIBITION** will be held November 20 to 27 next at the Art Gallery, Park Lane, Croydon. There will be open classes as usual, and free carriage will be provided from the Hackney Exhibition for exhibits entered at both shows. The exhibition secretary is Mr. H. T. Dodsworth, 93, Woodside Green, Croydon.

**TELEGRAPHIC PHOTOGRAPHY.**—It will be of interest to our readers (writes "The Inland Printer"), after having read the comments in relation to the recent experiments with the Korn method of picture transmission to know that the system as explained therein in fundamental principle is practically the same as was described by N. S. Amstutz, who is now principal of the "Inland Printer" Research Department, in London in 1899. This feature, among others, is also disclosed in a United States patent issued to him in 1899. Mr. Amstutz has not surrendered the field of photo-telegraphy. He is engaged in carrying forward private researches that have to do with the greater perfection and the automatic receiving of the result in the shape of a medium that will at once lend itself to direct relief engraving reproduction without the intervention of complicated photographic processes.

**THE FOURTH AMERICAN SALON** is now in active preparation, and the pictures contributed to the Third Salon will be despatched from the States about the middle of July. The success of the Salon has strengthened the Federation of Photographic Societies to such an extent that the managers are arranging for the exhibition to go to a number of new cities, and therefore to have a longer season. The result of this is that the entries will close in America on September 15, therefore we presume (though the date is not actually

fixed) that the British entries must close about August 15. Before, the pictures will be collected and forwarded by H. Snow Ward, 6, Farringdon Avenue, E.C.

**THE "ZIGAS" PROFESSIONAL COMPETITION.**—We may draw attention to the competition of Messrs. Illingworth and Co., Limited, Willesden Junction, N.W., in which a first prize of £20 and others, amounting in all to £40, will be awarded for the examples of professional work on the "ordinary" and "portable" grade of this gaslight paper. June 30 is the closing day for entries. Messrs. Illingworth's circular gives full particulars of competition, in which amateurs are ineligible.

**APPARATUS SALE.**—Messrs. John J. Griffin and Sons ask to notify the closing, on May 30, of the stocktaking sale of cameras and other apparatus at great reductions. "Crytho" cameras, at 38s. are offered for 8s. 9d., and the leaflet obtainable from the premises, Kingsway, London, discloses other low prices.

## Correspondence.

- \**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

### A WAVE OF ORTHOCHROMATISM.

To the Editors.

Gentlemen,—May I be permitted to reply to your editorial remark of last week, and to sincerely congratulate you on the appropriateness of the quotation referring to "Truth new-born"? Taking cardinal virtue in the restrictive sense applied, on your own show it is well over age, and, if still "mis-shapen and of untimely growth," a little more time should yet be allowed for the poor "rule-of-thumb man, the man who makes 'hopeless infantile caricatures' of ordinary plates, to appreciate its full beauty.

Throughout your special pleading I cannot help noticing that my observations, which might be construed as inimical to orthochromatism, to put it very mildly indeed, were accentuated by you, my hearty appreciation of colour-sensitive plates and their possibilities were not even referred to. I fully and cordially agree with your statement, and my paper clearly inferred that "orthochromatism" is "merely a reserve power," and, I would add, a valuable one; but I must confess I feel at a loss to understand how you should apply this limitation, considering the denunciation of ordinary plates, owing to the wrong values obtained by them. These are so bad then it would, or, rather, ought to, be possible in all cases, except when rendering black and white, to say with certainty that such and such a print was the product of a screened ortho plate, or of an ordinary plate. We all know this cannot be done. Again, if the advantages of the former are so patent, the disadvantages of the latter so obvious, what a pile of duffers the great majority of photographers of the present day must be, in not immediately grasping salvation values." Think of the vitiated taste of our exhibition judges who have habitually medalled pictures taken on plates coated with "Ananias" emulsions! May the shade of George Washington ever haunt them.

I join issue when you say that the greater difficulties of working ortho plates are not dependent upon the plate, but on the operator. For one thing, the difficulty of estimating the correct exposure of a screened ortho plate is undoubtedly increased, and one is more likely to meet with failure from under and over-exposure. To argue that this is the fault of the operator is to argue in a vicious circle. There are other points which might be raised, but I refrain from incurring further editorial wrath.

As to the question of gradation, we have been taught, at Croydon Camera Club, that a screened ortho plate gives different gradation to that obtained by an unscreened one, or an ordinary plate. Possibly Dr. Mees might throw some light on this. In reference to the loss of *quality* alluded to by me, I am quite ready to admit that, in attempting to define what may be almost undefined by my words might be reasonably taken as having a more extended meaning than was intended. However, I maintain, and my opinion

by others, even if we cannot "rationally express ourselves," there is a certain loss in some directions when using screened plates. To take another case. It is not easy to define the quality which almost invariably occurs when, say, a pen and ink drawing is reproduced by any mechanical process.

In answer to your pointed question as to whether I should prefer to go on a holiday with an extra five-pound note in my pocket for merely enough money for bare necessities, let me at once say that I should infinitely prefer the addition of the "five." Should I arise, it will give me pleasure to take advantage of the offer of a holiday made and conveyed with the utmost delicacy and nicety. Yours faithfully,  
E. A. SALT.

To the Editors.

Gentlemen,—It is a little difficult to see what is being driven at in your referred to in your last issue, as the writer clearly recommends ortho plates for certain subjects. Personally I cannot say I noticed any lack of "go" in them. Without a screen for landscape work they give, in my experience, rather better results than on an ordinary plate. With a screen the danger seems to lie in loss of atmosphere. There are some days, however, as Ruskin says, "all the air is full of light," and there is practically no land visible, what we usually term atmospheric effect. It was so in the three photographs taken. No. 1, on an ordinary plate (seascape) gives the coast line about three miles off shore. No. 2, on ortho plate, with screen, gives the coast line about 14 miles off through the reflecting blue from sea and sky. No. 3, on ortho plate, with screen, with a nearer coast line, and clouds.

Now I think you will say there is pluck and go in No. 1, I think if anyone could say that Nos. 2 or 3 lack in pluck or have the process look about them. Is it not, after all, a question of your tools?

On wet-plate days for landscape work we purposely made our work slow, and I think it holds good to-day that for distant subjects the slower plates are best, yet there are so many subjects you want distance and yet wish to catch some moving subject in the foreground, perhaps, that one is obliged to use the faster and even of the ortho kind, discard the screen, or else lose the prominent portion of the picture.—Yours, PROFESSIONAL.  
Nos. 1 and 2 very strongly emphasise the advantage of the ortho plate. The second is a good rendering of a brilliant scene.—Eds., "B.J."]

To the Editors.

Gentlemen,—Are we living in the year 1907 or 1873? I am led to this from your report of Mr. A. E. Salt's remarks on page 379 of your Journal, dated the 10th, because, if I am in error, and I can, to a certain extent (only), understand these remarks, for any photographer at this late date to give expression to altogether beyond me. He says there is "some subtle difference, the difference of tone value, and tone value alone," he says, "judged by the usual standards." What, may I ask, are the usual standards? Are they the old false standards, that in a photograph a blue must be rendered white and red a black, or standard of colour rendering? I am willing to grant him that flower studies may be fairly well rendered by the use of the ordinary plate and prolonged exposure, but even these are better when an iso. plate and suitable filter are used. That very professionals use iso. plates may or may not be true; if it is, because they do not yet understand their value, and my experience tells me that professionals are the very last of all photographers to take up any new thing that will vary their working methods ever so little.

Now, I may state distinctly that orthochromatism has not to do with us; would that it had raced a little further than that, and, may I add, that ortho plates, used with ordinary care, everything that the ordinary brands will do, be it copying and white, landscape, or portraiture, and do it better.—Yours faithfully,  
ERNEST HUMAN.

St. Paul's Park, E., May 13, 1907.

My correspondent is to lecture upon a subject cognate to the one in the L. and P. next Thursday, the 23rd inst.—Eds. "B.J."]

## LOCATIONS FOR FACTORIES.

To the Editors.

Gentlemen,—As chairman of the New Industries Committee of the Dunstable Town Council may I draw your attention to the fact that our committee has collected very useful information available for those wishing to remove from congested districts. We have persuaded the land owners to take a low price for land, and there are many other valuable considerations.

As a photographer I am a diligent reader of the "Journal," and it has occurred to me that there may be manufacturers in connection with some branch of photographic materials who may be desirous of finding a suitable locality. If any such will communicate with us we shall be pleased to afford them any information they desire.—Yours respectfully,  
JAMES FIELD.

75, High Street, Dunstable.  
May 10, 1907.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 2A, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 2A, Wellington Street, Strand, London, W.C.

\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 2A, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

W. Moline, 9, The Avenue, Clifton, Bristol. Photograph of Door, Laigton Mansion, Bristol.  
P. A. Zullock, 2, South Street, Hucknall Torkard, Notts. Photograph of the Rev T. G. Barber, M.A.  
T. V. Richards, 60, St. John Street, Galashiels, N.B. Photograph of the Rev. A. A. Jenkins.  
C. G. Caldecott, 24, Regent Street, Wrexham. Photograph of St. Giles's Church Tower, Wrexham, North Wales.  
Mowll & Morrison, 45, Hardman Street, Liverpool. Two Photographs of the Rev. J. Watson, D.D., M.A.  
H. D. Wootton, 63, Albany Road, Redruth, Cornwall. Photograph of Scroll and Photograph of Casket Presented to Sir Wm. F. Treloar.

### PAINTING REGISTERED:—

B. T. Hugh, 35, High Street, Chatham, Kent. Painting entitled: "On Every body's Tongue."  
E. G. T.—A thin solution of dextrine is usually used with or without the addition of alcohol, which makes the coating dry more rapidly. A preparation made as follows has also been recommended: Add an excess of powdered dextrine to barley water, stir for a minute or two, allow to settle, and strain through a fine cloth.

VARIOUS.—(1) Is an employer bound to give his employee (an operator assistant) a reference, provided he left honourably, etc.? (2) How long should sulphocyanide bath (gold added) keep in corked bottle—"Solio" formula? (3) Should it be made up fresh and used, or left, say, twelve hours or so to ripen?—SULPHOCYANIDE.

(1) He is not bound. (2) Before use it should keep for at least a month. Its keeping properties depend on the purity of the sulphocyanide and of the water. (3) Unless made up with hot water (when it is ready for use as soon as cold) it should be allowed twelve to twenty-four hours to ripen.

H. W. MINETTE.—The facts which you state do not account for the trouble. A freshly-made hypo bath of the unnecessarily great strength which you use would be a predisposing cause, as it would greatly chill the films. We can find no other explanation of this very uncommon occurrence.

AVOIDING REFLECTIONS.—Could you kindly let me know of anything that would prevent reflection when photographing lace under glass, as it has been done on enclosed proof?—A. FINN.

The only way to prevent reflections is to drape everything which may be reflected in the glass in black—that is to say, the camera itself should be draped with a dark black cloth and a black screen placed on each side of it, so as to shield it from all objects which

might be reflected in the glass. Our own plan is to get a black screen of silesia lining, about 12ft. square, and erect it close behind the camera by means of a couple of bamboo rods. We think if you do this and use a slower plate and a stronger developer than you appear to have been doing you would gain the necessary vigour in the negative.

**COLLOTYPE.**—Could you let me know two or three of the best practical books (in English) on the colotype process, and where I could obtain them?—**PRINTER.**

"Practical Colotype," by A. W. Fithian (11ffe, 2s. 6d.). Also "Photo-Mechanical Processes," by W. T. Wilkinson (Hampton and Sons, 4s.).

**EMULSION WASHING AND COATING.**—(1) How long will it take to wash the gaslight emulsion? (2) I am making a machine for coating the cards in 3ft. lengths of cardboard, for it to travel on rollers. Is it advisable to level it on glass or hang it straight up to dry from the emulsion? I have a good room to work in.—**J. HARRIS.**

(1) The time of washing depends entirely upon the fineness of the pieces of emulsion, the amount of water, etc., but six hours should be enough, provided there is plenty of water to move about. (2) It is advisable to let the cardboard travel straight up for about six feet if a dipping-roller is used, or if it is coated flat on the glass, then it can be hung up as soon as the emulsion has set.

**DAGUERRETYPE.**—Beyond removing with a soft camel's hair-brush any dirt or dust between a Daguerreotype and its protecting glass, is it possible to attempt anything in the way of restoration or the removal of stain?—**W. H.**

Tarnish may be removed with a weak solution of potassium cyanide. The process is a delicate one (see "Almanac," 1907, p. 767), and is best left to skilled hands. One Daguerreotypist who undertakes such work is Mr. E. W. Foxlee, 22, Goldsmith Road, Acton, W.

**ALPINE PHOTOGRAPHY.**—Would you kindly say what is the best plates to use for taking Swiss scenes, ordinary or orthochromatic plates, quick or slow? We want to get some views of the mountains with valleys.—**SWISS.**

We should prefer as rapid an ortho plate as can be got with a medium screen. You will find some useful hints on the development of mountain subjects in "Photography on Tour" (Dawbarn and Ward, 1s.).

**A. J. LEWIS.**—"The Photographer," 21 and 26, East Twenty-first Street, New York. My dear sir, have you not seen the reports of the convention of the Professional Photographers' Society of New York, in our columns of late?

**MERCURY TONING.**—Please let me know if a bromide print, intensified with mercury, and image regained with ammonia, is supposed to be permanent or not.—**M. B.**

It cannot be called permanent. The process is the least satisfactory of its kind. Ferrous oxalate developer or sodium sulphite is better as the darkening bath.

**HISTORY OF PHOTOGRAPHY.**—Will you kindly inform me where I can obtain, either by loan or purchase, a set of prints, photographic or otherwise, illustrating the early history and evolution of photography. I want them for an exhibition, to be displayed on a board, so that a book would not be suitable for my purposes.—**THOMAS B. LATCHMORE.**

There are no prints available so far as we know. "The Photographic Monthly," 6, Farringdon Avenue, E.C., lends a set of slides on the subject.

**INSTRUCTION FOR 2d.**—I bought the enclosed at Morecambe last week from a person selling these instructions. I gave 2d. for them. There was a paper negative and four pieces of printing paper. I could print a good photograph from the negative given with the instructions, but I have tried to print some from some photographs I have of my own and I cannot do them. The person said she would forfeit £10 to anyone who could prove that the instructions were not genuine. I cannot do it. I should be glad if you would inform me whether they are genuine in your opinion, as I should like to be able to claim the £10 offered if they are not. I certainly got a good photo from the one given with the instructions, but I think it must be a fake of some kind.—**DOUBTFUL.**

The instructions are quite genuine, but it is not an easy busi-

ness to remove a print from a mount so cleanly that it is used for the printing of a negative by contact. Still, the instructions are not dear at 2d.

**EXONIAN.**—If you will send your name and address we will reply.  
**STALE PLATES.**—I bought a lot of old large-sized plates (plate to 12 by 10) at a sale as a speculation for experiment with. Some of them are as old as 1890, some in unboxes, some opened but resealed. All are foggy, but some than others; some come out all patchy. Is there any resensitising them and making them fit for use? I have been renovating slightly exposed plates by soaking them minutes in a 5 per cent. solution of potassium bichromate. Would that be any use, or could they be reduced clean and then resensitised?—**P. G. PAYNE.**

The formula given in the "Almanac" on page 996 is used—viz., chromic acid, 30grs.; potass bromide, 60grs.; 10oz.—in which the plates are immersed for five minutes, dried, and dried. They will be slow in use.

**CLEANING MACHINES.**—I would be very much obliged to you could give me any idea of where machines for cleaning chalking glass for glazing P.O.P. might be obtained.—**W.**

We are not aware of such machines being used, but put a firm such as N. L. Scott and Co., 18, Ironmonger Lane could supply them.

**COPYRIGHT.**—If a customer copyrights a photograph and transfers the copyright to me, can I proceed against anyone making cards of it? I take a group, one man gives me orders, takes money, and pays me. I understand it is his copyright. I stop others using my photograph just taken.—**A. SECRETAN.**

Certainly you can if the assignment is in writing and a transference of the copyright registered.

**CHLORIDE OF GOLD.**—I inadvertently emptied a fifteen-grain bottle of dry chloride of gold into about a quarter of an ounce of a solution of cyanide of potassium. The same did not dissolve but a red precipitate. Can I do anything with the same?—**IGN.**

We presume you refer to sulphocyanide solution. The thing you can do is to pour the mixture into a hot solution of ammonia of about 150 grains of ammonium sulphocyanide, which probably you will get the gold precipitate to dissolve whole can then be diluted to a strength of two grains per pint, or whatever strength you employ for toning. It will pay you to use the gold in any other way.

**H. W. G.**—For plush materials, Strong and Co., Ltd., 8, L Street, City Road, E.C.; and Jas. Hy. Masters, Richbell Lamb's Conduit Street, W.C. For the shapes you might letley and Co., Soho Square, W.C., who can refer you to if they cannot supply you.

**WAKEFIELD.**—Messrs. Dawbarn and Ward, 6, Farringdon Avenue, E.C., can give you particulars.

**HANDYMAN.**—Impossible for us to say. Search at the Stationers' Hall, as required. This can be made on payment of a small fee.

**W. WASHAM.**—Your best plan is to rinse for a few seconds in a strong stream of water from the tap before immersing in tank.

**\* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received, to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

On the various important questions, such as proof of returns, absence of competition, the value of negatives, etc., which arise in the purchase of a photographic business are the subject of some notes page 382.

Dr. C. E. K. Mees and Mr. S. H. Wratten describe the construction of a wedge spectrograph permitting of much greater rapidity working in sensitometric tests of plates. (P. 384.)

Dr. E. J. Wall, in continuing a review of recent progress in colour-sensitising, discusses the fundamental law of Draper. (P. 386.)

Dr. Lüpke-Cramer, in the course of a comparison of the relative action of reducers, places the permanganate formula about midway between persulphate and Farmer's reducer as regards its "softening" action on the gradation of the negative. (P. 385.)

Dr. Hauberrisser has recorded the results of experiments made to obtain a bichromate sensitising solution which will give a carbon tissue of good keeping qualities under ordinary conditions. (P. 391.)

Patents of the week include a changing-box, enlarger, and "a device for photographing housebreakers whilst manipulating on the door lock." (P. 394.)

Mr. R. J. Wallace has published details of the apparatus employed by him in the daylight sensitometry of dry plates. (P. 388.)

Some peculiarities of intensification and toning with ferricyanide have been brought forward by a German worker. (P. 392.)

## EX CATHEDRA.

### The Reflex Camera Exhibition.

In addition to the names of firms whose instruments will be represented in the forthcoming exhibition of reflex cameras to be opened at the "B. J." offices on June 13, we have to add to the list given last week the name of

Houghtons Limited.

Our invitation to users of reflex cameras to co-operate with us in bringing together a collection of examples of the use of this form of camera has brought us a large number of responses, and, at the time of writing, there is every evidence before us that an exhibition of very considerable educational value to the hand-camera worker will be the result of our endeavours. We would say again that the latest date for prints to reach us is June 1. The prints may, of course, be either direct or enlarged.

\* \* \*

### Soap in Carbon Printing.

In most manuals on the carbon process, when directions and formulæ are given for making the tissue, soap is almost invariably mentioned as one of the regular ingredients, yet as a matter of fact soap is never used by the manufacturers of carbon tissue. It is, however, very useful in the development of the pictures. Everyone has found that when only a few prints have been developed in the same water, air-bubbles and froth are created, and soon become a nuisance. Although it is well known to old workers, it may be news to some that if a couple of fingers be rubbed on a piece of soap and the water then well agitated with them, the froth will at once disappear as if by magic; and, what is more, it will not form again, however much the water may be splashed about. When the developing water contains even quite an infinitesimal quantity of soap, there will be no trouble from froth, as the bubbles burst directly they are formed.

\* \* \*

### On Recording Experiences.

In an article in the Journal of the Society of Arts on "The Present State of Photography," Mr. Chapman Jones suggests that "Perhaps the most obvious and immediate need is the bringing together of the experiences of the everyday worker and the investigations and speculations of the investigators." Unfortunately, the everyday worker, not being a practised investigator, is seldom able to correctly describe his experiences. He misses important small details, and his particulars are so meagre that the investigator is bound to gather his own experiences by personal experiment. It then often happens that the experiences of the investigator and of the "everyday worker" differ seriously. We frequently see samples of

failures that are inexplicable. The perpetrator cannot describe how he obtained them, and the investigator cannot repeat them, so matters come to a deadlock. There is much to be learnt from failures, which may indeed rank as among the most important experiences of the photographer, but if photographers wish to have their failures explained, we suggest that they should, immediately after the event and while all details are fresh in the mind, sit down and write out as fully as possible all particulars, even those of the most trivial character. No detail remotely concerning the operation should be considered too insignificant to note down, and it is impossible to recall everything that should be noted if the memorandum is not made immediately. Similar care should be taken in all cases, whether failures are concerned or not, for the everyday worker's experiences of any kind are of little use to the investigator if they are not accurately and fully described.

\* \* \*

#### Cash at the Time of Sitting.

One may be pretty safe in speculating that photographers, next perhaps to medical practitioners, make more bad debts than most other businesses. This is very much due to a lax system that has gradually crept into the profession. At one time it was customary for sitters to pay for portraits at the time of sitting, and they came prepared to do so. A notice to that effect used to be displayed in the reception room, and when the sitter had decided on the size and style of the portrait selected, the receptionist made out a receipt, and the amount was at once paid. The receipt was then taken by the sitter to the studio, and shown to the operator, who saw from it the kind of picture desired. Sitters then looked upon prepayment as a matter of course, and no demur was made; but nowadays things are quite different, except, perhaps, in some of the third-rate establishments. The notices are still shown in some few high-class studios, but the conditions are rarely if ever enforced, or even put forward, and thus, as many know to their cost, there is frequently a great difficulty in obtaining payment. It is hard to say if there is a remedy for this state of things. If there is, it is in the concerted action of photographers as a body. This matter has more than once received the attention of the Professional Photographers' Association, but nothing practical has come of it, for when once a lax system obtains in any business, it is a very difficult matter to get matters right again. Still, some effort might possibly be successful by the combined action of the profession generally.

\* \* \*

#### Testing Shutter Speeds.

Herr Nairz, in "Photographische Rundschau," has recently proposed a method of shutter testing that is probably far in advance of any of the usual methods of ascertaining the simple duration of exposure. The method involves nothing but an exposure made with a rotating or moving camera on a naked arc lamp fed with an alternating current of known periodicity. The resulting image is a dotted or broken line, and by simply counting the dots or segments the time during which the shutter remained open can be ascertained with the greatest accuracy. This test, though not well known, is by no means new. We have at hand some test negatives made by identically this method some two years ago by Mr. William Short, of the L. and S.W. Railway Company, and since Mr. Short's experiments in this direction first came before us we have felt convinced that the method was a most satisfactory one. Unfortunately, everyone has not an alternating arc available, but those who have will find the test an extremely easy one to make.

#### The Astrographic Chart.

A somewhat disturbing note appeared in Monthly Notices by the Astronomer Royal and Messrs. Eddington and Davidson upon errors in the photographed réseau which was used in the measurements of the photographic plates of Eros, an intra-mercurial planet. It is disturbing, because we believe that all réseaux used for the astrographic chart are made by heavily silvering a sheet of glass, and then ruling fine lines at right angles to one another, so as to divide the plate into squares. After the plate has been exposed on the stars, a réseau is placed in contact with the film and a supplementary exposure given, so that the clear lines are also impressed on the sensitive salts. This naturally gives astronomers an easy and practical method of defining the position of any star, precisely as the lines of latitude and longitude enable us to find the position of any terrestrial city or place, when the latitude and longitude are given. An error in a réseau is therefore a very serious matter, and should it occur throughout the whole of those used by the various observatories engaged in the astrographic chart, it would mean a very serious amount of extra work in recalculating the positions of the stars which have already been catalogued.

#### POINTS FOR CONSIDERATION IN PURSUING A PHOTOGRAPHIC BUSINESS.

The man who is taking steps to acquire a business, photographic or otherwise, has need to be a sceptic in reference to all things which he cannot prove for himself. Although of the many reasons which are assigned for the disposal of a business some are actually the real ones, it is only natural to suppose that in a great many cases a business is sold because the proprietor cannot make it a sufficient source of profit. That is not to say that somebody else could not convert it into a highly remunerative concern, but the fact must be kept in mind by those who open negotiations with would-be vendors of businesses. Hence certain precautions should be observed, and although the precise nature of them varies with every particular instance, and although an item which is of the greatest importance may arise which cannot be considered in a general article, yet we will attempt to deal with a few of the matters which must be looked into before any definite offer is made.

First of all it is important to ascertain if the books have been properly kept—or if they have been kept at all—and if, on the former supposition, they show the returns and profits for the past three or four years. Unless there are good reasons to the contrary, it may be assumed that a decrease in the profits in the last year or two indicates that the business is on the down grade, and while a reason may be forthcoming from the owner which will explain the decrease, such as short time at a factory in the neighbourhood or dislocation of the thoroughfare for several months from the laying down of tram-lines, yet the ominous fact remains, and should be a caution to the buyer. If no regular books have been kept—and it is not infrequently the case that they have not—good proof should be required of the actual business done. To an extent the receipts for goods supplied to the proprietor should be some rough proof, but unless something of the kind is forthcoming it is wise to look upon the concern as a somewhat dubious one from a prospective purchaser's standpoint.

Bearing on the point of receipts, we may quote an instance from Mr. Bromley's excellent book, "How to buy a Business," published by Messrs. Fisher Unwin. The prospective buyer of a tailoring business, in examining the payment returns, found one entry from a certain customer to the amount of £40. Reference to the bank book showed that no cheque had been paid about that date, nor had a

amount been used in paying rent or some account. Nothing about the matter, but making a note of the customer's address, paid him a call, explaining that he had purchased Mr. X's business, and hoped for a success, etc., etc. The man was astonished. He had paid the cheque since he had discontinued his custom two years before the date of the entry. The intending purchaser went on congratulating himself that he had gone to the trouble of making for the cheque.

The only proof which can be given is that of the points for consideration are the class of business which has been carried on, and the expenses which the purchaser has had to incur. It will be manifest to most people that a small business which shows a return of, say, £100 a year, at high prices yields a much greater return than another with similar returns where the prices are low. For the cost of material in the former is less, and there is also less laid out for labour, in both respects the low price business is more expensive. If the business is of the club type it is carried on at a greater cost than the one just alluded to, inasmuch as canvassers' wages and commission have to come out of the proceeds, and there are also discounts to be allowed to the customers of the club type. A few comparisons of this kind will soon enlighten the purchaser as to the difference between businesses with the same gross takings, and it will not be forgotten also that in a cheaper class of trade the selling off of business means a good deal of anxiety for the proprietor from the fact of his greater current expenses. Another important point is the lease of the premises—its length and the terms upon which it is held. The state of the premises should be carefully inspected in conjunction with the terms of the lease, since one of the usual clauses in such documents relates to the premises being left in a state of thorough repair at the time of the expiration of the lease. For instance, if a purchaser takes over an old building which has only a year or two to run he may very possibly have to make good dilapidations which have been made since the lease was granted, and which would have been the subject of a substantial allowance from the price of the business. Neglect of this liability becomes a serious matter to a tenant, particularly if the building is old, and the lease has been a long one.

The usual course of the transfer of a business the vendors are bound over in penalty not to start or carry on another business of the same character within a certain radius, but this does not, of course, bind any of the employees of the business, or who may be as well known to the customers as he is, and it would also be well to ascertain what relatives of the vendor reside in the neighbourhood, since it is easy for a vendor to set a brother or sister up in business, and while this himself does not infringe the letter of an agreement he does so actually by his interest in and direction of another business. The same thing may occur in the case of a managing operator, the opening of a business by whom in the immediate neighbourhood might seriously affect the original one. The purchaser should ascertain beyond doubt the management of the business with this precaution in his mind.

It need hardly be said that the opposition in the locality to the possible increase which may occur should be carefully considered. Attention must be paid, too, to the locality of the work which the other places of business turn out.

Certain it is that if the newcomer who takes over a business which has been turning out fairly high-class work cannot maintain the same standard the patronage will assuredly leave him for his competitors. A keen appreciation is required here of one's own powers of production, or of one's ability to control the work of employees. Then again the character of the population requires to be very carefully considered. The prospective purchasers cannot be

recommended to adopt a better course than to remain in the district for a night or two during which time a little fraternisation with his hotel keeper will tell him more about the district than he might otherwise discover, or at any rate will put him in the way of investigating the facts for himself. In many cases it will be found that the district is in a transition state, and that, although there are many roads which have all the appearance of being occupied by well-to-do people, as a matter of fact the character of the place is changing from a better class to that of the working population. We could point out a number of London suburbs at the present moment which are undergoing a process such as this. A proper appreciation of such a change is, of course, of the highest importance to a photographer commencing business there.

These lines may come before some who, for the first time, are thinking of acquiring a business of professional photography. It behoves them to consider very critically their own qualifications for such a form of enterprise. We are constantly being approached by readers who have had a fair measure of success in portraiture which they have done at the request of their friends and acquaintances for certain good and valuable consideration, and therefore believe that there is a great future for them once they are installed in a regular studio. Let them consider that the photographer's is not an easy business. Apart from its calling for acute supervision of every stage of the work, it demands from the proprietor of a business more tact than those who have approached it from the amateur standpoint could believe to be the possession of mortal man. It is the easiest thing in the world for those who have never had any professional training to rush into a business for which, in certain important respects, they are totally unfitted, and then to find that the custom which they imagined would be theirs, has left their doors. In some cases such as this we have heard of legal proceedings being taken when a business has fallen short of an amateur purchaser's expectations. It should be borne in mind that in the photographic profession, as in the medical, a great deal depends upon the personality of the individual. If a newcomer be not so well liked as his predecessor, the clientele will, for no other reason, transfer itself to another establishment.

We may mention the importance which is frequently laid upon the large stock of negatives which have accumulated in a business. The value of a large number of negatives is very often fallacious. When negatives are more than a couple of years old orders for prints from them are usually very seldom obtained. The frequent changes in fashion has led to a more general practice of having fresh sittings in the latest attire rather than order copies from negatives which show the sitter in out-of-date costumes. The value of a stock of negatives should be estimated from by seeing, from the books, the amount of the orders which it has brought in the course of a year.

In dealing as we have done in the above remarks with the precautions which should be taken in the purchase of a business, we have, perforce, left out of consideration the very personal fact that the purchaser may be a more enterprising and better business man than the seller, qualifications which will usually take rank above the ability to produce high-class work in the management of a business. The existence of such capacity may frequently justify the acquirement of a business which is not doing well, yet contains the germs of a successful concern.

In conclusion, we can do better than refer again to the volume of Mr. A. W. B. Although it does not deal specially with photographic business, its forcible descriptions of the ways in which a purchaser may be "had" should be of use to any one who is about to enter on the responsibilities of proprietorship.

## THE WEDGE SPECTROGRAPH.

It has frequently been noticed by those who use spectrographs for recording the sensitiveness of plates, or the transmission of filters, that it is desirable to obtain a large number of exposures in juxtaposition upon the same plate. Thus, in their first paper (October, 1903) Newton and Bull used a series of exposures which varied from 1 to 100, getting what they termed a "practical" curve, and showing the maxima and minima of sensitiveness very clearly.

E. Belin has improved upon this method by rotating in front of the spectroscope slit a disc having a graduated opening, so that

Fig. 1.

different portions of the slit were exposed for different times, and the exposed plate gave a smooth curve forming, so to speak, a range of mountains, the summits of the mountains being the maxima of sensitiveness and the valleys the minima. This method can, with sufficiently accurate work, be adapted for purposes of measurement by using a disc, in which the opening should be cut in steps, either according to the type of the Hurter wheel or of the Scheiner sensitometer. In order

Fig. 2.

to accomplish this very accurate work is necessary in cutting the disc, and it is by no means easy to measure the resultant densities, which are necessarily of very small area. If in a one centimetre slit, for instance, nine sectors be taken (and a smaller number will scarcely suffice), then each sector will only be 1.1 mm. across.

For this reason it seems better for accurate sensitometric work to employ the method suggested by Sheppard and Mees ("Phot.

Journ.," March, 1906), and use the large sector wheel exposing instrument, having a spectroscope as part of the illuminating system. But for practical rapid work in laboratory this method of unequally illuminated slits offers advantages, because with a single exposure and without measurement a comparison can be made of the sensitiveness of different plates by simply observing the comparative heights of the maxima.

Small rotating sectors, however, are difficult to make accurately, and, like all instruments requiring rapid motion, are more or less clumsy in work, and it was clear that a better method would be to use a wedge of blackened glass with selective absorptions or transmissions.

There are three kinds of neutral tint glass which can be obtained. One has a strong transmission band in the middle, halving in density at this point compared with adjacent regions.

Fig. 4.

of the spectrum; the second has a strong transmission band in the deep red, and the other is distinctly violet in colour.

Fortunately, Messrs. A. Hilger and Co. were successful in obtaining for us a small quantity of glass which can be termed black, as the variation of its density throughout the spectrum is exceedingly small, as the following figures show:—

Wave Length.	Density.	Wave Length.	Density.
6,500	1.00	5,300	1.10
6,100	1.05	4,900	1.14
5,700	1.08	—	—

It will be noticed that not only is the variation small, but that it is regular, and therefore, showing no absorption or transmission bands, merely causes a slight modification of the intensity of the light employed with the instrument.

The first wedge prepared had densities ranging from

Fig. 3.

2.3, giving a range of exposure of from 1 to 128. But great as this may seem, it was found that in practice it was not sufficient for the range of exposure is not sufficient on the same plate to completely fill up the gap at one part, and yet give clear maxima at others, in the case of an erythrosine plate.

The second wedge prepared was made with densities varying from .2 to 4.2, giving a range of 1 to 10,000, and experience with this has shown that to utilise the largest portion of

the best range would be from 1 to 2,000. At the same time the second wedge was satisfactory, and as these accurately made glass wedges are not inexpensive, has been used. made by working to the same angle the black glass and piece of optical glass of the same refractive index, and joining them together with the apex of one opposite to the other, so that the formation of a refracting prism is avoided. The wedge is then fitted in front of the slit of the

Fig. 5.

scope in a small carrier of the type shown in the first which is convenient, as the wedge can be quickly moved out of position. The spectrograph used was the small instrument, with the opening at the back made much in order to include the whole image of the slit, and a glass giving in its horizontal direction the wave length, its vertical four lines representing 10, 100, 1,000 and times the unit of exposure. This is shown in Fig. 2. In addition to the black glass wedge there was also fitted to

this carrier a very small trough divided by a partition into two wedge-shaped compartments, so that if one of these be filled with the solution of a dye and the other with the solvent, a dye-wedge can be obtained and photographed in the same way as the black glass wedge shown in Fig. 3.

Fig. 4 shows the spectrum of a "Panchromatic" plate with a fully correcting screen. Spectra to acetylene light.

## THE ACTION OF REDUCERS.

(A paper in "Photographische Korrespondenz.")

I have already stated in an article in Eder's "Jahrbuch," 1906 (p. 237), that the characteristic action of the persulphate is explicable by the peculiar constitution of the negative emulsion. I then pointed out that previous explanations of the action, except that of a characteristic diffusion process, gave no satisfactory reason. Recently Dr. W. Scheffer\* in his interesting microscopic investigations on the action of reducers has confirmed my conclusions. Dr. Scheffer's microphotographs and graphic representation of the process are extremely instructive, and his explanation of the diffusion process appears very plausible. He reduced similar negatives with the two reducers to the same degree of transparency, and found that Farmer's reducer dissolved all the grains in the upper film, whilst the persulphate had reduced evenly the whole of the grains throughout the film. "From this," says Scheffer, "it follows that Farmer's reducer penetrates comparatively slowly into the film and slowly dissolves the grains, whilst the ammonium persulphate penetrates quickly and slowly dissolves the grains." I have concluded that these conclusions are not correct. As I have proved, silver consists of two substances, the one of more or less pure silver, the other a kind of compound of silver and silver chloride. The latter compound, which is yellow or light brown, is insoluble in nitric acid of a given strength, in chromic acid as well as in ammonium persulphate. It remains undissolved, therefore, even when the persulphate solution is allowed to act for some hours.

In consequence of this is that, even with continued reduction by persulphate, each grain leaves behind a light coloured residue which can be easily seen microscopically, as is correctly shown in Scheffer's drawing. As soon as a solvent for silver chloride, such as ammonium sulphocyanide, is added to the

persulphate, the latter acquires the power of dissolving the whole of the original grain of the negative, and its method of action is precisely the same as with Farmer's reducer. Since the latter, in consequence of the hypo in it, has no difficulty in dissolving the whole of the negative grain, and its reaction rapidity is greater than that of the persulphate, it dissolves the silver very quickly, but naturally it acts like every other solution, such as a developer, for instance, that is on the upper part of the film first. If thus, as Scheffer did, one reduces the density of the negative to the same degree of transparency with different reducers, the results must be as shown by Scheffer, without its being necessary to assume a difference in the diffusion process. At the same time neither potassium ferricyanide nor its mixture with hypo has any tanning action on gelatine.<sup>1</sup>

I have already pointed out in the above cited article that the action of persulphate cannot be ascribed to a specific action of the persulphate. Moreover, Andresen has confirmed a similar action with hydrogen peroxide, and nitric acid also reduces the highlights of a negative first. Further experiments have confirmed my view that any solvent of silver, if only a solvent for silver bromide is present, also acts in a somewhat similar, if not exactly similar, way to persulphate.

1. With chromic acid, 2 per cent. potassium bichromate solution with 1 cc. of strong sulphuric to 100 ccs., the action takes place very quickly, so that one cannot with certainty follow its course. A striking confirmation of this view is given by the addition of bromide or hydrochloric acid to the chromic acid solution, 1 gm. of potassium bromide or 3 ccs. of strong hydrochloric acid to 100 ccs. of chromic acid solution. The result is, then, not only

<sup>1</sup> A tanning action is often incorrectly ascribed to potassium ferricyanide. This has always been ascribed from the tanning action of mixtures of this with other salts, such as uranium, &c. Alone ferricyanide does not tan—Sedlacek has proved in his work on toning bromides.

a bromising or chlorising of the negative silver image, but a regular reduction. Sedlacek has recently observed the same thing, and has explained the phenomenon by stating that the conversion of the silver into silver oxide or the soluble silver sulphate into the silver halide. The high-lights (Warnerke's sensitometer was always used as a negative) are reduced by complete removal of the soluble silver, and consist then of the bright yellow bromide compound if the less dense parts still show absolutely intact silver. A subsequent fixation is not necessary with this kind of reduction.

2. Potassium permanaganate, 0.4 per cent. solution, 3-4 minutes; the manganese peroxide is removed by bathing in bisulphite solution and subsequent fixation. It cannot be observed direct on account of the managanese peroxide, yet there finally results a very "soft" negative—that is to say, the less dense numbers of the scale are still obtained, whilst the "lights" have become very thin. This action of the permanganate has been already observed by Namias<sup>2</sup>, and Eder<sup>3</sup> states that the action of permanganate stands about midway between that of persulphate and Farmer's reducer.

<sup>2</sup> Eder's "Jahrbuch," 1902, p. 124.

<sup>3</sup> Eder's "Handbuch," vol. III., 5th Edit., p. 557.

3. Cerium sulphate, 2 per cent. solution, with 2 ccs. concentrated sulphuric acid to every 100 ccs., acts almost the same as permanaganate, only the effect is easier to observe with cerium, because no reaction products hinder it.

4. Potassium ferricyanide, 10 per cent. solution—that substance which attacks the silver in Farmer's reducer, with the silver bromide solvent. It will often be observed clearly that first the densest parts of the scale are converted into ferrocyanide. After subsequent fixation "soft" scales result as in experiments 2 and 3, and this is very distinctly shown on parallel plates which have been reduced in a solution of cyanide and hypo.

5. Cupric chloride, 5 per cent. solution. The negative bleaches quickly, and is then fixed. In this case also considerably fewer negatives are obtained than with Farmer's reducer.

If the reduction process does not take place in experiments 2 to 5 in as striking a manner as with persulphate, hydrogen peroxide, nitric acid and the chlorising and bromising mixture in No. 1, they give a number of interesting series of intermediate results between the two principal types, the chief difference between them being the presence or absence of a silver bromide solvent which completely explains the differences in action.

DR. LÜPPO-CRAMER

## A REVIEW OF RECENT WORK IN COLOUR SENSITISING.

### II.

THE simplest way of arriving at some conclusive sketch is to give a summary of the theory that is generally accepted and then to examine it in detail. Arguing that the most likely theory is that advanced by him who has done the most work on the subject, one must necessarily come to Eder's work, and his statements are briefly as follows<sup>1</sup> :—

#### Past Sensitizers According to Eder.

1. The dye must stain the silver halide grain.
2. Dyes which vigorously sensitise are all so-called substantive dyes—that is to say, they colour substances direct, and probably by molecular attraction. Staining of the silver halide grain is no proof of colour-sensitising.
3. A dye sensitises for those rays which it absorbs, or, more correctly, for those rays which the dyed silver halide absorbs.
4. The maximum of sensitiveness lies at about the same position as the maximum absorption of the dye, with a general shift towards the red. More correctly stated, the maximum sensitiveness agrees with the maximum absorption of the dyed halide.
5. Dyes with narrow intense absorption bands generally give narrow intense sensitising bands, and those with broad ill-defined bands give broad ill-defined stretches of sensitiveness.
6. The brilliancy of colour of the dye has no special influence.
7. Neither the fugitive character of the dye nor its fluorescence have any action on the colour-sensitising properties.

#### Tests of Staining Action.

Proof of the first requirement is most clearly furnished by von Hübl's experiments.<sup>2</sup> Silver bromide, prepared with excess of bromide and copiously washed, was treated with eosine, cyanine, ethyl violet, and chinoline red, and the coloration produced observed. The dyed bromide was then treated with various solutions, and the results observed. The dyes were then used under similar conditions for sensitising collodion emulsion, were treated with the same solutions as the precipi-

tated bromide, and the sensitiveness measured. It must be understood that the sensitiveness observed applies solely to tests, for the test object was a photometer covered with a yellow and a blue filter, and the light employed magnesium ribbon, so that it cannot be compared with any other tests such as those of Eder or Mees and Sheppard.

Only one of von Hübl's results is given, that with ethyl violet :—

#### COLOUR OF THE SILVER BROMIDE.

1. Alcoholic solution of ethyl violet stains the silver bromide bluish-green.
2. Addition of water made the colour deeper and turned it more violet.
3. Ammonia removed the colour.
4. Potassium bromide removed the colour.
5. Sodium chloride only removed a little of the colour.

#### SENSITIVENESS RATIO V

1. The sensitised emulsion gave  $V = 6$ .
2. The plate bathed in water before exposure gave  $V = 1$ .
3. After the addition of ammonia the emulsion gave  $V = 1$ .
4. After a preliminary bath of bromide,  $V = 3$ .
5. After a preliminary bath of sodium chloride,  $V = 2$ .

Von Hübl says :—"The modern theory of dyeing gives a clear explanation of the staining power of the dye under the different conditions; this theory is that of solid bodies—that is, in the case, dyed silver bromide as 'solid solutions.' Alcoholic and aqueous solutions have different solvent powers for the dye, its condition of disassociation is different in the two solutions, and is thus influenced by various additions. On these conditions depends, then, the state of equilibrium between the dye and the two solvents—that is, the liquid and the silver bromide. Agreement with this law may be upset by chemical action or other phenomena. It is not permissible to ascribe the results obtainable with flocculent silver bromide to collodion or gelatin bromide emulsion, but the above results prove that the

(<sup>1</sup>) Summarised from "Die Grundlage der Photographie mit Gelatine-Emulsionen." Ausführliches Handbuch der Photographie. Vol. III. p. 150.

(<sup>2</sup>) Eder's "Jahrbuch," 1894 p. 189, and 1903 p. 128.

ose connection between the power of a dye to stain silver and its power to sensitise, as all circumstances which the staining also affect the sensitiveness."

#### Direct Action of the Dye.

second requirement is that the dye must be a substance, and colour the halide direct. This must be admitted, I think, and for the following reasons: A substance is one which is absorbed by a material direct from its without the intervention of any third substance, and from an adjective dye in that the latter requires a at or substance which combines with the dye-stuff to pro-staining. It is obvious that the use of a mordant would ce innumerable difficulties when dealing with substances itive to chemical action as the silver halides. Therefore, ordant is excluded, it would be obviously useless to use t those dyes which would stain direct—that is, substan-es.

#### The Effect of Silver Nitrate.

assumption, that the dye must be a substantive dye does clude the use of adjective dyes with substances which as mordants, and this may be an explanation of why a as silver nitrate in many cases acts better than the dye for the silver nitrate may act as the mordant, just in the ay as tannin or the salts of copper, tin, and aluminium al dyeing.

ust not be forgotten, however, that ammonio-nitrate of not only can increase the total sensitiveness of an emulsion e light, but, as proved by Eder,<sup>3</sup> actually increase the eness to the less refrangible end of the spectrum—that is, ers, or conduces to, colour-sensitiveness.

ould not be overlooked that in the use of silver nitrate ay be direct combination between the dye base and the as occurs in nearly every case with the phthaline dyes. of these silver dye compounds are insoluble in water, only insoluble in excess of silver nitrate,<sup>4</sup> but most ble in ammonia. One may, therefore, by bathing a plate lution of dye *plus* ammonia *plus* silver nitrate, introduce hich in itself is sensitive to light, and which may form cleus or germ for the latent image on the silver halide or ible image in metallic silver, and as, according to our heory, the light absorbed must act, it is obvious why we get colour-sensitiveness.

#### The Theory of Molecular Attraction.

a regard to the question of molecular attraction, one must ne or two hypotheses. Either there is direct chemical ation between the silver halides and the dyes, or there molecular or physical combination. This subject is ated by Eder.<sup>5</sup> Briefly, it is assumed that the vibrations sorbed by the coloured compound, and photo-chemical osition ensues.

ther the action be due to molecular attraction or chemical ation primarily, Kieser's researches, and those of Lüppor and Traube,<sup>6</sup> certainly point to some very close and te connection between the dye and the silver halides, as ater, when stained, can be repeatedly washed without re-of the last traces of dye. There is a "fixpunkt"—that is, ain stage beyond which no further dye can be removed by e: this proves either chemical combination or solid solu-and in the latter case beyond the "fixed point" the silver has a greater solvent action than water. This was also y Eder's classic experiment of forming an eosine-stained

emulsion, then washing repeatedly in a centrifugal separator till the washings were absolutely colourless, and still finding the characteristic absorption and sensitiveness of eosinated bromide of silver.<sup>7</sup>

It may be mentioned here that if silver bromide be precipitated in an aqueous solution of a dye, collected and washed till the fixed point is reached, further removal of the dye is at once rendered possible by treatment with gelatine solution. Further, as Eder proves (*loc. cit.*), it is impossible to remove the whole of the gelatine from the silver halides by repeated centrifugation and washing, 0.5 per cent. being tenaciously retained. One must take this into consideration, for the gelatine may act as a mordant for the halide.

#### Analogies from the Dyer's Practice.

Turning, on the other hand, to practical dyeing, one is met with the fact that it is possible to treat raw silk with a dye till deeply coloured, and then "strip" the silk, and the whole of the colour will be discharged and leave the silk fibre itself undyed. This "stripping" of the silk is the removal of the natural "silk gum," which is very closely allied to gelatine, if it is not gelatine itself. If the silk be stripped first, there is no difficulty in permanently dyeing the actual silk fibre. This fact may account for the failure of some dyes to act with a gelatine emulsion, whilst they will with collodion.

Against this we may place the fact that many vegetable fibres absolutely refuse to dye with certain colours, yet will at once do so if "animalised"—that is, treated with an animal substance such as albumen, or gelatine, or the like.

Points 3 and 4, dealing with the connection between absorptions or maxima of absorption and maxima of sensitiveness, may well be treated together, for they are very closely allied.

#### Draper's Law, the Basis of Orthochromatism.

The fundamental law underlying these statements is that enunciated by J. W. Draper—namely, "only those rays act chemically on a substance which are absorbed by the substance." If this law is correct, and I think that it will be seen to be, then it is obvious that what we must measure is the light absorbed by a light-sensitive compound.

I would lay particular stress upon this point, because it has been recently announced that there is distinct reciprocity between the maxima of a transmission spectrum and maxima of colour sensitiveness; in other words, that light which is not absorbed produces chemical action, which is in direct opposition to Draper's law.

This theory may be disposed of at once by a very simple argument. Let us assume that we have a solution of a dye which in a given strength and thickness of solution shows an *absorption band* extending from  $\lambda$  5,890 to  $\lambda$  5,590. If we examine this by an incandescent gas-light we shall see the whole of the visible spectrum with the exception of the above 300 wave lengths. What we see is the *transmission spectrum* of the dye solution; or, in other words, the spectrum of the incandescent gas *minus* 300 wave lengths. If now we place in front of the gaslight a naphthol green filter which absorbs all light of greater wave length than  $D_{\frac{1}{2}}C$ , or about  $\lambda$  6,220—that is, the extreme red—this and the above 300 wave lengths will be missing from the transmission spectrum. Again, if we proceed further and use burning magnesium ribbon as the illuminant, we shall find the three bright lines of that metal 5,183, 5,172, and 5,167 (which form practically the little *b* group in the solar spectrum) in the green, and close thereon a continuous spectrum starting from about  $\lambda$  5,007 to the violet end. The characteristic absorption of the dye is wanting, and the transmission spectrum is limited to the above light. If we push the argument still further and use a

Phot. Korr., 1885. Beiträge zur Photochemie. Part III. p. 13.

eworth. Phot. Quarterly. Vol. II. p. 197, et seq.

Beiträge zur Photochemie." Part III. p. 75. Original communication 1889. References are made to the "Beiträge" because this is a complete on of Eder's, Valentas, and other writers work on the subject, and being d together saves reference to different books.

B. J." 1907.

(7) "Beiträge zur Photochemie." Part III. p. 19.

Bunsen burner and thallium chloride, we find our transmission spectrum limited to one brilliant green line at  $\lambda$  5,350.

Obviously, then, in each case the transmission spectrum of the dye is the spectrum of the light source by which it was examined. If a plate be bathed with the above dye solution, however, the band of sensitiveness extends from, say, 6,120—5,890. In the face of these statements, which can be proved experimentally,

it is difficult to understand why the above theory should be advanced, or how it can be substantiated.

There is also one important fact which we must not overlook and that is, that whether we use colour-sensitive or ordinary plates, we obtain our image, not upon a solution of the dye upon dyed gelatine, but in all cases upon silver halides.

E. J. WALL, F.R.S.

## THE DAYLIGHT SENSITOMETRY OF PHOTOGRAPHIC PLATE AND A SUGGESTED STANDARD DISPERSION-PIECE.

### II.

#### Replica Grating Spectrograph.

THE form of spectrograph suggested for use with the replica has been modelled along lines somewhat similar to an instrument devised by Thorne-Baker,<sup>4</sup> but possesses several modifications. Its plan may be easily understood by reference to the drawing (Fig. 4). Simplicity combined with rigidity was the principal aim in the construction of the instrument. Lenses of greater focal length could be used for the formation of a longer spectrum without any difference ensuing save in the length of exposure time, but the dimensions

the C line ( $\lambda$  6563) in the centre of the plate. To enter here discussion of the resolving power of the instrument is unnecessary when we take into consideration the work for which it is intended. The spectrograph may, if furnished with slit and lenses of good quality, be used for a very high grade of spectroscopic work. A visual observation an eyepiece can be held by means of an adapter at the plane of the plate.

The spectrograph should occupy a definite permanent position in the laboratory, with the collimator pointing to the north.

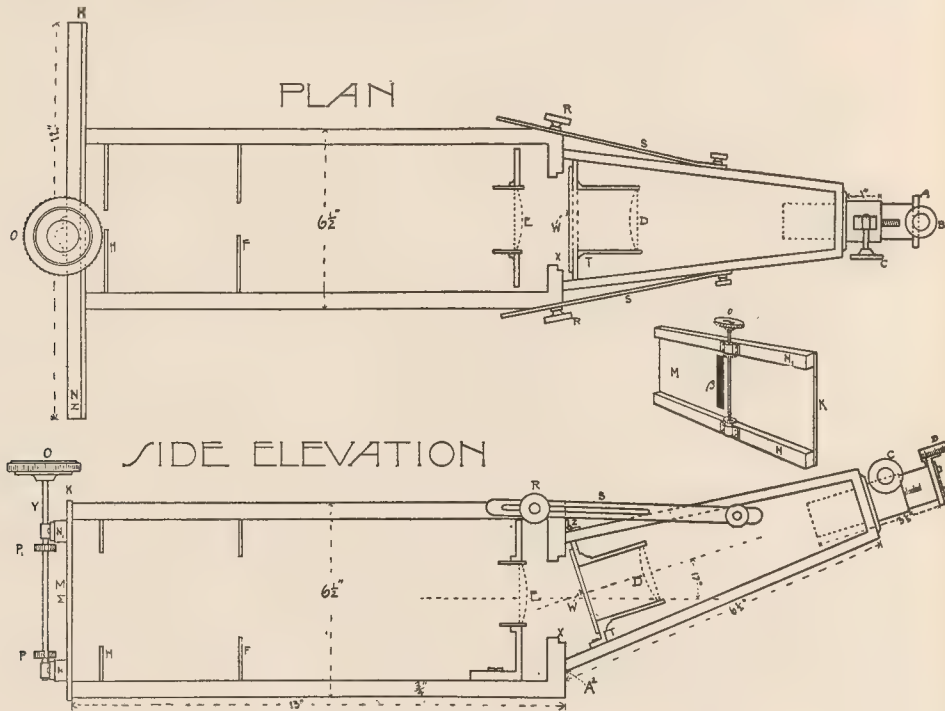

Fig. 4.

B, Aperture admitting spectrum to photographic plate.

of the instrument would thereby be increased. With the specifications given the spectrum measures 6.2 cm. from  $\lambda$  6900 to  $\lambda$  3550 (B-N), which is of good measurable length. For special examination of the red and infra-red end a narrow brass wedge-frame is inserted at A<sub>2</sub>, which changes the angle of the collimator and brings

always at the same angle. This latter point is provided for in the construction of the instrument. The width of the slit should remain constant, and all the light reaching it should pass through thin milk glass or other diffusing medium, free from selective absorption. Exposures for the determination of selective sensitiveness should not be made unless the altitude of the sun is greater than 15 deg. The length of exposure which constitutes the beginning

<sup>4</sup> "Journal Royal Photographic Society," 46, 161, 1906.

series varies with the speed of the plate—i.e. longer with "slow" than with a "fast" plate. In the case of the Seed plate (as indicative of fast plates) the exposures found most suitable are as follows: 2, 5, 15, 30, 60 seconds, 2, 4, 8 minutes; eight exposures, together with two others yet to be described, giving the entire  $3\frac{1}{4} \times 4\frac{1}{4}$  plate. With a "slow" plate the first exposures are omitted. Obviously it would not be advisable to expose so closely to those times when using sky light under extreme atmospheric conditions such as exceptionally bright on one day and raining on the next.

### Photometer.

It may be proper at this place to consider the instrument connected for the measurement of photographic densities. A very complete bibliography and discussion relative to photometry is contained in this class of work are given by Mees and Sheppard in their paper, "Sensitometric Investigations."<sup>5</sup> Following this, the author had constructed a Hüfner spectrophotometer; but after extending some considerable time with this form of instrument, he discarded in favour of a modified Brace prism instrument, as the former line dividing the two fields under comparison was very objectionable, and prevented a match of as high a degree of accuracy as if the shades actually adjoined one another.

Fig. 5.

Brace's original instrument<sup>6</sup> measurement of differing intensities was made by varying the slit-width on one of the collimators, readings taken being in terms of the screw-pitch (or slit-width), a numerical value of which may be obtained by interpolation upon a curve derived from a previous calibration by means of a rotating disk. In order to make the instrument more particularly suitable for the measurement of photographic plates, a number of modifications and additions were made, which will now be described. Immediately in front of, and in contact with, one of the collimators  $A$  (Fig 5), a Nicol prism  $N_1$  was mounted; while in line with that, and in line with its axis, a supplementary collimator  $B_1$  was carried by a rigid supporting-piece. Collimator  $B$  was also provided with a supplementary collimator  $B_1$ , the function of each being the delivery of a beam of parallel light to their respective slits.

The analysing Nicol  $N_2$  is carried in the telescope tube  $T$  (which can be lengthened in order that the rectangular diaphragm in front of the objective  $O$  might be in distinct focus). The angle of rotation of the analyser is read upon the graduated circle  $C$ . Between the two collimators  $A, B_1$ , two mirrors  $M, M_1$  are fed by a 30 c. p. incandescent lamp at  $L$ .

The plate whose opacity is to be measured is held in a special holder  $D$  between collimators  $B$  and  $B_1$ , where, by means of a sliding mechanism the differing opacities are brought successively into position in front of the bilateral slit.

A dispersion-piece employed is the now well-known Brace prism which is made up of two equal 30 deg. flint prisms of refractive

index 1.64822 for D, and carries on one of its inner surfaces a deposited silver strip 5 mm. in width, the two prisms being cemented together.<sup>7</sup> When first constructed, this cementing medium was alpha-bromonaphthalin, which possesses a refractive index very close to that of the glass used. Constant trouble was, however, experienced on account of the volatile nature of this medium and the difficulty of sealing it in, and eventually the prism was taken apart and recemented with Canada balsam. On account of the difference between the refractive index of the balsam and that of the glass, there is always present a small amount of reflected light; but as this light is proportional to the intensity of the incident light, it introduces no error in the readings worthy of any consideration, and is visible only when measuring very low densities.<sup>8</sup>

In adjusting the instrument for use, the prism table is raised until the beam from collimator  $B$  passes slowly below the centre of the prism, and the field presented when viewed through the observation tube  $T$  (which carries no eye-lens, being pierced only with a 2.5 mm. circular opening) is an illuminated rectangle, which is of even brightness throughout (A, Fig. 6), when all adjustments are made, and the light is equally intense from either collimator. Should one beam be possessed of greater intensity, the field will show two

Fig. 6.

squares of differing brightness (B, Fig. 6). This arrangement has been found more satisfactory in practice than that usually employed, viz., when the light enters the prism centrally and the field is shown crossed by the image of the silver strip, as in C, Fig. 6.<sup>9</sup>

When beginning a series of measures upon photographic plates, the slits on their respective collimators are first opened to approximately the same width, the greatest opacity in the plate to be measured is run into position, and a rough trial match is made, the object simply being the assurance of sufficient slit-width to give light enough for the lowest measure without running too close to the extinction point (zero). In practice it is not deemed advisable to read an opacity requiring a smaller mean angular measure than 2.0 deg. (=approximately 30 units of Hurter and Driffield).

The mirrors are carefully adjusted to reflect their light centrally through each collimator. Then, while the eye observes the interface of the prism through the telescope tube, and with the analyser set at 90 deg., slit  $S$  is altered slightly in width until an exact match is obtained between the two halves of the field, which is indicated by the absolute disappearance of the dividing line. From now on until the measurement of the plate is completed, neither slits, light, nor mirrors should be moved or altered.

The varying opacities are now slid successively into position in front of slit  $S_1$ , and the analyser rotated until a match with each is secured. As the zero of the analyser circle indicates the point of extinction, the formula for the expression of the luminous intensity is  $\sin^2 \theta$ , where  $\theta$  = the angle of the analyser, while the degree of blackening when represented in Hurter and Driffield density units =  $\Delta \log \sin^2$  from the "fog value."<sup>10</sup> In practice, readings made from both sides of the extinction point furnish a mean which eliminates any error due to the false position of the zero.

The methods of recording the measures obtained are shown in

<sup>7</sup> This prism was ground and polished by Mr. O. L. Petitdidier, of Chicago, to whom thanks are due for its optical excellence.

<sup>8</sup> Experiments are at present under way toward the adjustment of a balsam or non-volatile cementing medium of similar refractive index to the glass employed in the prism.

<sup>9</sup> It would probably serve the purpose better if the silver strip covered the entire lower (or upper) half of the interface. The beam of parallel light from the collimators could then pass centrally through the prism, and the single dividing line would fall in the centre of the field of view.

<sup>10</sup> A table was constructed giving the value of  $\log \sin^2$  from 0 to 90 deg. in tenths of a degree, thus permitting of rapid work.

Table I., which presents the density measurements of the lower half of plate No. 2, to be given in a succeeding table (Table 4 and Fig. 8).

TABLE I.

No.	ANGLE.		MEAN.	LOG SIN <sup>2</sup> .	$\Delta$ LOG SIN <sup>2</sup> . (= DENSITY).
	Above.	Below.			
Fog .....	76.5	72.8	74.3	9.9691	
1 .....	66.0	67.5	66.8	9.9263	0.0423
2 .....	55.0	54.5	55.3	9.8299	1.392
3 .....	42.0	43.5	42.8	9.6644	3.047

9 .....	9.9	12.3	11.4	8.6918	1.3773

As an example of the agreement in the measures of different observers a large number of settings were made by Messrs. Parkhurst and Jordan and the writer, upon the same opacities, A, B, the results of which are given in Table II.

TABLE II.

OBSERVER.	MEAN ANGULAR MEASURES.		LOG SIN <sup>2</sup> $\theta$ (= DENSITY.)	
	A	B	A	B
J .....	14° 05	9° 205	8.7874	8.4076
P .....	13° 33	9° 250	8.7642	8.4122
W .....	14° 05	9° 220	8.7874	8.4080

(Mean of 13 settings for each value).  
Probable error of average  $\pm$  .0003.

Difference: Density A = .0032.  
Density B = .0046.

It is well known that in visual photometry the position of the star relative to the comparison light exercises an influence upon the measures, and for this reason it was deemed advisable to test the match obtained in the spectro-photometer with reference to the vertical and horizontal positions. As it was not practical to arrange the instrument to show the two squares in a horizontal plane, all measures were made by alteration in the position of the observer. Professor Barnard and Mr. Parkhurst kindly made the necessary settings, and from a mean of ten in each position, for each observer,

Fig. 6a.

Spectrophotometer for Measurement of Photographic Opacities.  
(A. Natural Size).

the net result obtained was not above the error of observation. The instrument may therefore be regarded as free from error in this regard.

In using the instrument as a spectrometer, special fronts have been constructed for holding colour-cells, etc., while the records are made from readings on the divided circle X, which is carefully graduated on silver, and reads with two verniers direct to 20". The prism table is also graduated. Collimators A and B, together

with the observing telescope T, rotate around the optical centre of the instrument, and are furnished with clamping screws. T and B are also equipped with tangent slow-motion screws for delicate adjustments. It is, however, not advisable to disarrange the instrument when set up and adjusted for photometry, but to make instead of separate instruments for different lines of work. The aperture is 25 mm. with a focal length of 200 mm. Fig. 6a is from a photograph of the completed instrument.<sup>11</sup>

Another important point regarding this instrument is the arrangement to displace the two spectra horizontally relative to each other, so that the red of one spectrum is in juxtaposition with any hue in the other by movement of the single slow-motion screw shown in (Fig. 6a), while direct measurement may be made in any region of the matched spectra by movement of the slow-motion screw B.

The spectrophotometer as just described was constructed upon various lines of work requiring critical measurement, but such an instrument is by no means essential. The extremely simple and ingenious arrangement devised by Pfund<sup>12</sup> should be well adapted to meet all of the requirements in ordinary density measures.

### Influence of Light on Sensitometry.

The next point in order of importance is the nature of the light used for the determination of selective spectral sensitiveness. Upon this point there seems to be as great a diversity of opinion as there is in the spectroscopy employed. It is conceded by every hand that daylight is the illuminant par excellence, but the impossibility of obtaining such light constant in intensity and quality has led to the substitution of almost every known source of illumination.

If the question were one which concerned only the intensity of luminosity, the difficulties could be much more readily overcome. But unfortunately the distribution of spectral intensity is a variable potent factor. One has but to compare the spectra of the various sources, even roughly, to find that they present no agreement at all themselves. Some are deficient in the red rays, while others are deficient in the violet.

In the comparison of the acetylene flame (a), the spectrum was arranged with a Hübner-Albrecht rhomb immediately in front of and in contact with the slit-jaws. One of the rhomb surfaces was illuminated by a beam of diffused daylight, while the remaining surface received a beam from the diaphragmed acetylene flame. The distance of the burner from the slit was altered until the spectra appeared visually equal in the green. Exposures were then made upon a Cramer isochromatic plate for varying lengths of time, the daylight and acetylene spectra impressing themselves simultaneously.

In the comparison of the candle (b), benzine (c), and methyl alcohol (d) flames, and the incandescent electric light (e), the replica glass spectrograph was used without the rhomb, daylight exposures being made at the beginning and end of each series.

The great lack of ultra-violet in a, even with extreme exposure, is readily observed, together with the strong action in the yellow-green, which with a suitable plate would be shown extending with increasing action into the red. In d this effect is reversed, and the maximum action is shown to lie in the ultra-violet (as is also the case in the use of the electric arc-light); b and c are very similar to each other, and show the characteristic deficiency in the ultra-violet, with the corresponding increase at the red end.

Notwithstanding that this is a point to which many workers have directed attention, yet unfortunately in the majority of cases the same workers continue their use and publish spectral comparisons of plates made with the same light-source which they condemn for which they give no correction factor. It is obvious that the five selective sensitiveness of two plates determined by a light source different from daylight cannot furnish any reliable quantitative information regarding the true values of the plates, unless the arc-light be accurately calibrated in terms of daylight (by photographic means), and a formula derived from such calibration which may be used as a correction factor.

<sup>11</sup> Originally the photometer was a three-arm spectroscopic, constructed by Mr. of Chicago with his usual skill. The alterations necessary to convert it into its present form were made by the writer in the instrument shop of the observatory.

<sup>12</sup> "Johns Hopkins University Circular," 4, 20, 1906.

ports have been made to calibrate a light to the spectral value daylight, and though several approximations have been arrived at yet we are still far from a satisfactory conclusion. The latest best work in this direction is due to Mees and Sheppard,<sup>13</sup> who suggested as a standard, acetylene gas, burning under constant pressure, and with special care as to its purification, etc., to ensure constancy in the luminous intensity. This latter point presents no special difficulty. Inasmuch as the flame of acetylene gas is greatly deficient in the violet end of the spectrum, they devised a compensating colour-filter to correct this deficiency, whose action may be fully explained by stating that it was intended to absorb proportionately the excess from the least refrangible end of the spectrum. While this combination was undoubtedly an improvement, yet it was by no means satisfactory, and that this was recognised by these careful investigators themselves is proved by the introduction of

still another make of filter in a later publication.<sup>14</sup> This latter filter can, however, still be considered as no more than an approximation, which is, indeed, what these workers themselves term it.<sup>15</sup>

There are, however, numerous opportunities for the use of a standard artificial light, in which the difference in spectral distribution from daylight does not enter greatly into consideration, and for such the acetylene "standard" of Mees and Sheppard offers decided advantages. The writer has made use of a somewhat similar arrangement with most satisfactory and encouraging results.

The question now is: Does an approximation so arrived at offer any advantages over diffused daylight, if used under certain conditions, when applied to the determination of selective sensitiveness? Briefly, I hope to show that it does not.

## INCREASED KEEPING-POWER OF SENSITISED CARBON TISSUE.

(A Paper in "Photographische Korrespondenz.")

The older formulæ for carbon and the photo-mechanical processes, based on the light-sensitiveness of the chromates in combination with time and other organic substances, there will be found an almost edible chaos of views and receipts. Eder was the first to test these statements and clear up the chemical reactions in his classic book, "Ueber die Reaktionen der Chromsäure und der Chromate auf Atzalkalien, Gummi, Zucker."

Ever since the introduction of the carbon process experiments have been made to increase the keeping property of the sensitised tissue. The best process so far is the use of the calcium chloride box. Even in this the stability is limited and the calcium tube inconvenient, therefore I have tried other chromate compounds.

The salts hitherto used have been potassium bichromate  $K_2Cr_2O_7$ , ammonium bichromate  $NH_4_2Cr_2O_7$ , and ammonium chromate, also ammonium chromate  $(NH_4)_2CrO_4$ , potassium-ammonium chromate  $(NH_4)_2CrO_4$  and the sodio-ammonium chromate. As the chromates of the other metals are either insoluble in water or very slowly, I experimented with organic chromates.

I have been able to obtain a monochromate only by direct neutralisation of chromic acid with methylamine  $CH_3NH_2$ , the formula being  $CH_3NH_2H_2CrO_4$ . The solution is yellow and very similar to that of monochromate of ammonia. Tissue sensitised with this gave excellent prints, proved to be considerably more sensitive, and better than that sensitised with potassium bichromate.

Chromates of other organic bases were next tried. As by the direct method of preparation by the action of dilute solutions of chromic acid the bases, oxidation always occurred even at low temperatures, attempts were made to prepare the monochromates by the indirect action of calcium chromate on the sulphates of the bases. If a solution of calcium chromate is allowed to act on a solution of aniline sulphate, an almost insoluble calcium sulphate is precipitated and a yellow solution of aniline chromate is obtained.

In this experiment can only be performed with very careful work in the cold, and as the resultant solution of aniline chromate decomposes in a few minutes, whilst the colour turns a greenish black, aniline chromate cannot be used.

When this experiment proved valueless for practical work, I tried to make double salts of the monochromate of potash and the organic chromate.

Added to an aqueous solution of potassium bichromate enough ammonia to convert the red colour into a yellow, a solution of potassium-ammonium chromate is obtained, which in combination with gelatine is as sensitive as potassium bichromate, whilst the keeping properties of the tissue is considerably increased in hot weather.

The chemical reactions may be expressed by the following equation:—

If in this reaction the ammonia is replaced by organic bases, such as methylamine, oxamide, pyridine, pyrazol, carbamide, urethane, etc., and tissue be sensitised with the resultant solution, the prints will be as good as with potassium bichromate, neutralised with ammonia. Pyridine, which was added in alcoholic solution, and pyrazol were slowly oxidised in aqueous solutions. Bases such as aniline, naphthylamine, etc., which are easily oxidised, should not be used, as the solution immediately turns green.

The sensitiveness is somewhat increased with some of these new double salts, but not so much as to be of any practical value. After six weeks' wear all the tissue sensitised with these bases was absolutely insoluble in water.

As the addition of ammonia to the bichromate increases the keeping power of the sensitised tissue, a further increase of keeping was to be expected with an excess of ammonia. As the excess of ammonia evaporates in the dry tissue, some which had been sensitised with potassium bichromate and ammonia was dried and placed in a wide-mouth jar with a glass stopper. In the jar also was placed a small vessel, filled with ammonia, so that the tissue was in an atmosphere of ammonia. A second sheet of tissue was placed in a jar without ammonia, and both jars kept in the dark.

After six weeks the tissue which had been kept in the ammonia atmosphere gave a faultless print, whilst the other had become absolutely insoluble in hot water.

Attempts were then made to replace the ammonia by a non-volatile organic base, so as to avoid the inconvenience of having to keep it in glasses. The following experiments were tried:—

1. Stock solution, 100 ccs.;  $\alpha$ -naphthylamine, 1.94 gms.;
2. Stock solution, 100 ccs.;  $\beta$ -naphthylamine, 1.94 gms.;
3. Stock solution, 100 ccs.; pyrazol, 0.92 gms.;
4. Stock solution, 100 ccs.; aniline, 0.92 gms.;
5. Stock solution, 100 ccs.; methylamine, 0.41 gms.;
6. Stock solution, 100 ccs.; pyridine, 1.07 gms.;
7. Stock solution, 100 ccs.; m-phenylenediamine, 1.4 gms.;
8. Stock solution, 100 ccs.; p-phenylenediamine, 1.4 gms.

The stock solution was a 4 per cent. solution of potassium bichromate, with enough ammonia added to give a yellow colour.

The aniline, pyridine, the two naphthylamines, and phenylenediamines were dissolved in a little alcohol, and added to the chromate solution; a part of the  $\alpha$  and  $\beta$ -naphthylamine separated, and was filtered out. With the exception of the two last mixtures, all gave faultless prints; with m- and p-phenylenediamine there was a brown coloration in a very short time; tissue sensitised with these proved when dry to be absolutely insoluble in hot water.

The other sensitised tissues were cut in half; the one half gave perfect prints. The other half was kept in a black envelope in the dark. After six weeks all were insoluble in hot water.

Briefly, the results of these experiments, which are of considerable theoretical interest, are as follows:—

1. In place of the chromates hitherto used, monochromate of methylamine can be used, and the results are not inferior to those obtained when potassium bichromate is used.

2. Sensitised tissue will keep for a very long time in a solution in an atmosphere of ammonia.

3. Potassium bichromate can be neutralised with various organic bases, without the sensitiveness suffering.

4. The addition of non-volatile bases to carbon tissue, which has been sensitised with potassium-ammonium chromate, does not essentially increase the keeping power of the tissue.

GEORG HAUBERISSER

## INTENSIFYING AND TONING WITH FERRICYANIDE.

(A Paper in "Das Atelier des Photographen.")

IN his book on toning development papers,\* Dr. Sedlacek has considerably enriched our knowledge of the theory and practice of toning developed images by his thorough and scientific treatment of the subject. One statement therein, which is in opposition to preconceived notions, caused the author to experiment.

It has long been known and advanced by numerous writers that the uranium intensifier is by far the most satisfactory for negative work. This is not, as has often been stated, due to the reddish brown colour of the precipitate of uranium ferrocyanide, but to the fact that besides chemical substitution there is also a physical deposition of uranium ferrocyanide on the silver grain. This was first proved by von Hübl in his experiments on the uranium toning of platinum-types. He found that there was no substitution for the platinum, as by after treatment with ammonia the platinum was left in its original condition. There must, therefore, have been a physical intensification.

Kaiserling has observed microscopically, not only with platinum, but also with the silver grain, in which there was probably chemical substitution, an extraordinary enlargement of the original grain in consequence of the deposition round it of precipitated uranium ferrocyanide, and thus differentiating the process from other intensification methods.

E. Vogel has also pointed out that there was also physical as well as chemical intensification. Sedlacek assumed that in the process recommended by him there was no abnormal additional deposition, but only a substitution for the silver. Comparative experiments have proved to me that as a matter of fact there is an important difference between most of the older methods of toning or intensifying with uranium and Sedlacek's method. He first calls attention to the remarkable fact that in nearly all formulae for uranium toning equal quantities of uranium and ferricyanide are directed. This ratio, according to Sedlacek, is contrary to theory; "for one may correctly assume that in the reduction of a solution of uranium nitrate containing ferricyanide the normal uranyl ferrocyanide ( $\text{UO}_2$ )<sub>2</sub>  $\text{Fe}(\text{CN})_6$  is formed, therefore theory requires 1.5 molecules of uranium nitrate to 1.0 molecules of potassium ferricyanide, that is 756 to 329 parts—i.e., somewhat more than double the quantity."

A second important difference between the older toning formulae and Sedlacek's is that the former always contained an addition of glacial acetic acid, whilst Sedlacek forms a complex compound with organic salts, such as oxalates, citrates, tartrates, etc., which are then brought into an unstable condition of decomposition. These two conditions are important as regards the characteristic action of the baths.

If a negative is immersed in a solution of the old type *a* as follows—

Uranium nitrate, 10 per cent. solution.....	50 ccs.
Potassium ferricyanide, 10 per cent. solution.....	50 ccs.
Water .....	1,000 ccs.
Glacial acetic acid .....	50 ccs.

And another in Sedlacek's *b* as follows:—

Uranium nitrate, 10 per cent. solution.....	50 ccs.
Potassium ferricyanide, 10 per cent. solution.....	20 ccs.
Potassium oxalate, 10 per cent. solution.....	50 ccs.
Hydrochloric acid, 10 per cent. solution.....	10 ccs.
Water .....	1,000 ccs.

Several differences will be noticed. These are partly due to difference in tanning of the gelatine; but the chief differences noticed after the negatives are dried. The negatives treated with *a* show a considerable enlargement of the grain, and a roughness of the whole film, which those treated with *b* do not exhibit. Microscopic examination of the grain strikingly confirms the assumption that with *b* there is only chemical substitution, and that with *a* there is a physical deposition of uranium ferrocyanide round the grain.

As the uranium ferricyanide solution tans the gelatine to absolute insolubility, the thin films required for microscopic examination are best prepared by dissolving part of the unintensified film in water and coating very thinly on glass, and then intensifying these new films.

The accompanying illustrations show the difference very strikingly. Fig. 1 shows the grain structure after intensification in *a*, and Fig. 2 after intensification in *b*. The grain in Fig. 2 scarcely differs from that of the unintensified negative, whilst in Fig. 1 the gross deposition of the uranium ferrocyanide scarcely permits of the original grain being seen.

Further experiments showed that the difference in action of the

Fig. 1.

Fig. 2.

above solutions cannot be ascribed only to the oxalate in *b*, but also to the great excess of ferricyanide in *a*, for if in this only 20 ccs. instead of 50 be used the physical deposition of uranium ferrocyanide takes place only to a limited extent.

There is a marked difference in the behaviour of the two baths. Solution *a* is brown and decomposes even after one or two hours standing; whilst *b* is a pure yellow and remains clear for a long time. The difference is not in the addition of the oxalate, but also in the increased proportion of ferricyanide in *a*. The spontaneous decomposition of the uranium ferricyanide in a 5 per cent. solution is completed much more quickly with an excess of potassium ferricyanide, and especially if the solution is warmed.

By the introduction of the oxalate complex and the exact equivalent quantities, as used in Sedlacek's formula, there is produced a purely chemical substitution, whilst in the old type of intensifier there is physical intensification, the result of the ready spontaneous decomposition of the solution by the catalytic action of the silver of the negative, an action which increases with the instability of the solution and the time it is used.

The addition of organic salts to regulate the action of ferricyanide toning baths has been repeatedly recommended. Srna used

\* "B. J.," August 10, 17, 1906, pp. 624, 645.

ammonium oxalate for iron blue toning; Namias also used ferric oxalate. For toning with copper ferricyanide, which is insoluble, Namias has used the soluble complex compounds with oxalates or citrates; Ferguson, Eder, and Clerc used potassium citrate for the same purpose. We are indebted to Sedlacek for a systematic investigation of the action of these salts.

The addition of sulphocyanides has great influence on toning with ferricyanides. It was first observed by Namias that ammonium sulphocyanide in the uranium toning bath for bromides hastened the process and gave better results. Payne was the first to state that platinum prints could be toned with uranium. Strakosch used ammonium sulphocyanide for this with success, and the action was more closely studied by von Hübl. He found that ammonium sulphocyanide in the uranium bath acted as a reducer, and that it could be replaced by other salts, such as sodium sulphite, thiosinamine, and even grape sugar. In the iron blue toning process sulphocyanides were used with success by von Hübl, and this aquation was also used for copper toning platinotypes by Menke, and for uranium toning bromides by Welborne Piper, and with iron salts by Eggli.

The strong action of sulphocyanides in the uranium toning baths can be directly observed. Even in the cold after a short time the aquation of uranium ferrocyanide begins. If sulphocyanide is added to the mixture of iron alum and potassium ferricyanide, there appears first of all the intense blood-red coloration of ferric ferrocyanide, which turns slowly into a smutty green, and then a pure Berlin blue.

It was also obtained with the iron blue toning and Sedlacek's formula that a physical intensification of the silver grain, which is easily seen under the microscope.

From the above facts it is obvious that for very vigorous intensification the old solution without oxalate and with equal quantities of ferricyanide and uranium salts is more suitable; whilst for mere intensification of bromide prints Sedlacek's formula is preferable.

DR. LÜPPO-CRAMER.

#### COPPER TONING.

DR. R. NAMIAS, writing in the current number of the "Photographische Korrespondenz," refers to the liability of the red and brown tones given by the copper ferricyanide process to darken after a time. This change is due to the fact that the silver ferrocyanide, when with long immersion, is not completely converted into copper ferrocyanide. If this conversion could be more effectually carried out a quantity of the red compound and the intensity of this colour would be increased.

Dr. Namias finds that this can be attained by immersing the toned print in a solution of

Copper sulphate .....	1 oz.	50 gms.
Salt .....	90 grs.	20 gms.
Water .....	20 ozs.	1000 ccs.
Pure hydrochloric acid .....	50 min.	10 gms.

this bath the silver ferrocyanide is converted into silver chloride, and copper ferrocyanide is formed, which increases the red colour of the print. This is attained in a few minutes, in five at the most.

The prints must be well rinsed in water, and then dipped into a 5 per cent. solution of hypo, containing 5 per cent. of boric acid. In this the silver chloride dissolves. The prints obtained by this process are of much more brilliant red than those obtained with the ordinary nitrate bath.

The tone obtained is very beautiful and useful for many subjects, particularly portraits. As it is important to know that prints, even when exposed for some time to direct sunlight, will not change, a print obtained in this way was half covered with black paper and exposed to intense sunlight. It showed not the least difference between the covered and uncovered parts.

For blue toning, Dr. Namias prefers the use of two baths, the one a 5 per cent. solution of potassium ferricyanide, with 5 per cent. ammonia added, and the other a 1 per cent. solution of ferric chloride, containing 2 per cent. of hydrochloric acid. Only in this way can an intensely blue picture be obtained. After toning the silver chloride

can be removed with hypo. If the copper toning is carried out in this latter way very weak prints are obtained.

## Photo-Mechanical Notes.

### Cleaning the Metzograph Screen.

One of the best ways to clean a metzograph screen on the grained surface, writes Mr. S. Scholes in the "Questions and Answers" Department of Messrs. Penrose's "Process Work," is to take a small bottle of methylated spirit and add a little piece of iodine just to discolour it. A small frame should be used like an inner frame of a dark slide, to keep the screen from touching the bench, the screen is placed in this, and a small amount of the methylated spirit and iodine shaken out of the bottle (which should have a spirit cork) and carefully rubbed over with a small piece of wash leather until it evaporates dry. Now take another small bottle only containing methylated spirit, and rub over again, using a full size wash-leather, and this should be rubbed as quickly as possible; this should be done now and again, while the screen is in use, but if the screen is in continual use it is advisable to clean it each night with a strong solution of potassium cyanide and iodine, with cotton wool, rinsing well under the tap and putting aside until the morning, when it should be cleaned again with methylated spirit and a large wash leather. When not in use it should be put away in an air-tight grooved box without anything touching it on either side. This box should be attached to two strong brackets and put on the wall or in the fireproof safe.

### The Bolt Court Report.

The report of the eleventh session of the London County School of Photo-Engraving and Lithography, which Mr. A. J. Newton and his assistant, Mr. A. J. Bull, have so successfully directed, speaks highly for the quality and the range of the instruction provided at the old City mansion at the end of Bolt Court, Fleet Street, E.C. The report records continued progress in the number of students—565, compared with 488 in the tenth session—and it is satisfactory to find that process firms are constantly applying to Bolt Court to recruit their staffs. We are glad to see, also, that the research side of the school's activity—an important feature of its work—has been strengthened by the completion of several pieces of investigation of value to students as well as to the process trades.

The graphic contents of the report include all the current processes of illustration, and almost all instances are reproductions of originals by students in the art or the "process" school.

### Combined Line and Half-Tone.

According to the recent patent specification (No. 11,975, 1906) of Dr. Edward Mertens, 36, Jäger Strasse, Grosslichterfelde-ost, Germany, a method of obtaining line and half-tone negatives (from an original in which both occur) on the one negative is as follows:—Two or more copies of the model or original are drawn printed, or applied in any other suitable way in a light colour to a black, red, yellow, green, or other non-actinic ground or a ground covered with a mixture of the colours, so that one or more of such copies constitutes a whole-tone component or components of the original and one or more of such copies constitutes a half-tone component or components of the original respectively. Upon the same light-sensitive plate, film, or paper these components are then photographed in succession; first the whole-tone component or components without a screen, and then the half-tone component or components with an interposed screen, or the operation may be effected in the reverse order.

### PHOTO-MECHANICAL PATENTS.

The following Patents have been applied for:—

PHOTOGRAPHS.—No. 6,497. Improvements in the means of making photographs for photo-engraving and similar purposes. Ignaz Herbst and Franz Spalth, 1, Great James Street, Bedford Row, London, W.C.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between May 6 and May 11:—

**FILMS.**—No. 10,472. Improvements in photographic films. John Edward Thornton, Altrincham, Cheshire.

**FILMS.**—No. 11,054. Improved automatic film exposure checker for photographic cameras. Alfred William Bennett and Charles Colthurst Holland, 21, Great St. Helen's, London.

**DEVELOPING CLOCKS.**—No. 10,538. Improvements in developing clocks for photographic and the like purposes. George Lindsay Johnson, 7, Southampton Buildings, London.

**COLOUR PHOTOGRAPHY.**—No. 10,611. Improvements in methods of, and apparatus for, reproducing pictures or photographs in natural colours. Burton Stearns Philbrook, 8, Quality Court, Chancery Lane, London.

**CAMERA ATTACHMENTS.**—No. 10,695. Improvements in attachments for use with photographic cameras. Ernest George Brown, 30, Belvoir Street, Leicester.

**CINEMATOGRAPHS.**—No. 10,716. Improvements in cameras and apparatus for photographing and exhibiting cinematograph, mutoscopic, and ordinary pictures. Henry William Hamblin Palmer, 43, St. Martin's Lane, Charing Cross, London.

**COLOUR PHOTOGRAPHY.**—No. 10,717. Improvements in direct one-plate natural colour photography. Henry William Hamblin Palmer, 43, St. Martin's Lane, Charing Cross, London.

**COLOUR PHOTOGRAPHY.**—No. 10,718. Improvements in three-colour photography and the projection in natural colours upon a screen in animation. Henry William Hamblin Palmer, 43, St. Martin's Lane, Charing Cross, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**IMPROVEMENTS IN PHOTOGRAPHIC CHANGE-BOXES.**—No. 13,351, 1906. This invention relates to an improved photographic change-box adapted to be charged and emptied in daylight. For this purpose the box, which is provided with a closable charging-aperture, contains an internal rigid frame which is so arranged as to laterally enclose the pile of plates and is provided at the end, adjacent to the charging-aperture, with an aperture for the passage of the pile of the plates, and at the other end with certain slots for the passage of the exposed plate when it is withdrawn by the change-slide and reinserted at the back of the pile.

The invention is illustrated in the annexed drawing, which is a longitudinal section.

At the front part of the change-slide abutments are provided, the purpose of which is to remove the uppermost plate each time the slide is withdrawn from the box. The plate withdrawn by this means assumes the position indicated by dotted lines, and then the position indicated by full lines. The back of the slide is provided with projections, against which the plate withdrawn abuts. Two springs arranged within the slide serve to press the withdrawn plate against the back of the said slide. The rigid internal frame which constitutes the principal novelty of this change-box comprises a part adjacent to the discharging-aperture of the box, and is provided with apertures for the passage of the projections already referred to, and is so formed as to leave slots through which the foremost exposed plate may pass out, and be again inserted behind the pile.

The manner in which the change-box is used is as follows:—

The end of the case is inserted into the aperture of the empty change-box so that a light-proof joint is made between the two receptacles by means of the guides. The slide-shutters are thereupon withdrawn, and also the abutment-slide. The change-box is then held in such a position that the plates slide by gravity from the case into the box. When the plates have

entered the change-box the slide-shutters are closed and the box is ready for use. The plates are changed by successively withdrawing and re-inserting the change-slide, so that plates are

successively removed from the front of the pile and conveyed to the back thereof. The emptying of the change-box is effected in a manner analogous to the charging. The word "plates" used herein is intended to cover any form of sensitised layer carrier whether of glass, celluloid, or otherwise. Optische Anstalt C. P. Goetz, Aktiengesellschaft, of 44/46, Rheinstrasse, Friedenau near Berlin.

**AUTOMATIC DEVICE FOR PHOTOGRAPHING HOUSEBREAKERS WHILE MANIPULATING ON THE DOOR-LOCK.**—No. 3,345, 1907. This invention relates to an automatic device for photographing housebreakers whilst manipulating on the door-lock.

In the keyhole of the door a bolt is arranged and provided with two differently sized transverse holes. The bolt is passed through a gaspipe, or through a block inserted in said gas pipe so as to tightly fit said block.

Above the keyhole an opening for taking the photograph therethrough, and again above the same another opening for the illumination of the outside of the door by flashlight, are arranged.

Above the photographic apparatus, which is mounted on the door behind the opening, a cup is arranged which is filled with the flashlight powder. Into this cup the gaspipe is led with its upper orifice, whilst the lower end of the same is connected with a gas supply pipe, which is preferably effected by means of a rubber pipe.

When now an instrument, or the like, is introduced into the keyhole by the burglar, the bolt is pressed back, whereby the lever system is actuated in such a manner as to turn the closing plate away from the openings and thus freeing the latter, whilst the larger hole of the bolt is caused to coincide with the bore of the gaspipe, thus allowing a larger quantity of gas passing therethrough, so that a larger flame is produced in the cup which ignited the flashlight powder. By these means, a photograph of the burglar standing outside the door is taken. Hubert Wessling, of 319, Promenade, Borken in Westphalia, Germany.

**IMPROVEMENT IN CINEMATOGRAPHIC APPARATUS.**—No. 9,370, 1907. This invention relates to portable apparatus for photographing, exhibiting animated scenes, of the kind wherein the photographs are taken upon circular discs that are adapted to be rotated intermittently by mechanism giving a step-by-step motion, so that successive portions of the discs are brought in order in front of the lens or viewing aperture in the outer casing of the apparatus, the exposure or viewing interval being controlled by a revolving shutter.

Each sensitive plate is placed in a closed casing having a shutter whereby the plate can be protected from light when not in use of the apparatus, the shutter being manipulated when the casing is in place in the apparatus to uncover the plate at the position where the photographs are to be taken. Henri Louis Huet, 114, Rue du Temple, Paris.

**IMPROVEMENTS IN PHOTOGRAPHIC ENLARGING APPARATUS.**—No. 15,111, 1906. This invention has for its object a means for strengthening and simplifying the construction of daylight enlargers.

It is well known that the said enlargers generally consist of a light-proof tapered casing, provided with a means for holding the negative and the enlarging lens at the smaller end, and the sensitive material on which the enlargement is made at the larger end.

The method hitherto commonly in use has been to form the said casing either of wood or cardboard, the latter being usually covered with a suitable fabric for the purpose of rendering the joints light proof and giving the apparatus a suitable finish.

The objection to the use of wood for the above purpose is that the shrinkage to which it is liable has a detrimental effect

the focus of the enlarger, and the cost of manufacture is considerable.

With cardboard or similar material the objection arises more particularly from the instability of the joints and the difficulty and cost of construction.

According to our improved system we adopt a combination

Fig. 1.

of cardboard sides which are glued or otherwise fixed into grooved corner beadings, as will be clearly shown in the accompanying drawings, in which Fig. 1 is a perspective view of the complete apparatus with a part of one side removed to show the lens board and fillets. Fig. 2 is an enlarged sectional detail showing the formation of the grooved corner beadings and the

Fig. 2.

manner in which the cardboard sides are fixed therein. Herbert Holmes, Photographic Apparatus Manufacturer, Tudor Works, Tudor Road, Hackney, London, and Houghtons Limited, Photographic Manufacturers and Dealers, 88 and 89, High Holborn, London, W.C.

**IMPROVEMENTS IN PHOTOGRAPHIC PRINTING APPARATUS.**—No. 16,390, 1906. The object of this invention is to make photo prints, such as ferro prussiate, ferro gallic, etc., from engineering or other tracings, in continuous lengths, which is accomplished in the following manner. The machine is made after the form of an ordinary roller mangle, one of the rollers being hollow and made of glass, of any convenient length, to suit the width of paper used, arranged on each side and close to the glass roller. Two or more other rollers of the same length, made of wood or other suitable material, are placed around these wooden or other rollers, and a continuous band of cloth or other material, so that it presses on about half the circumference of the glass roller, which is geared by mitre wheel or chain to one or more of the wooden rollers. It will be seen that when the rollers are revolved the glass roller and endless band will travel in opposite directions, and both the tracing and the photo printing paper passed between them will be gripped, and carried evenly through. Inside the glass roller, which is open at both ends, are placed several electric mercury vapour tubes, or other high candle-power electric vacuum lights. James Warry Vickers, Finsbury Square Buildings, London, E.C.

**IMPROVEMENTS IN TELEMETERS OR DISTANCE FINDERS FOR PHOTOGRAPHERS AND OTHERS.**—No. 12,512, 1906. This invention relates to a telemeter designed to ascertain the distance at which an object to be photographed is situated from the observer, so that, the distance being correctly known, the camera may be focussed and the exposure made. It consists of a sighting tube combined with, or in a fixed relative position to the centre of suspension of, a plumb weight. When the sighting tube is horizontal the plumb weight hangs at right angles and vertical to it. The sighting tube is directed to the base or ground line of the object to be photographed, and as the weight will hang

perfectly vertical it will give the angle formed between the line of sight and a perpendicular line drawn from the eye of the observer to the ground. This angle, by means of suitable gearing, is multiplied and converted into a circular motion and conveyed to a pointer moving over a dial, which, instead of being marked in degrees, is, for the sake of convenience, marked off to show the distances in feet or metres, so that the distances may be read off with the greatest ease.

This instrument can also be used to level the camera, as when the pointer is pointing to an arrow head marked on the dial the

sighting tube of the telemeter is at right angles to the weight and is consequently in a perfectly horizontal line.

This instrument is for use on level ground, and hence should the base or ground line of the object to be photographed stand higher or lower than the ground on which the observer is placed, the necessary allowance must be made for this difference of level by directing the sighting tube to a distance higher or lower than the object which would be level with the ground on which the observer stands.

The instrument may be fixed to the camera or independent thereof, and it comprises a case closed at front by a glass cover and containing the weight which is suspended by a spindle which works freely in bearings in front and rear plates or supports in such manner that whatever may be the vertical position of the telemeter the weight will, within predetermined limits, always hang vertical. Only a certain amount of angular movement of the plumb weight is necessary, and it is then stopped by striking against the case. The instrument may be in the form of a watch carried in the pocket. Frank William Riches (Engineer), of 11, Toutschkoff Pereoulk, St. Petersburg, Russia.

## New Trade Name:

**PUSHAKE.**—No. 291,795. Chemical substance included in Class 1, and not included in other classes. Fuerst Brothers, 17, Philpot Lane, London, E.C., merchants. April 3, 1907.

**MR. T. NAYLOR**, manufacturer of photographic apparatus, etc. (late of Halway Street Works, Tottenham Court Road), intimates change of address to 24, Denmark Street, Charing Cross Road, where in future he will trade under partnership title of Naylor and Luck.

**THE ROYAL SOCIETY.**—At a conversazione held at the society's rooms, Burlington House, on May 8, one of the most interesting exhibits was that shown by Dr. F. D. Chattaway, F.R.S., of copper mirrors deposited upon glass from aqueous solution. Although silver is very readily deposited upon glass in this way and extensively used in the manufacture of mirrors, it has hitherto been found impossible thus to deposit the metal copper, but the mirrors exhibited proved equal in brilliancy and uniformity of surface to those treated with silver, and, on account of the colour of the copper, much more beautiful.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### A Pictorial Object Lesson.

THE most satisfactory method of dealing with pictorial work on an outing (says a writer in "The Photographic News") would be for the leader to select some subject which appealed to him, to get his standpoint and expose his plate. Then let each member carefully examine the subject, see how much of it was included on the ground glass, and, if possible, hear in a few words what the leader proposed to do in the way of treatment. Then, at a club evening, a straight print might be shown from the negative, either contact or enlarged to the size it was proposed to make the picture. A second similar print might also be shown, with any alterations in the way of lightening or darkening which might be intended, these modifications being made with charcoal grey and Chinese white, applied with a brush. If club facilities existed, the enlarged negative making, with the necessary control, might form another demonstration.

### Oil Pigment Printing.

In speaking of the actual pigmenting in his oil printing process Mr. G. E. H. Rawlins (writing in "The Amateur Photographer") says: "At this point we reach the most important part of the proceedings, for it is in the application of the pigment that the process becomes plastic, and the picture evolves as we may command it. The pigment of which it will consist is a very carefully adjusted oil paint, quite different from the variety used by painters, and in order to apply it a small quantity (about the size of a match-head) must be carefully spread, *very thinly*, on a piece of glass, and one of the special brushes lightly charged by gently dabbing upon it. On applying this to the blank print some of the pigment will be transferred, and the picture will begin to appear. Gently it comes, the shadows drawing to themselves each its proportion of the colour; but one perhaps comes forward too much, showing brighter than the impression the scene itself left upon the mind. A little extra pigment on the brush, a persuasive touch, and down it goes to the exact value we desire. Or, again, the negative gives us a tame, sad passage where we saw all light and silvery—a quick turn of the brush, a sort of flicking action, and it shines out full of brilliance. In fact, whatever effect we feel to be desirable is readily within the reach of a mere modification in the handling or manipulation of the brush."

### Exposure for Architectural Subjects.

With regard to the exposure of architectural subjects, Mr. E. R. Bull (writing in "Focus") gives the following advice: "For interiors the only reliable guide is that of experience. Notes should be made of the precise conditions at the time of each exposure, and the results so gained will act as a guide for future practice. As the characters of the subject and lightings vary to such a very great extent, only a rough estimate can be quoted. In the light portions of the cathedrals, as the naves, in a good diffused summer light, and the lens working at  $f/22$  on rapid plates, from three to five minutes will be required. If stalls or other dark objects be included the exposures must be increased, and here orthochromatic plates will be found advantageous. In very dark parts, as crypts, the exposures often run into several hours. It is well to remember that in this class of work, under-exposure renders the plate useless, and the exposure should be for the shadows; the high-lights will take care of themselves. When exposures are of prolonged duration, persons passing in front of the camera may be ignored, providing they are constantly on the move. But should they remain in one place or sit down, the lens should be capped. This may occur many times during one exposure. Light coloured clothing is particularly apt to produce ghosts, and thus spoil the picture."

MESSRS. RILEY BROS. (late of 55 and 57, Godwin Street) have removed to more extensive premises at 17, Colonnade, Westgate, Bradford, where all communications should now be addressed.

SEASONABLE ADVERTISING.—A good example of window advertisement is to be seen at the present time at the Kodak Company's branch, 40, Strand, where a realistic seaside view of children playing on the beach is depicted, one of the number being occupied in kodaking his companions.

## New Books.

"Lehrbuch der Microphotographie." By Dr. R. Neuhauss. Published by S. Hirzel, Leipzig.

It is nine years since the second edition of this text-book was published, and considerable advances have been made during that time, not only in the construction of micro-objectives, but also in the preparation of plates.

A brief historical survey of photomicrography, which is, we venture to assert, the correct term, opens the book, and this deals rather with the evolution of apparatus from Mayer's simple instrument of 1844 to the latest complete installations of Zeiss, Reichert, and Leitz.

The objective, the effect of immersion fluids, and projection oculi are dealt with in very simple fashion, a remark which may also apply to the chromatic difference of focus and the production of monochromatic light filters. The sources of light are treated more fully, and there is here much valuable information, based on the only satisfactory foundations of spectral composition, plate sensitiveness, and resolving power. The condenser and its use comes in for like simple treatment.

The particular arrangements for dark ground, side or polarised, stereoscopic work are somewhat more fully treated, but those spectroscopic work are meagre.

The section devoted to photographic manipulation pure and simple is commendably brief; commendable in that the author assumes that either the worker is acquainted with photography or that he will have access to purely photographic text-books, therefore the instructions given deal rather with the particular modifications incident to the special work in hand.

The concluding sections dealing with "the importance of photomicrography" and the methods of reproduction are particularly happy; we have here a sketch of the value of the work and the value of every reproduction process.

As a manual for photomicrographic practice, we can warmly recommend Dr. Neuhauss' work, particularly to those who are acquainted with the general practice of photography. It is well illustrated throughout by diagrams, and at the end some fine half-tone cuts of type and photogravure illustrations are given, amongst which would specially mention those of some Zenker laminae, that is, laminae of interferential colour work, and one of the well-known *Amphipleura pellucida*.

"Elektrische Fernphotographie." By Dr. Arthur Korn. 2nd Edition.

This booklet is an extension of the first edition, necessitated by the important practical advances which Dr. Korn made during the past two years in his method of reproducing pictures electrically at long distances. It gives an interesting historical review of previous attempts in a similar direction, and describes in full the author's carrier forms of transmitting apparatus. The principal change taken place in the receiver, the high tension vacuum discharge tube with its attendant complications, having been replaced by a much simpler though delicate arrangement, which, owing to its small inertia, permits of higher speeds in transmission.

The receiver consists now essentially of an "Einthoven Galvanometer," in which a very fine wire is stretched between the poles of a powerful magnet, this wire "sagging" under the influence of the currents traversing it. A small shutter attached to the wire is thus made to more or less stop out the rays from a source of light, and thus to introduce the variations in depth of printing which result in the print.

A most important addition is the "Selenium Compensator," a theory of which is developed. Its principal function in this case is to eliminate some of the time "lag" of the Selenium, and render possible speed of transmission greater.

The method which Dr. Korn has evolved undoubtedly shows some very practical and satisfactory results, and should, during the next few months, become familiar to the general public, owing to its having been acquired by one of the great London papers.

"Résumé des Travaux Publiés." Par MM. A. and L. Lumière, Lyons.

This is an extremely useful collection of brief summaries of all the published papers by the authors on photographic and other subjects dating from 1877 to 1906. In all cases the original source is given, and therefore it is possible to turn this up if it be thought necessary.

M. Lumière's investigation work, most of which has been reported on our pages, has touched on most photographic subjects, and it could be found very handy to have in one volume a summary of the same.

## New Materials.

Wellington Canvas Bromide. Manufactured by Wellington and Ward, Elstree, Herts.

This is a distinct novelty which should find considerable favour, both for contact printing and enlarging. It is a real canvas paper, giving well the grain, and is therefore specially suitable for artistic effects. It is very strong, and will therefore stand considerable rough handling if required.

It is quite sufficient for us to say that it is coated with the well-known Wellington bromide emulsion, and is manipulated in exactly the same way as any ordinary bromide paper, and is obtained at the same price.

This new material will be warmly welcomed by the enthusiast in enlarging, who can with it obtain a fine canvas grain effect without use of bolting silk or other media.

"Shash," a universal concentrated single solution developer. Sold by Fuerst Bros., 17, Philpot Lane, E.C.

Details will be found elsewhere of a competition which has been instituted by Fuerst Bros., with prizes amounting in all to £150 for its obtained with this developer.

From our trials with this developer, which may be obtained either in solution or cartridge form, it is possible to obtain excellent negatives. It is adjustable to various exposures by mere dilution with water and the addition of bromide, and is also suitable for development papers. It is clean working and not very readily oxidised, so it answers to all the requirements of the practical worker.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, MAY 24.

Leen Photo Art Club. Indoor Meeting.

SATURDAY, MAY 25.

Camera Club. Outing to Knaresborough.

Middlesex Photographic Society. "Record" Outing.

County Photographic Club. Outing to Allesley and District.

East and District Photographic Society. Outing to Mitcham.

East Park and District Photographic Society. Outing to Old Park, Winchmore Hill.

MONDAY, MAY 27.

East Photographic Society. Outing to Esholt.

East and District Photographic Society. "Gum Bichromate." W. F. Slater.

East and District Photographic Society. "Essential Qualities of Photographic Apparatus." G. Kimber.

East and District Photographic Society. Pictorial Competition.

East and District Photographic Society. "Theory and Practice of Time Development." W. F. Slater.

TUESDAY, MAY 28.

Photographic Society. Technical Meeting. "A Measurement of the Efficiency of Dark-Room Filters." C. E. Kenneth Mees, D.Sc., F.C.S., and K. Baker.

Photographic Society. "Camera Adjustments." A. J. Hyder.

Photographic Society. "Intensification and Reduction." A. E. Bawtree.

Photographic Society. "Copying." J. Leadbeater.

Photographic Society. Social Evening.

WEDNESDAY, MAY 29.

Photographic Club. "Sepia Platinotypes." Demonstrated. W. A. Hooker.

Photographic Society. "Lantern Slides." R. J. G. Owen.

Photographic Society. "Theory and Practice of Self-Toning Papers." John Griffin & Sons.

Middlesex Photographic Society. Technical Meeting.

THURSDAY, MAY 30.

London Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

FRIDAY, MAY 31.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

Photographic Society. "The 1906 Outings." E. H. Ingleton and L. T. Jones.

a series of capital negatives, some being on plates over a year old and kept under adverse conditions. The greater part of the evening was devoted to an explanation by the authors of the pictures, of the conditions under which their respective negatives were exposed and developed, and to a consideration as to how the various plates (mainly orthochromatic, behind filters) translated the original scenes.

## Commercial & Legal Intelligence.

A "WANTED" PHOTOGRAPHER. — Sergeant Whaley arrested at Consett an itinerant photographer, William Stephenson, alias Clark, who is said to be "wanted" at Welshpool.

ALLEGED ADVERTISEMENT FRAUD.—The opening scene in an important police prosecution was enacted at the Liverpool Police Court, when Thomas and William M'Hugh, father and son, were charged in several cases with having obtained money by false pretences and with conspiring to defraud. Thomas A. Anderton, a young ship's steward, stated how he replied to an advertisement in a Liverpool newspaper, and received a letter inviting him to call at a certain photographic studio. He did so, and saw William M'Hugh, who informed him that he wanted a steady, reliable young man, that his father was financing the business, and was a retired solicitor and a member of the City Council, which fact obtained him Corporation work to the amount of £100 a week. He (William M'Hugh) had also a studio in the Isle of Man, and wanted witness to manage the Liverpool branch. He asked for a premium, and £30 was eventually paid over to William M'Hugh. The evidence in other cases was almost identical, and accused were remanded.

A CANVASSEER CHARGED.—At the North Holland (Boston) Petty Sessions last week William Westoby, 56, photographer, Alford, was charged with obtaining money by trick. Walter Morley, machine owner, Wigtoft, said prisoner called on him on January 18, and solicited orders for photographs. He agreed to have his machine photographed, and paid prisoner 5s. for three copies. On March 1 prisoner called again, and said the photograph had come out badly. He therefore took another photograph, and witness gave him another 5s. for three more copies, none of which he had received. Evidence was given showing that prisoner also obtained 8s. from Mrs. Poole, wife of a cottager, at Sutterton; 5s. from John James Alexander, farmer, of Gosberton Fen; 10s. from Walter Alexander, labourer, at Gosberton Clough. Mrs. Eliza Ann, Gosberton Clough, said prisoner lodged with her from March 4 to 15, and left owing her 8s. 6d. Prisoner gave his address as East End, Alford, and Mrs. Lucy Raithby, of that address, said prisoner had lodged with her, but left in February, owing her 30s. Prisoner said he would execute the orders he had received if the magistrates would grant him time. He admitted that in December, 1903, he was committed to prison for one month at Grantham for obtaining money by false pretences. He was committed for two months' hard labour.

CHEAP PHOTOGRAPHY.—In the Lynn County Court Charles Holman, 30, Norfolk Street, Lynn, tobacconist, brought an action against George Mason and C. Foster, formerly trading as the Gainsborough Photo Company, but now as the Stickybacks Company, 59A, St. Matthew's, Ipswich, photographers, to recover £5 for damages done to premises. Judgment for defendants.

A FOLKESTONE BANKRUPT.—On May 9, in the case of Leonard John Watson, photographer, Folkestone and Canterbury, the liabilities were put at £248 10s. 10d.; net assets, £64 1s. 1d.; deficiency, £184 9s. 9d. Debtor said he started business about seven years ago at Folkestone as a photographer. He had about £25 capital, which he had saved whilst an assistant. The business was a success. Last October he opened a branch business at 6A, The Parade, Canterbury, because the doctor said his wife could not live in Folkestone. The business in Folkestone, which he left in charge of an assistant, then went down very considerably. Debtor, continuing, said the rent he paid at Canterbury was £90.

The Official Receiver: What was the reason of your giving up 6A, The Parade?

When I found I could not square up things properly at Folkestone I thought the best thing to do would be to tell Mr. Philpot, the landlord, to get another tenant.

In answer to the Official Receiver, debtor said he sold the Folkestone

ROYDON CAMERA CLUB.—A number of prints of excellent average type were on the walls last week, representing the work done by members on a recent excursion. A medal offered for the best picture awarded Mr. H. P. C. Harpur by ballot amongst those present. Harpur had been giving panchromatic plates a trial, and showed

business just before the receiving order for £20, and £4 was deducted for expenses. He left the furniture at Canterbury as security. He gave instructions subsequently to Messrs. Young and Briggs (and signed a document to that effect) to sell the furniture, and the proceeds were to go to pay Mr. Philpot for rent, and the balance to be paid over to him (debtor).

The Official Receiver: The effects were not sold at the date of the receiving order?—No, Sir.

The Registrar: Where were they?—In Messrs. Young and Briggs' custody.

The Official Receiver: Did the whole of these things belong to you?—Yes, Sir.

The Official Receiver: Did you give Mr. Philpot any reason to believe that you could pay your debt in full?—No, Sir.

In answer to the Registrar, the debtor said he had an interview with the landlord, and he said that if debtor gave him some security the goods which were then at The Parade would not be stopped. It was agreed at his (debtor's) suggestion that the landlord should be paid out of the proceeds of the sale.

Did Messrs. Young and Briggs render you an account?—No, Sir.

The Official Receiver: I claimed the effects.

The Registrar: Are you to have an account?

The Official Receiver: Oh, yes

Mr. Mercer (who represented Mr. Philpot) said, in courtesy, at all events, the Official Receiver should have an account.

The examination was adjourned until June 6.

#### NEW COMPANIES.

BARKAS AND COMPANY, LTD.—Registered May 1. Capital £200, in £1 shares. Objects: To carry on the business of chemists, druggists, drysalters, oil and colourmen, dealers in photographic, surgical, and scientific apparatus and materials, etc. No initial public issue. Registered without articles of association. Registered office, 54, Franciscan Road, Tooting, S.W.

## Correspondence.

*\*\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

*\*\* We do not undertake responsibility for the opinions expressed by our correspondents.*

#### A WAVE OF ORTHOCHROMATISM.

To the Editors.

Gentlemen,—I would crave permission, as a user of orthochromatic plates in my photographic work, which is employed by me merely to obtain records of pleasing arrangements of masses and light and shade, to suggest that the artist and the artist alone is the real judge of the value of an orthochromatic plate. The scientific worker is totally misled by the bogey of "luminosity values," which are not required in pictorial work. It is on this point, I think, that your clever correspondent, Mr. E. A. Salt, has wrecked himself.

We artists, and I use this term because it is as an artist of the paint-brush I write, do not want correct luminosity values. We want contrasts in colour, a subject of which the average photographer is woefully ignorant, and probably through his education—that is, the continued use of ordinary plates—is very loth to admit, or is unable to see.

Correct luminosity values I have found useless, but I have found a very great improvement in the use of colour sensitive plates, both with and without a filter. In taking a subject, however, I invariably note what the particular colour contrasts are that I want to accentuate, and choose my filter accordingly. This necessitates the use of three or four filters, and it is not always necessary to use them.

Mr. Salt's contention that "orthochromatism" is a reserve force and a reserve force only I deny. There is a marked improvement in the early and late seasons of the year in the rendering of the colour values on a colour sensitive plate without a filter; but it requires the trained eye that is trained in colour sense (not photography) to see

the same. It is here that I venture to suggest that your esteemed correspondent fails. He judges his results from the monochrome photographic standpoint, and not from that of the polychrome art.

I enclose my card, and remain, yours faithfully,

S. Kensington.

A COLOUR PAINTER.

To the Editors.

Gentlemen,—I feel grateful to "Professional" for having recognised, in his temperately written letter, that I recommended ortho plates for certain subjects. To satisfactorily render distant views, skies, and objects at close quarters presenting heavy colour contrasts, ortho plates and filters appear to be indispensable. In the case of distant views, a loss of atmosphere no doubt sometimes occurs, this may possibly be due to the filter used cutting too sharply. I am also glad to note that he also touches upon the desirability of plates for certain classes of work. Their finer grain, and, generally speaking, greater latitude, in exposure are certainly points in their favour.

Mr. Ernest Human appears to have undertaken the rôle of "Glorious" to your editorial remarks, but with variations. In these is not particularly happy. Opening in the best "penny plain, t'pence coloured" style, he melodramatically expresses his astonishment that the views I advanced should be possible in 1907. Now this is not my argument, nor is it particularly polite. He next cites a remark as to the "subtle difference," and goes on to say, "True, difference of tone value, and tone value alone." Of course, Mr. Human does not mean to admit the difference is "subtle." Not he; it is of his little way of expressing himself.

I also think that Mr. Human is mixing up "tone values" with "correct luminosity representation of colours in monochrome." Though related to each other they are essentially different. Give a panchromatic plate, an adjusted filter, a subject within the latitude of the plate, and correct exposure, then the relative luminosity values of the coloured original no doubt are secured. The resulting negative, however, may be quite incapable of rendering true tone values by any known printing process. How difficult these are to secure an expert picture copyist knows full well, even with the original before him for comparison. Here also the question is complicated by the fact that occasionally colour luminosities must be falsified to apparent truth, or, in other words, suggestion of colour contrast in monochrome.

In reference to Mr. Human's question as to "usual standards" am not aware that anyone has ever suggested that the capacity of an ordinary plate, under certain strictly limited conditions, to render blue as white, and red as black, should be considered "standard," and I see no use in the invention of futile suppositions as a basis of discussion. This is, however, significant of the attitude often adopted by violent partisans of orthochromatism, who arrogantly cannot appreciate the added power it places in their hands without unduly depreciating an old and tried friend, which has done magnificent work in the past, and is capable of repeating it in the future.—Yours faithfully,

E. A. Salt.

#### FOCUS OF NEGATIVE LENS.

To the Editors.

Gentlemen,—With reference to the query, "B.J.," p. 359, I beg to offer the following rule:—

To measure the focus of telephoto negative lens:

Let  $I^1$  = image diameter formed by positive lens.

$I^2$  = image diameter, of same object, formed by telephoto negative lens, combination without altering the position of the positive lens ( $I^1$ ).

$M$  = magnification.

$E$  = camera extension = distance from concave surface of negative lens to the nodal point, if known, of negative lens to screen ( $I^2$ ).

$N$  = negative focus.

$$\text{Then } \frac{I^2}{I^1} = M, \text{ and } \frac{E}{M-1} = N.$$

Yours truly,

Bishop Auckland, May 21.

H.

# Answers to Correspondents.

matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay. Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered less the names and addresses of the writers are given. Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., Wellington Street, Strand, London, W.C. For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. No unmounted copies of each photograph must be sent with the

LE HALF-TONE INKS.—Could you inform me if it is possible to use any of the sympathetic inks into a condition for printing in half-tone blocks. I want the printing to be invisible if warmed or otherwise treated.—PUZZLED.

Within our knowledge it cannot be done, since the action of pathetic inks depends on the absorption of water, a process which cannot go on in a greasy ink.

ING.—In enlarging from a negative which has matt varnish on the back, I cannot prevent the outline of varnish from showing on the bromide print. I have tried using piece of ground glass next the negative, but though that is an improvement, it is not by any means obliterate the outline. I use artificial light to enlarge by.—ENLARGER.

is not possible to avoid this unless the image is thrown slightly out of focus or a lens with a large aperture used, and image only focussed for. This means very exact focussing, the slightest error will at once throw the back of the glass out of sharp focus.

RO LENS.—Can you inform me where I am wrong? I have been trying to calculate a telephoto lens for a special purpose to use from 10in. to 20in. focus, but am at a loss to ascertain the I want. In Lummer's book on this subject he gives as multiply focus of positive by focus of negative, and divide difference less separation. Now, taking as positive lens of focus and a negative of 6in. mounted  $\frac{1}{2}$ in. apart gives the wing:  $8 \times 6 = 48$ ;  $8 - 6 = 4\frac{1}{2}$  = what? as  $8 - 6 = 2$  and will not go. What will be the focus obtainable by combining a 6in. and 8in. lens and mounting them from 3in. to 4in.—PUZZLED.

the case in point the calculation is  $8 \times 6 = 48$ , and  $4\frac{1}{2} = -2\frac{1}{2}$ , therefore  $-48 \div -2\frac{1}{2} = +191.5$ in., which is a five focus. The error lies in the omission of the minus sign. rule to find the focus of any supplementary lens is as stated Lummer, and it is obvious the decrease of the distance of separation in above calculation will considerably increase resultant positive focus; thus if the distance of separation reduced to 4in., the positive focus is 24in.

OUNTANT.—I have been using the dextrine mountant on p. 994 of the "Almanac," but although I have used was supplied to me as the best dextrine, it will not set. is the cause of the trouble?—MOUNTER.

re is no doubt that the dextrine is at fault. The formula ers perfectly if the best white dextrine is used. The only to do is to obtain two or three samples and submit them practical test, following the formula exactly.

G PRINTS.—A friend has shown me some line drawings

which he said were made from prints, but he was unable to give me any more information than that the actual prints were used. Can you tell me how this is done, please?—H. V. ESDALE.

The prints, which can be bromide, or P.O.P., or any silver process, are outlined with special waterproof ink, which can be obtained from almost all dealers, and then the silver image is dissolved, either with

Thiocarbamide .....	240 grs.
Nitric acid .....	$\frac{1}{2}$ ozs.
Water .....	20 ozs.
or Iodine .....	$\frac{1}{2}$ grs.
Potassium iodide .....	30 grs.
Potassium cyanide .....	30 grs.
Water .....	5 ozs.

The first is preferable, as it is not so poisonous as the latter. The print soon disappears in this, leaving the ink lines.

PANCHROMATIC FLASHLIGHT.—Is it possible to add any salts to magnesium powder so as to obtain a flashlight suitable for copying water-colours, etc., as I find the ordinary mixture does not give the orange and red well.—MAGNESITE.

Strontium, calcium, and lithium salts may be added, and thus red and orange rays be obtained, in addition to the green, blue, and violet of the plain magnesium. It would be far better to obtain one of the commercial panchromatic mixtures, which burn rather slowly and thus enable one to give sufficient exposure. An ordinary flashlight would hardly be sufficient, especially if colour filters were used.

LEARNING THE BUSINESS.—I am an artist, successful portrait and landscape painter, but not sufficiently certain of employment to marry. Therefore, I should like to take up photography as a profession, relying on art only as yielding additional income. I have some knowledge of photography as an amateur, but, of course, want to learn it properly before taking over a small business. 1. Are there situations where I could get experience and knowledge, at the same time rather earning than paying a premium? 2. How long do you think I should have to learn?—F. K.

1. The best thing to do would be to look through the small advertisements of situations vacant or else advertise in our columns for a situation. On the other hand, it would be possible to obtain instruction at one of the schools. 2. This entirely depends upon your present knowledge, but six or twelve months should be enough.

DIRECT SEPIA BROMIDES.—Is it possible to obtain by any commercially practicable method direct sepia bromides—that is, by development alone?—POSTCARD.

The following method has been recommended, using the following developer:—

A. Pyro .....	30 grs.
Metol .....	60 grs.
Sodium sulphite .....	1 oz.
Potass. bromide .....	30 grs.
Water .....	20 ozs.
B. Sodium carbonate .....	3 ozs.
Sodium sulphite .....	$\frac{1}{2}$ oz.
Water .....	20 ozs.

If mixed in equal parts with normal exposure a warm black is obtained. By increasing exposure one-half and using 1oz. of A, 1oz. of B, and 2oz. of water, a warmer tone is obtained. With three times normal exposure, and using 16oz. of water and 30 minims of 10 per cent. bromide, a bronze sepia is obtained. By merely increasing exposure and the amount of water and bromide, great variation in colour is obtainable. Whether this is commercially practicable is another question; we should have thought that either the sulphide or hypo-alum toning methods, which are both commercially used, would have sufficed.

COPYRIGHT.—Will you kindly tell me to whom does the copyright belong when a free sitting is given?—N. T.

The following extract from the "British Journal Photographic Almanac" for 1906 answers your question. The rights of the photographer in regard to the use of the negative are very different when he receives no good or valuable consideration for taking the photograph. Clause 1 of the Act then vests the copyright in him. The question of what is valuable consideration was mentioned in the case of "Ellis v. Marshall," which is an instance of the free or invitation sitting. Miss Mary

Moore, the actress, sat for her portrait on the invitation of Mr. Ellis, paying him nothing, though she received a few courtesy copies, and the copyright was ruled to be the property of the photographer. It has been argued that the subsequent sale of copies to the sitter constitutes valuable consideration, but such is evidently not consistent with the Act, which is clear in stating that "the negative shall be made or executed for a good and valuable consideration." In the very usual case of the reservation of the copyright to the photographer when he received a consideration, the statute is equally clear in requiring a written agreement at or before the time of sitting. This agreement should state the consideration (reduced price, etc.) which the photographer is to give for allowing him to reserve the copyright, and it should be stamped with a 6d. agreement stamp. A copyright is property, and, legally, a transfer of property involves a consideration. A customer, for a consideration to the photographer, acquires the copyright in his photograph; for a consideration from the photographer, which may be much less than that to the photographer (a discount from the usual price, for instance), he allows the photographer to reserve the copyright; practically he transfers it to the photographer.

**COPYRIGHT.**—I have a negative (not copyright) of a client who paid for photos at time of sitting. I am now anxious to get assignment of copyright, and he is willing to assign. What steps must I take? Must he copyright first and then assign to me, or can he just assign by filling in copyright form and me then registering? Please explain, as I have never seen the point explained. Thanking you in anticipation.—**COPYRIGHT.**

All that is required is a written memorandum, which must be appended to the ordinary registration form, which sets forth the fact that the owner of the copyright assigns the same to you.

**CANVASSING.**—I go round from door to door photographing groups at their apartments, submitting proofs, etc. Do I require to have a licence? I have been told that I do.—**CANVASSER.**

We have heard the same statement made, but in our opinion no licence is needed.

**BROMIDE TONING.**—Can you tell me how to tone bromide postcards to a purplish brown, such as one sees on the commercial cards.—**PRO.**

The method adopted in some cases is that of the hypo-alum bath, which will, when ripe, give this particular colour. The formula, as given in our "Almanac," is quite satisfactory, and is as follows:—

Hot water .....	20 ozs.
Hypo .....	2½ ozs.
Dissolve and add:	
Alum .....	½ oz.

This solution should not be filtered, as it works better as it becomes older; it may be strengthened from time to time with a little fresh solution. The best results are obtained by keeping the bath hot, or as warm as the emulsion will stand, say, 100 to 120 degrees Fahr. The prints will tone in from thirty to forty minutes. Much quicker toning and more purple tones are obtained by adding to the above bath—

Silver nitrate ..... 10 grs.

When the bath begins to take too long, throw half of it away and add fresh solution.

**ACID FIXING BATH.**—An acid fixing bath for use with bromide paper is very frequently recommended. Is this essential, and what are its advantages? So far I have not used it, and have not met with any special trouble.—**H. E. T.**

The acid fixing bath immediately arrests development, and prevents any chance of stain from oxidation of the developer. If in your practice you can turn out good work without it, there is no necessity to alter your method of working.

**GLAZING PRINTS.**—I have repeatedly tried to glaze P.O.P. prints by squeegeeing to glass, ferrotype, and celluloid, but in all cases some of the gelatine squeezes out, and the prints stick, and have to be taken off in bits with a knife and hot water. I have used —'s and also —'s papers with like results. Is it the fault of the paper or the manipulation?—**NEWCASTLE.**

The trouble is obviously in the manipulation, and this is proved by the gelatine squeezing out. Obviously this has been softened so much by prolonged washing or other treatment as to have become practically disintegrated. After washing for an

hour with six changes of water the prints should be immersed in a 5 per cent. solution of formaline for about five minutes, transferred to the methylated spirit bath for five minutes then squeegeed without drailing.

**ILLNESS OF MR. ALFRED WATKINS.**—We regret to learn that Alfred Watkins, of Hereford, president of the P.C.U.K., has met a serious motor accident. Whilst proceeding up a steep hill, the car containing Mr. Watkins and a friend, from some unexplained cause began to run backward. Mr. Watkins endeavoured to turn it to the roadway, but the car overturned, and whilst his friend managed to leap off in time Mr. Watkins was pitched heavily on to a pile of stones and rendered unconscious. He was taken to a farm for the night, and, though badly bruised and shaken, and the muscles of his leg injured, was able to be taken home next day. He is making good progress towards recovery, and it is hoped that in a few weeks he will be about again.

**THE ALHAMBRA.**—This leading home of entertainment, the cinematograph performances at which have consistently demonstrated the feats possible to animated photography, has now been decorated from floor to ceiling, a process which has been carried out without interfering with a single performance. The effect presented by the house is brilliant in the extreme, a blaze of light that is at the same time harmonious. And from the point of view of comfort (which, after all, is far more important than appearance), all the changes are for the better. The stalls have been re-seated, and are not only pleasant to sit in, but give plenty of room for one's feet and for persons passing backwards or forwards. The same has been done in the balcony and upper circle, while the general appearance provides its patrons with armed and cushioned seats. Entrances and exits have been constructed to and from the balcony and grand circle; the entire floor of the house has been either repainted or covered with new linoleum; the balcony lounge has been made a place of beauty, with mirrors, mural decorations, and charming designs in electric lights; and direct access to the stage is now possible not only from the Charing Cross Road entrance, but from Leicester Square. The Alhambra has always been worth visiting for the sake of the entertainment. One may now say that it is worth visiting for the sake of its own beauty.

**THE "PUSHAXE" COMPETITION.**—Messrs. Fuerst Brothers announce a competition to introduce to public notice the new "Pushaxe" developer which they are shortly placing on the market. The competition should prove extremely popular, as it is open to amateurs and professionals, the dealer also coming in for his share of the spoils. Ten prizes, varying from £30 to £1, are offered for negatives, lantern slides, and prints, all of which must be developed with the "Pushaxe" developer, each package of which will contain a necessary entry form, together with full particulars. The competition will be judged by Messrs. William Crooke and H. Walter B. whose decision will be final. Competition specimens, accompanied by entry form properly filled up, must reach Messrs. Fuerst Brothers, 17, Philpot Lane, London, E.C., before November 30, each being marked "Competition." The entry form must contain the name of the dealer from whom the developer was purchased. Three prizes of £20, £10, and £5 respectively will be awarded to the three dealers who obtain the largest number of customers.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received, and the approval of the Publishers, and advertisements are not accepted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

present exhibition at the "B. J." house of photographs by the N.P.R.A. closes to-morrow (Saturday).

final arrangements for the Photographic Convention to be Hereford from July 15 to 20 have now appeared. Some from the Convention book are given on page 412.

ers this week witnessed two trade exhibitions—that of lak Company at the Portman Rooms (closing to-morrow at), and Messrs. Gamage's, which remains open till June 8.

months' hard labour for a fraudulent canvasser was a sentence at Croydon last week. (P. 411.)

prosecution of the two M'Hughs at Liverpool for alleged from assistants in photographic businesses is being continued.

ful investigation of dark-room light-filters by Dr. C. E. K. and J. K. Baker was communicated to the R.P.S. on Tuesday (P. 417.)

ers in Bromide Prints.—We give some notes on the various connected with the epidemics of blisters on sulphide-toned es. The water supply is certainly a factor in the case, and bath which also hardens the prints is recommended. (P. 403.)

matic enlarging apparatus and an instrument for viewing nn photographs are among the patents of the week. (P. 413.)

ther discussion of orthochromatic matters took place at the P. last week. (P. 411.)

iter in a contemporary has published some interesting figures mercury intensifier. (P. 402.)

unexplained facts in connection with loss of density in the bath are the subject of some notes on page 402.

E. J. Wall, in reviewing the modern work in colour sensitising, es the connection of fluorescence with the sensitising pro- of a dye. (P. 406.)

## EX CATHEDRA.

### The Reflex Camera Exhibition.

The arrangements for the exhibition of reflex cameras and their products, in the shape of photographs, have progressed so far that there is no doubt of the great interest which the combined collection of pictures and apparatus will present. Among the reflex workers who are sending prints for exhibition are:—

G. W. Beldam.  
Herbert Bairstow.  
F. Martin Duncan.  
Gordon Chase.  
Dr. John W. Ellis.  
S. G. Kimber.

Charles Kirk.  
Percy Lewis.  
Arthur Marshall.  
Oliver G. Pike.  
W. Thomas.  
W. L. F. Wastell.

and, therefore, the exhibition will obtain a doubled interest from the information conveyed as to the methods of leading exhibitors. In addition to the firms already announced the following firms expect to send reflex cameras associated with their names:—

Spiers and Pond, Ltd.  
F. C. Clarkson.

We would again draw attention to the period during which the exhibition remains open, viz., June 13 to July 6.

\* \* \*

### The Canvassing Nuisance.

The heavy sentences which continue to be passed on fraudulent portrait canvassers do not appear to do much towards mitigating the evil, but they have the salutary result of showing the public in the most unmistakable manner the true nature of the business. That the best means of checking the evil is to give it all possible prominence has long been our policy, and to that end we have at times almost overburdened our columns with the police-court reports of the clever trickery which has duped so many poor people. Yet we are glad to find that such reports are of value to our professional friends who, as in the instance of Mr. Gordon Chase at Tunbridge Wells, have reprinted and distributed these exposures of the canvassers. Mr. Chase sends us such a circular which he has just issued, and we wish him well in using it to repulse this dishonest competition.

\* \* \*

### Dark-Room Anæmia.

The Departmental Committee appointed last August to inquire into the question of compensation for industrial diseases has just issued its report. We learn from it of one suggestion which was rejected, namely, that employment for long periods in photographers' dark-rooms might be the cause of chronic anæmia. As to what ground there is for the suggestion we do not know. We know many who are practically confined to dark-rooms for eight or ten hours a day, and we cannot recall one case of what might be called chronic anæmia. Many years ago Messrs. Lumière, of Lyons,

instituted the use of green light filters in their factory, and stated that they found that there was less irritability and peevishness amongst their employees. Possibly they employ a great number of female hands. It would be interesting to have the evidence of dark-room workers on this point.

### The Action of Light on Living Organisms.

That light can act therapeutically is, of course, well known, as, for instance, in the case of the Finsen light treatment. It has also been accepted for many years that the absence of light, or rather of the violet rays, was favourable in such cases as smallpox, measles, etc. In these diseases red light is used to illuminate the sick rooms. It is not necessary to enter into the subject of radiography, as the beneficial effects of the X-rays in certain cases are well known. That light does exert some action on living organisms is abundantly proved, and the analogy between the vegetable and animal kingdom may be in favour of the theory or idea that red light may cause anæmia; but it has also been recorded that plants thrive well when illuminated by red light only. Assuming the correctness of the idea that sunburn is due to the photographically active shorter waves of light, one might be tempted to argue also that absence of these waves would cause anæmia, but so far we do not think the case proved, at any rate, not sufficiently so as to warrant the inclusion in the third schedule of the Workmen's Compensation Bill, 1906, of workers in photographic factories.

### Loss of Density in the Fixing Bath.

The question has been raised in a contemporary. Why do negatives sometimes lose density in the fixing bath? It is, of course, fairly well known that in the presence of air and sunlight the fixing bath very vigorously attacks the silver image, but the query applies to the ordinary conditions of fixation. In the particular case in question the querist found that in cold weather his negatives lost density, and that an increase of pyro tended to obviate the loss. This points to under-development, and we believe it is a certain fact that imperfectly developed negatives do lose density, though a fully developed image will stand very prolonged fixation without any damage. It is generally assumed that the resulting thin image is simply the natural result of under-development, and that it is quite unnecessary to assume any solvent action on the part of the fixing bath; but while it may be easy to mistake an initial lack of deposit for an ultimate loss of deposit we do not think that this mistake has occurred, for we have noted many instances in which slightly under-developed negatives have come from the fixing bath in a very much thinner condition than it was at all reasonable to expect. As a matter of fact, if we assume the truth of the subsalt theory, a very feasible explanation is available, for, if subsalts are formed in the latent image in the conditions generally postulated, we may most reasonably assume that they are formed in the process of development, and, if development is incomplete, the subsalts must exist in the image when the plate is put into the fixing bath. In this case it is also reasonable to assume that the hypo will decompose the subsalt into silver and silver bromide, dissolving the latter. The net result, then, is that we have one atom of silver where complete development would have left two.

### The Developed Image.

The developed but unfixed image has, perhaps, not received as much attention as it deserves. If subsalts exist both in the latent image and in the developed image the latter is

likely to contain them in far greater quantity, in it offers a more promising opening for investigation. The fact that it is not simple silver, as is probably assumed, is proved by the readiness with which it is attacked by reagents that will not affect the metal. For example, a solution of potassium bromide will not affect silver at any rate, any appreciable extent. Yet it will reduce silver bromide, and so cause the ultimate loss in the fixing of part of the developed image. This action is somewhat useful, for surface fog is considerably reduced by a solution of potassium bromide. Fine details in the shadows are, however, also destroyed. A second fact suggests the presence of subsalts is the action of various substances added to the fixing bath. It has been stated that if either sodium chloride or sodium iodide is added to the hypo solution, density is lost, and a reducing action takes place. We have not tried either of these additions, but we have had experience of the reducing action of an iron fixing bath made by adding sodium sulphite and hydrochloric acid to the hypo solution, which additions do not result in the formation of sodium chloride. These effects can be accounted for by assuming the presence of subsalts for such a compound in the presence of a soluble hypo and sodium thiosulphate would no doubt be wholly converted to a soluble silver salt, and would, therefore, disappear from the image. It does not appear that over attention has been given to these reactions on the developed image, and it is not impossible that some good might be done from following up the subject.

### Silver Nitrate as a Remedy for Burns.

A German correspondent kindly drew our attention to what he alleges to be an error in our paragraph of April 15, 1910, attributing the recommendation of a 50 per cent. solution of silver nitrate as a means of allaying burns to Herr Coblenz. It may be remembered that we expressed surprise at this drastic recommendation and we are therefore glad to be informed that the author of the solution which is advised is a cold one containing ten per cent. of the silver nitrate. This has proved a valuable palliative application in the case of severe burns, although silver nitrate is not now the common inhabitant of photographers' shelves that it once was the prescription may, nevertheless, be worthy of note by those whose occupation exposes them to danger from fire.

### Intensification with Mercury.

Some useful quantitative results have been obtained by the use of mercuric chloride have been obtained by Mr. H. Lloyd-Hind, and published in the "Photographic Monthly." He finds that the amount of mercuric chloride required by each square plate varies from .014 to .277 grammes, according to the original intensity of the image, and that 100 c.c. of a 1 per cent. solution should be sufficient for fifty plates or one pint for 291 quarter-plates. Dilute solutions do give as much intensification as strong ones, hence it is advisable to throw away used solution when it begins to work slowly. A curious feature is the disappearance of the hydrochloric acid used to acidify the mercury solution. It appears that when 100 c.c. was used to intensify 100 quarter-plates 12 per cent. of the acid was lost. The author concludes from this that it is advisable to add acid from time to time to make up the loss, but we doubt the necessity for this. The acid is commonly used to facilitate the dissolution of the mercury chloride, and it appears to us somewhat doubtful if it plays any important part in the bleaching process. It is apparently used up, but this may be due to combination with the gelatine. The acid may facilitate

after washing out of the mercury solution, but it is safer to rely on a separate acid bath for this purpose. It would seem that a little more information with regard to the action of the acid would be desirable. We believe the general idea is that it assists in dissolving the chloride, and thus to preserve the solution, and facilitates washing; we do not think it is usually credited with any action on the image.

\* \* \*

#### Postcard Enterprise.

Like the journalist, the postcard publisher has to live up to Lord Curzon's demand as to the intelligent anticipation of events before they occur, and, like the journalist, it is rarely that he is in so doing. But when the leading firm of publishers of photographic postcards, on the very next day after the announcement of the Queen of Spain, places on the market a card purporting to represent the King, Queen, and their only-born son, one gets an unpleasant impression that the publisher's line of good taste which sets a limit to commercial enterprise has been overstepped. The publishers themselves must surely realise that no one in his or her senses credits the production with being a genuine photograph of the infant, but must surely regard it as an affront to his own intelligence. Photographers, still more, have reason to regret an act which, by inference and implication, casts the stigmas of sham and fake over photography in general. Our good friends have been too clever by

#### Convention.

From the full book programme of the Convention now published, we are glad to see that the arrangements for the meetings and excursions, to take place from July 15 to 20, have been satisfactorily made. We have already given the details of the latter part of the proceedings, so that it is only necessary to remind intending conventioners of the opportunities which await them in the ancient city of Hereford. Mr. Watkins, whom all will wish a speedy recovery from a recent accident, contributes to the Convention programme an interesting sketch of what is to be seen and photographed in Hereford, and the Dean of Hereford supplies a written guide to the cathedral, which is architecturally informative. The list of papers and demonstrations, the commendably short itineraries for the excursions, justify the belief that Hereford will not be one whit less popular as a Convention centre than the previous meeting places.

#### Do not to Artifice.

The human weakness for portraits is traded upon, as we all know, by every advertiser, but it is not often that the appeal to the public is made in such an utterly wretched and uncouth manner as it is on a circular issued by a firm of cigarette makers which has fallen into our hands. The designs from a hundred packets of these luxuries, we are entitled the purchaser to a portrait miniature in natural colours and framed in gold. A three-colour reproduction of his work of art appears on the circular, and though the colours are beautiful but one inch across there is one impression of the subject 1-16 of an inch out of register, with the result that the border of bright magenta surrounds the subject's outline, and gives point, as no other effect could do, to the words below:—"This printed reproduction gives but a poor idea of the artistic beauty of the originals." In the name of humanity we hope it does, and we hope, too, that the proprietors of ——— cigarettes know a little more about printed miniatures than they do about trichromatic print-

### BLISTERS IN BROMIDE PRINTS.

SINCE the introduction of toning bromide prints with sodium sulphide, blisters have become so common that it is a serious matter, as whole batches of prints may be spoiled at any moment. The blisters occur in such an erratic way that the ordinary photographer is unable to trace their cause to its source—or sources, for there are probably many. Some brands of paper seem more liable to this defect than others, yet different batches of the same maker's paper vary, and some will blister and some will not. It has been suggested that grease on the paper before coating with the sensitive emulsion is a probable cause. But this would produce large blisters, and the trouble is usually that the prints are covered with small blisters from one-eighth to a quarter of an inch in diameter, and the large ones are exceptional.

Before the days of sulphide toning blisters occurred, but the defect was not a common one. Several remedies were suggested, such as immersion in a solution of common salt, without washing, from the fixing bath; or a bath of methylated spirit in place of salt and water; but even then the cures often failed, and blisters frequently appeared. Prints on thin paper seemed more liable to blisters than prints of the same make on thick paper, yet postcard prints often show blister badly, though they generally disappear on drying. The local water supply no doubt has some effect in causing blisters; where the water is "hard," in a limestone or chalk district, blisters are less liable to appear, while in some of our large towns, such as Glasgow, Liverpool, Manchester, and Birmingham the water is "soft," being drawn from lakes (natural or artificial) in mountainous districts, being practically rain water, in which there are but small quantities of lime and other minerals.

The excellence of Burton beer is said to be due to a peculiar hardness of the water yielded by the wells in the district, and in other parts of the country brewers "Burtonise" their water by the addition of carbonate of lime and other salts. Unfortunately, photographers cannot do that, as the supply comes, as a rule, direct from the water mains; if large tanks were used it might be possible to harden the water before use.

A curious thing happened in Birmingham some two or three years ago, when local photographers were troubled by blisters suddenly appearing in untuned bromide prints. They were at a loss to account for it, until a letter appeared in the Press, from an amateur photographer, suggesting that it was caused by the arrival of the water from the new Welsh reservoirs. In a few months the trouble ceased for a few weeks, and then broke out again as badly as ever. It afterwards leaked out that the demand for water had been so great that the old supply of water from the wells, in the red sandstone, had to be requisitioned, and then the blisters ceased; then when the demand fell to its normal quantity undiluted Welsh water was supplied, and the blisters appeared again.

Medical men who practise photography find that bromide prints, developed in their chambers in Birmingham, blister, while those developed outside the town, where the supply comes from wells in red sandstone, do not blister.

The question then arises, how can photographers who are compelled to use a "soft" water prevent their prints from blistering? The answer is, by using a fixing bath containing alum. Many object to such a bath, arguing that it endangers the permanence of the print. If it is prepared in the haphazard way in which many men work it may, and probably will, affect the stability of the print. If the fixing bath is prepared by throwing a handful of alum into a solution of hyposulphite the prints fixed in it will turn yellow sooner or later. But if the bath is properly

prepared there seems no reason to fear any deterioration. Many manufacturers recommend an acid fixing bath containing alum, and for some of the newer brands of bromide paper, in which the paper support is thin, alum is an absolute necessity; and for many of the "Gaslight" papers on the market, an acid fixing must be used, if yellow prints are to be avoided.

A good formula, one well tested by long use, is:—

Water ... ..	64 ozs.
Hyposulphite ... ..	16 ozs.
Sodium sulphite ... ..	1 oz.

When the crystals are dissolved add  $1\frac{1}{2}$  oz. of glacial acetic acid, and finally 1 oz. of potash alum dissolved in 5 ozs. of water. A large stoneware jug can be used for mixing, and hot water hastens the solution of the chemicals; it should, of course, be allowed to cool before use. If properly mixed the solution should be only very slightly cloudy. The surface of prints fixed in this bath should feel "leathery" to the touch in about thirty seconds after immersion, and the bath should not be used too long without renewal. If the surface of the print is soft after a minute's fixing a fresh bath should be substituted at once. It is best to make up a gallon or more at a time, so that a stock of unused, fresh solution is always ready. If found more convenient it may be mixed double the strength, and diluted for use as required. After washing prints may be spread out to dry, face downwards, so avoiding curling. If the prints are to be toned with sulphide they must be dried before being toned, or they may blister; and any rough handling or buckling of the wet prints must be guarded against, as this is a frequent cause of blisters.

After the prints have been bleached by the photographer's favourite formula, they must be darkened by application of the sulphide, which must not be too strong—half an ounce of saturated solution of sulphide should be diluted with forty ounces of water—and the print should not remain in it any longer than is necessary to convert the iodide or other silver compound into sulphide. Only a few prints should be darkened at a time—each can be placed face down and pushed under the solution. When about a dozen prints are immersed they may be turned face up one by one, and in two or three minutes after the image is darkened as far as it will go, they may be removed one by one, and placed in a fairly strong solution of alum, without previous washing. They may remain in the alum solution until all are toned, the dish containing the prints is put under a stream of water, and prints turned over and over, so that the alum solution is gradually washed away; a very short washing in water is then sufficient.

The method recommended above is the result of years' practical experience in an establishment where bromide prints form 99 per cent. of the output. There are probably many causes of blisters, but if the above method be adopted not one print in a thousand will blister, if ordinary care is used in carrying out the process. Special stress must be laid on three points—first, an acid fixing bath containing alum; second, drying prints before toning; and third, removal to an alum bath from the sulphide solution without washing. Sometimes a white deposit will appear on the surface of prints when dry, but a slight rubbing with a tuft of cotton wool moistened with methylated spirit will remove it.

## ACCURACY AND EFFICIENCY OF MODERN SHUTTERS.

### I.

IN modern photography, especially when working with a hand-camera, short exposures are sometimes desirable; and thanks to the rapidity of modern plates, and the large working apertures of modern lenses, there is no reason why an exposure of 1-30, 1-50, or even 1-100 sec. should not be a full and correct exposure.

Now, owing to the enterprise of men like Watkins, Wynne, and Welcome, the modern photographer has great facilities for calculating correct exposures, and from my personal experience I should say that he is particularly anxious to give correct exposures when working at the higher speeds; but, unfortunately, the inaccuracy of most shutters, combined too often with a complete ignorance of the principles which determine the efficient exposures of these shutters, makes it impossible for him to give anything like the desired exposure.

When I speak of the anxiety of photographers to give correct exposures at the higher speeds, my experience is that a man who would debate as to whether he should give 1 or 2 seconds when uncapping his lens, will worry as to whether he should give 1-30 or 1-20 second when he works in fractions of a second; and the chances are that if he decides on 1-20 of a second, the shutter will give a total exposure of 1-30 sec., and the nature of the shutter will be such that the efficient actinic value of the light that reaches the plate will make this exposure equal to 1-90 of a second: less than  $\frac{1}{4}$  of the desired exposure. In fact, marking most of the between-lens shutters with small fractions of a second is like fitting a brown Bess with a telescopic sight.

#### Duration and Efficiency of Exposures.

With shutters of the roller-blind and between-the-lens types the duration\* of the exposure is the time which elapses from

the moment the shutter commences to open until the moment it finishes closing. The duration of the exposure is important when photographing moving objects, because the objects being photographed during the whole exposure, and, as everyone knows, an exposure of too long a duration blurs moving objects; but inaccuracy in the duration of the exposures marred on the shutter can easily be remedied, as Messrs. Beck, of Chesham, will test the shutter speeds and mark the correct speeds on a card for the small sum of fourpence.

But the actinic efficiency of the shutter is another matter—a very important matter for those who desire correctly exposed negatives. Supposing a sheet of cardboard (ABCD, Fig. 1) is placed before the lens, and an exposure made by slowly raising the cardboard to EF and, without a pause, slowly lowering it to its original position. If the actual duration of the exposure had been one second, the efficient exposure would have been only half a second, because the lens would have been partially covered during almost the whole exposure, and the average portion of the lens uncovered would have been one-half: 1 lens uncovered during one second = whole lens uncovered during half second. Efficient exposure, half second. This is what may happen with shutters of the roller blind type, in which the aperture is short in relation to the aperture over which it passes: a square opening in the blind passes before the lens, an average of half the rays of light is cut off during the uncovering of the lens, and a similar volume of light is

\* We are considering what may be termed the *local* duration of the exposure, i.e. the duration of exposure given to any one portion of the plate, in the present article.

the covering of the lens, and as the opening is but smaller than the lens, the whole lens is uncovered only during a portion of the exposure.

An iris or diaphragm shutter the efficiency is affected in a different and less certain manner. Imagine that a lens is closed with an iris diaphragm which closed altogether, and as exposure were given by slowly opening the diaphragm during the first half-second, and slowly closing it during the next half-second, so that the diaphragm was opening and closing during the whole exposure. A glance at Fig. 2 will show that if the iris is half open, a lens working at  $f/8$  would be equivalent to  $f/16$  and the value of the light rays quartered: one second's exposure at a nominal  $f/8$  would equal a nominal exposure of  $\frac{1}{4}$  second at  $f/16$ , and the average of exposures at  $f/64$ ,  $f/32$ ,  $f/16$ ,  $f/8$ , and the average of exposures at  $f/16$ : one second at  $f/16 = \frac{1}{4}$  second at  $f/8$ . Some of the shutters, such as the Göerz Sector, can open very quickly, in an open during most of the exposure; but an ordinary roller-blind shutter costing from 20s. to 30s. is most uncertain. It takes about 1-5 of a second, the shutter will open and close quickly, but not fully open for say  $\frac{1}{4}$  sec., and the efficient exposure would be about  $\frac{1}{4}$  sec.; but at 1-30 sec. the shutter will be opening

be seen that the front of this aperture, F, travels three inches during the exposure. During the first inch AB, the lens is being uncovered and the efficiency halved; during the second inch, BC, the lens is working at the full efficiency, and during the third inch, CD, the efficiency is again halved, whilst the lens is being covered—that is to say, the shutter is giving half efficiency during 2-3 of exposure, and full efficiency during  $\frac{1}{2}$  of exposure ( $\frac{1}{2} \times 2-3 + 1 \times \frac{1}{2}$ ) = 2-3. That is to say, the efficient exposure of this shutter is 2-3 of the duration of the exposure, and a nominal 1-20 sec. would be an efficient exposure of 1-30 sec. In shutters fitted to some of the very compact and neatly mounted lenses, the blind aperture may measure only  $\frac{1}{2}$  times the diameter of the lens aperture, in which case the efficiency would be reduced to 3-5 of exposure duration.

Granted that a roller-blind shutter works at the specified speeds, the following table will enable the photographer to calculate the efficiency of the exposure. Measure diameter of lens aperture and width of blind opening

When blind aperture	=	diameter of lens,	efficiency	=	$\frac{1}{2}$
"	"	"	"	"	"
"	"	"	"	"	"
"	"	"	"	"	"
"	"	"	"	"	"
"	"	"	"	"	"
"	"	"	"	"	"
"	"	"	"	"	"

Thus with an 8-inch lens working at  $f/8$ , i.e., a lens measuring 1 inch diameter, if shutter opening measures 2 inches, the efficient exposure at a nominal 1-20 sec. =  $1-20 \times 2-3 = 1-30$  sec.

#### The "Cleverex" Shutter.

Another type of shutter which comes under the same category as the roller-blind is the type in which a metal disc pierced with an aperture on one side is revolved across the lens field, Fig. 4. In the old form of shutter, such as that which Messrs. Lancaster used to supply, the disc was revolved by means of a spring, and the various speeds secured by means of a variable tension. The principle of these shutters was excellent, and, provided the duration of the different exposures was ascertained, the efficient exposures could be accurately determined by the foregoing roller-blind table. Unfortunately, if these shutters were laid aside with the spring at high tension, and such accidents will happen, the driving power of the spring would weaken, and the speeds become inaccurate.

The latest development of the disc shutter is Messrs. Beck's "Cleverex," which is an excellent shutter in many ways. In the "Cleverex" the disc is revolved by a simple spring, and the variations of exposure are obtained by altering the width of the disc aperture, and not by altering the tension of the spring; hence there is little probability of the shutter getting out of order. At the slowest "instantaneous" speed, 1-10 sec., the disc aperture is about four times the diameter of the lens, and the efficiency is consequently great: duration of exposure 1-10, equals an efficient exposure of 1-12 $\frac{1}{2}$  sec. But, unfortunately, as the speed increases, and the aperture is reduced in width, the efficiency decreases: 1-20 = efficient 1-30, which is not bad; 1-40 = efficient 1-80, which is not satisfactory; and 1-80 would not give an efficient exposure for any subject except seascapes. For pictorial hand-camera workers, this shutter might well be marked with durations of 1-10, 1-15, 1-20, 1-30 sec., giving an approximate efficiency of 1-12, 1-20, 1-30, and 1-50 sec. A high average of efficiency combined with accuracy.

#### Diaphragm Shutters.

The sector, iris, and diaphragm shutters are very pretty instruments, but their accuracy is very uncertain, and their efficiency often disappointing. A high-class shutter of this type, such as the Göerz "Sector," may work with accuracy and efficiency; but the cheaper and more popular kinds are as a rule inaccurate in the speed marking, and give very inefficient exposures at any speed greater than 1-20 sec.

ing during almost the whole exposure, and the effective exposure at 1-30 sec. would probably be only 1-100 sec. That is, an exposure of 1-30 sec., from start to finish, has been given, but the lens has only received the quantity of active light that would have been passed by an ideal shutter (one that opened and closed in 1-1,000 sec.) working at 1-100 sec.

#### Roller Blind and Similar Shutters.

As we have seen, the roller-blind shutter halves the efficiency of exposure whilst it is uncovering and covering the lens; the opening in most of these shutters is considerably wider than the lens, and consequently during a portion of the exposure the lens is entirely uncovered, and its action more efficient. If, therefore, a roller-blind shutter be fitted to a lens of 1-inch diameter, the lens-hood or lens-flange will probably measure quite 2 inches, and the opening of the blind will probably measure 2 inches. Now let us assume, for the sake of simplicity, that the two rollers are very far apart, so that the blind-aperture is a straight line during the exposure, and let us also assume that the blind is quite close to the lens; we can calculate the efficiency of the exposure from Fig. 3. Let L be a lens of diameter 1 inch, and S the blind aperture of 2 inches; it will

be seen that the front of this aperture, F, travels three inches during the exposure. During the first inch AB, the lens is being uncovered and the efficiency halved; during the second inch, BC, the lens is working at the full efficiency, and during the third inch, CD, the efficiency is again halved, whilst the lens is being covered—that is to say, the shutter is giving half efficiency during 2-3 of exposure, and full efficiency during  $\frac{1}{2}$  of exposure ( $\frac{1}{2} \times 2-3 + 1 \times \frac{1}{2}$ ) = 2-3. That is to say, the efficient exposure of this shutter is 2-3 of the duration of the exposure, and a nominal 1-20 sec. would be an efficient exposure of 1-30 sec. In shutters fitted to some of the very compact and neatly mounted lenses, the blind aperture may measure only  $\frac{1}{2}$  times the diameter of the lens aperture, in which case the efficiency would be reduced to 3-5 of exposure duration.

The last shutter of this class which I tested (it had been advertised and sold in the respectable company of a first-class anastigmat and an excellent camera) was marked at speeds from 1 to 1-100 sec. At 1 sec. it gave an exposure of  $\frac{2}{3}$  sec.; the nominal  $\frac{1}{2}$  and 1-5 sec. were both  $\frac{1}{4}$  sec.; and the 1-25, 1-50, and 1-100 sec. all gave an exposure of 1-35 sec. duration. But the worst fault of this one quick exposure was its horrible inefficiency, for more than  $\frac{2}{3}$  of the duration of 1-35 sec. was taken up by the opening and closing of the shutter, and the efficiency only worked out equal to a full exposure of 1-85 sec. So when one imagined that one was giving 1-25 sec., one was giving the plate an exposure only equal to 1-85 sec.

Now, as we have seen, the efficiency of a diaphragm shutter depends on two factors: the total duration of the exposure, and the duration of the time the shutter remained fully open. During the time the shutter is fully open the exposure is obviously efficient, but during the time the shutter is opening and shutting the efficiency is reduced to a quarter. Thus, say the total duration of an exposure be 1-25 sec., and half this time is spent in the opening and closing, we have 1-50 sec. full efficiency + 1-50 sec.  $\times \frac{1}{4}$  efficiency =  $1-50 + (1-50 \times \frac{1}{4}) = 1-40$  sec. actual efficiency.

I have never heard of the efficiency of these shutters being

tested, but it is quite a simple matter. The first factor—the duration of the exposure from start to finish—is tested in the usual manner, and the different speeds noted down. Second factor, the time the shutter is fully open, is next in the following manner. The centre of the lens is covered with a circle of black paper, so that only the extreme edge of the aperture is left uncovered, just enough to throw a faint light on the focussing screen; the various speeds are again tested, and the results again noted. It is, of course, obvious that the second test gives the time that the shutter is practically open (Fig. 5, A).

With the "Unicum" and "Automat" shutters, which are shown in Fig. 5, it will be found that the exposure is given by opening two thin metal plates with curved edges. With these shutters the time of remaining fully open is found by covering the lens except the portion which will come into action just as the shutter is open, C, Fig. 5. It will also be noticed that the curved plates give slightly greater efficiency than that given by the iris shutters, and the time of opening and shutting will be divided by three instead of by four.

In the next article I hope to give rules for ascertaining the efficiency of shutters, and discuss the focal-plane shutter.

A. J. ANDERS

## A REVIEW OF RECENT WORK IN COLOUR SENSITISING.

### III.

THE discovery of optical sensitisers was made by the late H. W. Vogel, and to him also is due the statement that a dye sensitised for the colours it absorbed<sup>1</sup>. To him also must be ascribed the discovery that the maximum of sensitiveness did not exactly coincide with the maximum of absorption, but was shifted towards the red. The most complete examination has, however, been made by Eder<sup>2</sup>, who measured not only the absorptions of dyed gelatine, but in the case of eosine the dyed silver bromide. Naturally, measurements of the latter are extremely difficult, not only on account of the high refractive index of the silver halides, but also because of the rapid darkening of the halides.

Eder's results and his papers, which are far too long to give in detail, led him to the following conclusions:—

1. That neither the absorption spectrum of the alcoholic nor aqueous solution of a dye, nor the dry-dyed gelatine, coincides with the position of the photographic sensitive maximum on gelatino-bromide of silver.

2. The sensitising maximum of the dyed silver bromide lies further towards the red than the absorption maximum of any of the solutions.

3. That specific gravity of silver bromide = 6.353 is so much greater than that of gelatine = 1.326, that one may well assume the greater specific gravity of the refractive medium as the cause of this shift. Although Kundt's law has many exceptions, there is very great regularity in these special cases.

Kundt's law asserts that the absorption band of a colouring matter is displaced towards the red as the refractive power of the medium in which the substance is dissolved increases. In accordance with this law, one would expect that the shift with the different halides would increase as their refractive indices, which for the melted halides (Keiser) are, for chloride  $n_D 2.0611$ , for bromide 2.2533, and for iodide 2.2787. I have been unable

to find any conclusive proof of this. Eder states that the position of maximum sensitiveness for chloride and bromide is in the same position, but Keiser finds that that for the chloride is about  $\lambda$  557, and that for bromide about  $\lambda$  563. As silver is not sensitised, this could not be measured.

But to return to Eder's conclusions:—

4. The position of the absorption maximum of the dye in solution and the sensitive maximum of the dyed silver bromide differs in the spectroscopic as a rule fairly regularly by about 300  $\mu$ . That is to say, those rays of light which act most on dyed silver bromide possess as a rule a shorter wave length than those which are absorbed by the dyed gelatine, without the silver bromide.

5. The absorption spectrum of silver bromide stained with eosine and the maximum of sensitiveness of the dyed bromide completely agree.

6. Variations of the absorption spectrum of dyed gelatine and the photographic action of the dyed halides ought not to be accepted as exceptions to the "absorption law," for the action spectrum of one dyed medium is no certain proof of absorption of another medium stained with the same dye.

Confirmation of Eder's conclusions have been given by H. Lumière<sup>3</sup>, Bothamley<sup>4</sup>, and others. Dr. J. J. Acworth<sup>5</sup> has examined this subject, and many of his results do not agree with Eder's, but this is explained by the fact that Acworth in many cases rather deeply stained plates, and thus introduced the factor of screening.

Acworth's work was particularly good because in every case he actually photographed the absorptions of the dyed plates, a plate panchromatised with chlorophyll, tincture of jaborandi, shifting the plate repeatedly so as to eliminate the action of

darkening of the silver halides. Those interested in the subject can turn up the above-mentioned translation, but it may be worth while to state his final conclusion, and that is "the cement of the maximum of sensitiveness in regard to the amount of absorption has not its cause in the greater dispersal density of silver bromide films, but finds its full explanation in the above communicated theory of Professor E. Wiedemann."

His theory of Wiedemann's<sup>7</sup> is as follows:—"The appearance of luminescence is a sign that within a molecule very energetic vibratory movements are present. Such increased vibratory movements must evidently occur in all cases where an absorption of an incident light ray takes place, if the absorption depends upon the enlarging of the amplitude of the vibrations in the molecule at the cost of the incident ray, which in those vibrations within a molecule becomes existing energy, which may be converted either into radiatory or into heat vibrations. We can have both of these occurrences as a kind of damping. By the absence of the first factor plays a great rôle, by absorption without development the second. If a body is decomposable by incident light, a decomposition occurs if, in consequence of absorption, the amplitude of vibration in the molecule has reached a certain magnitude. If, however, the amplitude remains under a certain greatness, no decomposition can practically take place. The value of the amplitude depends, however, on the absorption-coefficient's greatness, and secondly, upon damping. If the absorption is nil, then the value of the amplitude is nil, and likewise chemical action. If, on the other hand, the damping is very great, then the conversion of motion in the molecule takes place very rapidly, and, in spite of the absorption, no decomposition shows itself. Now, this damping is apparently the greatest for the places of strongest absorption; therefore, if we sensitise a plate with some suitable substance for the incident rays which correspond to this maximum of sensitiveness may not appear there, but somewhere else more or less adjacent to it."—(Acworth, *loc. cit.*) We find this statement of Wiedemann's we have no other author who does not ascribe the shift towards the red to the density or refractive index of the halide.

Though has been quoted, I think, to prove that whether we accept Eder's or Wiedemann's explanation, there is a shift towards the red as compared with the solutions and the coincidence of the absorption of the dyed halide with its sensitiveness. Turning our attention, then, to the next point, the connection between the character of the absorption of the dyes and sensitiveness of the halides dyed therewith, this must be at once accepted without question, for we find close similarity between the absorption of such a dye as erythrosine and its sensitiveness and that of leucine or nigrosine and the sensitiveness attained therewith. This is also proved by Von Hübl's work<sup>8</sup> and by Monpillard's.<sup>9</sup> It is universally recognised that this holds good, and so much at a preliminary examination of a dye solution will tell one of the kind of sensitiveness to expect. It is well established by the researches of Valenta on the isocyanines<sup>10</sup>, and on the absorption and sensitising action of some yellow dyes for the ultra-violet<sup>11</sup>.

In connection with the whole subject of absorption and sensitiveness see also "A note on a panchromatic emulsion of silver rosinate," by Mees and Wratten, "Phot. Journ.," August, 1907, p. 300.

At brilliancy of the colour of the dye has no special influence on the next point, and this will be at once conceded when the use of such dyes as erythrosine, a very brilliant one, and that of rulein S, or nigrosine, or diazo black, all of which are very dyes, are considered.

Or one may take the whole of the phthaline group, and at once see that the brilliancy of their colouring does not influence the sensitising action.

With regard to the fugitive character of the dye, the importance of this was, I believe, first propounded by Abney—at least, I gather so from his footnotes to Eder's early work, "The Chemical Effect of the Spectrum," which appeared first in the "Photographic Journal" for 1881-2, and was reprinted as a separate work in 1883. Against this view we have Bothamley's<sup>12</sup> experiments, which prove that the instability of the dye to light has no action. Again, cyanine is the least stable of all dyes, isochinoline red the next fugitive, yet neither are such powerful sensitisers as erythrosine. And alizarine blue bisulphite, which shows only very slight change even after a month's exposure to daylight, and yet it is a fairly good sensitiser.

If this theory held water, then one must assume that the oxidised or bleached dye added to an emulsion would produce reduction of the silver salt. Eder<sup>13</sup> has, however, painted a plate with cyanine solution which had been exposed to light for a year and turned brown, and yet found no action.

Mees and Sheppard state<sup>14</sup> that "there is a probability that the sensitising power of a dye is connected with instability to light, but quantitative confirmation appears to be lacking. Dicyanine, for instance, is extremely unstable, but a weak sensitiser, while rose benzal is stable, but a good sensitiser." The example quoted is, therefore, directly opposed to their assumption. It must not be forgotten, too, that "instability" is a relative term only—that is to say, it refers to the dye under stated conditions. Under others the dye may be "stable." This is a well-known fact in ordinary dyeing, and indigo, for instance, may be extremely unstable on wool, and yet fast on cotton although used under the same conditions. Is it fair, then, to argue because a solution of the dye is unstable, that the dye shall be equally so on a dry plate?

With regard to the fluorescence of the dye having no action, one can at least say that the presence of fluorescence does not cause increase of colour-sensitiveness, and this is amply proved by the fact that of the phthaline dyes the strongest sensitiser, erythrosine, when pure, has absolutely no fluorescence at all; yet most of the other dyes of this class fluoresce and yet are not such good sensitisers. In fact, one is almost tempted to argue that fluorescence is not a supporter of colour-sensitiveness, but an actual deterrent to the latter.

The subject of fluorescence is an extremely complicated one, but it has been proved by Tyndall in one of his lectures that it is not a momentary phenomenon, but persists for an appreciable period of time. If, therefore, a fluorescent dye be added to an emulsion, one can well understand why there should be chemical action at the position of fluorescence, for the fluorescence or luminescence may persist long enough to cause an appreciable action—that is, appreciable on development, on the silver halide.

It is also capable of proof that some of the organic dye solutions fluoresce not only in ultra-violet but also in the visible spectrum. This is well seen with naphthaline red, which fluoresces throughout the whole of the spectrum except the extreme red; most of the phthaline derivatives, too, fluoresce in light which is of visible wave length, not necessarily the ultra-violet, to which region at one time fluorescence was supposed to be alone due.

For those who wish to follow this subject further, I would recommend Lewis Wright's "Light" (Macmillan), chapter VIII., and, for readers of German, Stark's papers in the "Physikalische Zeitschrift," 1905, p. 892; 1906, pp. 249, 355; and 1907, p. 81. To consider in detail Stark's statements would absorb far too much time and space, and they bear solely on fluorescence, and not in connection with dyes.

# THE DAYLIGHT SENSITOMETRY OF PHOTOGRAPHIC PLAT AND A SUGGESTED STANDARD DISPERSION-PIECE.

## III.

### [Daylight (Variation in Colour).

It has been many times stated that daylight was utterly unsuited for sensitometric tests, because of (1) the difference in the intensity of the various hues as the slit is illuminated by white cloud or blue sky, and (2) the variation in general brightness-intensity. Experiments were made to determine the actual difference in the first instance, by using the replica-grating spectrograph as just specified. The instrument was so arranged that the axial line of the collimator pointed directly to the zenith. Immediately over it was held a Zeiss apochromatic lens of 314 mm (12.4 in.) focal length, which formed an image of the cloud upon the slit-plate. Several exposures were made on different dates, and on various makes of plates, only such days being chosen as presented well-defined cumulus clouds in a clear and intensely blue sky. Care was taken that the slit was entirely filled with the cloud-light or blue sky, as the occasion demanded, and exposures were made to immediately follow one another, the exposure times being from 5 seconds to 1½ minutes, and on the same plate.

The results were exceedingly interesting, the negatives from the blue sky showing, as was to be expected, an absorption of the complementary hues at the least refrangible end. This absorption was, however, but slight in general. Those negatives whose timing showed the greatest contrast-difference were selected for measurement, together with a plate exposed to the spectrum from the same sky, but with the lens removed and a sheet of ground glass interposed in its place.

Density measurement of these negatives gives the results as detailed in Table III.

TABLE III

WAVE LENGTH.	DENSITY.		
	(Blue Sky.)	(White Cloud.)	(Ground Glass.)
3,640 .....	0.1750	0.2122	0.6731
3,780 .....	.4536	.3956	.8401
3,830 .....	.7106	.6498	1.1121
4,120 .....	1.2124	1.2638	1.2681
4,370 .....	1.0702	1.1436	1.2182
4,780 .....	0.4592	0.4992	0.5112
5,020 .....	.1172	.2234	.2194
5,220 .....	.1218	.2012	.1896
5,410 .....	.1836	.2739	.2400
5,570 .....	.0952	.2619	.2109
5,730 .....	.0494	.1261	.1253
5,940 .....	.0382	.0676	.0666

When plotted, these results give the curves of Fig. 7.

It will be noted that the difference between the secondary maxima in the yellow-green, when expressed in density, = 0.11, and this amount will be still further reduced if the "blue sky" negative had been exposed for a slightly greater length of time. The strong absorption in the ultra-violet from  $\lambda$  3400 to  $\lambda$  3700 in the "cloud" and "sky" negatives is, of course, due to reflection and absorption by the component parts of the lens-system. On the other hand, a change in altitude of the observer would show a still greater difference, the "blue" of the sky becoming more intense as the altitude increased, and necessitating an increase in the exposure time.

Comparison of these results, together with comparison of exposures made when the collimator formed an angle of 25 deg. with the plane of the horizon (which, of course, showed considerably less difference), indicates that daylight from a low angle, when properly diffused, is a sufficiently reliable guide for practical tests in selective sensitiveness. The second objection will be dealt with presently.

### Hurter and Driffield's Investigations.

To correctly understand and appreciate the argument advanced for the use of daylight as a standard in plate-testing necessitates a fairly clear understanding of the work of Hurter and Driffield, whose "Photo-chemical Investigations" first raised photography from

mere rule-of-thumb practice, and placed it upon a definite basis of scientific fact. They discovered and enunciated the laws governing the action of light and development, and furnished a terminology which is not likely to be supplanted. Unfortunately, for some known reason, the important results of these eminent workers but little known in America, and one may therefore be pardoned briefly recapitulating these points which bear directly upon the present paper.

The first great distinction made by them is in the definition of terms "opacity" and "density," which are in ordinary use synonymous. *Opacity* is defined as representing merely the optical property of the reduced silver in the negative to impede the passage of light; *transparency* is therefore the inverse of this. *Density*, on the other hand, is a physical measure of the amount of silver reduced in the film, and is expressed as the logarithm of the opacity, thus

$$D = \log \frac{I_1}{I} = \log \frac{1}{O},$$

where  $I$  = the intensity of the light transmitted,  $I_1$  = the intensity of the incident light, and  $O$  = the opacity. This distinction between opacity and density must be firmly fixed in the mind.

Fig. 7.

If a plate be impressed with a series of different accurate exposures increasing in geometrical progression, as 1, 2, 4, 8 . . . . 256, developed, and the resulting scale of opacities be measured, it will be found that if the logarithms of these opacities are plotted (ordinates), there will result a characteristic curve. The central portion of this is practically a straight line, and throughout this straight portion the deposits of reduced silver (blackening) will increase in arithmetical progression, as 1, 2, 3, 4, . . . . 9; that is, there is a definite logarithmic relationship between the amount of light action and the action itself. The density unit is the density of a deposit which transmits the tenth part of the incident light.

The enunciation of the law of "constant density ratios" provoked considerable controversy from photographic workers in general; while the investigators' conclusions were disputed, they advanced to the support of their statements definite scientific proofs which confirmed them. It was found that the relation existing between amount of light and the density-ratios is fixed and unalterable by constitution of the developer, or time of development; the opacity ratios are, however, altered. For example, suppose that a plate exposed to light for a definite length of time behind a revolving sector-disc with graduated apertures be cut into two portions, each portion be then developed for a different length of time,

<sup>16</sup> "Journ. Soc. of Chem. Industry," May 31, 1890.

and obtain as a result negatives which differed greatly in their appearance one from another; that is, that one which had received the shortest time of development would be what is termed a "thin" negative, while that receiving the longest time of development would be what is usually termed "contrasty." Yet the ratio existing between densities would be identical, although the opacity-ratio varied, the same in development causing the various densities to grow, but in such a manner that they would still bear the same ratio to one another. When the opacity-ratio is the same as the ratio of exposure, the negative is the true inverse of the original. The determination of a characteristic curve shows that a plate has considerable "latitude" in exposure,<sup>17</sup> so that negatives developed together which had received greatly different exposures would yield identical prints, provided that the exposures lie within the straight portion of the curve.

On the other hand, in the case of two negatives developed for precisely similar length of time, but with one exposure double that of the other, we have the opacity-ratios constant, while the densities

In other words the extra exposure simply means the addition of an equal amount of deposit on the varying densities composing the negative, and merely affects the time required in printing. To such extent is it possible to vary the exposure time (with constant development) that increasing exposures of from one to sixteen times will produce identical prints, the only real difference between them being the time occupied in printing. The negatives, however,

Fig. 8.

are vastly different from one another. This fact was exceedingly illustrated recently in a photographic magazine.<sup>18</sup>

#### Variation of Mean Intensity in Daylight.

With this explanation we may now consider the second objection to the use of daylight—namely, the variation in the mean intensity. It will readily be perceived that this intensity-variation, of course, amounts to nothing more than an alteration in the length of exposure, therefore comes under the jurisdiction of the law expressed in the preceding paragraph. In order not only to test the validity of the law but also to obtain a personal measurement of the photographic change during the course of a few hours, the following exposures were made with the revolving sector-disc,<sup>19</sup> under conditions as specified. The record detailed in Table IV. is from the laboratory notebook.

"Latitude" is defined as the ratio of the exposure at which over-exposure commences to that at which under-exposure commences.

F. Dundas Todd, "Development, Scientific and Practical," "Photo-Beacon," No. 1904.

The sector-disc exposure machine was constructed somewhat similar to the one of Mees and Sheppard ("Journal Royal Photographic Society," July 1, 1904, p. 229), but fitted with a removable cap pierced with a 4.0 mm circular aperture and covered with ground glass for use with daylight. When working with constant acetylene light, the cap is removed and the burner instantly placed in position.

All four plates were developed together in the same tray with Kodak D19, for two minutes, at a temperature of 17 deg. C., and when fixed and dried were carefully measured, and the densities plotted. The resulting curves are shown in Fig. 8, and it will be readily seen that they bear out very exactly the theoretical requirement that they lie parallel to one another. Their density-ratios vary, but their opacity-ratios are constant. Between 1 p.m. and 4 p.m.

TABLE IV.

Sky bright and sunny. Plate, Seed "27" Emul. 11,168; Oct. 12, 1906.

Plate No.	Time of Exposure.	Position on Plate.	Length of Exposure.	Remarks.
1	10 A.M.	Upper half	3 min.	Blue with white clouds
1	10.30 A.M.	Lower half	"	Blue with white clouds
2	11.15 A.M.	Upper half	"	Slightly brighter
2	12 M.	Lower half	"	Slightly brighter
3	1 P.M.	Upper half	"	Still brighter
3	2 P.M.	Lower half	"	Intensity about the same
4	3.15 P.M.	Upper half	"	Slightly duller
4	4 P.M.	Lower half	"	Light much weaker

Two exposures on each plate. All four plates cut from one large plate.

Fig. 9.

there is an indicated difference in light-action of  $2^{1.3} = 2.5$  times, which allows for considerable fluctuation in light-value. But that this is by no means a limiting value is shown by the parallelism of the curves in Fig. 9, which represent a difference in light-action of 23.3 or 9.8 times. There is no difficulty in obtaining any amount of corroborative data in this connection.

It should be remembered, that with varied exposure and equal time of development, we obtain, as the exposure is increased, an addition of an equal density (or fog) to the complete negative; but this increase of density does not in any way alter the opacity-ratios existing between the series of exposures on the same plate (throughout the straight portion of the curve), such opacity being governed by the development: there is no alteration in the gradation. Hence the curves of two differently exposed spectra would, as a whole, be parallel to each other, although the height of the ordinates (densities) would vary.

#### Irrationality of Plate Curves.

To be able to refer to the speed of any particular plate as possessing

a definite numerical value presents advantages which cannot be disputed. But if such a numerical value is based upon some source of selective radiation which differs from daylight, such as a candle, in the case of Hurter and Driffeld, the screened acetylene light of Mees and Sheppard, or the benzine lamp of Eder,<sup>20</sup> then the comparative speed-values obtained for "ordinary" and orthochromatic plates, are certain to be unreliable to a greater or less extent, dependent upon the closeness of the approximation of the artificial standard to daylight, and they must therefore be accepted provisionally.

A method commonly in use in testing the speed of one plate against another, is to expose the two plates to identical amounts of the same light-action, and then develop them together in the same tray for a similar length of time, and compare the resulting negatives. Pro-

Fig. 10.

vided that both plates have a similar composition, the method cannot be objected to; but when the plates in question are possessed of a different chemical constitution (the consideration of orthochromatic plates being laid aside for the moment), such a method is very liable to lead in many cases to most erroneous conclusions.

If two pairs of differently constituted plates ( $A$ ,  $A_1$ , and  $B$ ,  $B_1$ ) be exposed simultaneously to the same light-action, and then developed together, giving one pair double the length of time of the other, as  $AB=3$  minutes, and  $A_1 B_1=6$  minutes, it is very common to find, that with the first pair where  $A$  possesses a greater density than  $B$ , in the case of the second pair with the lengthened development, the effect would be entirely reversed, and  $B_1$  will have a greater density than  $A_1$ . The following series of plates was therefore prepared: a Seed "27" and a Cramer "instantaneous isochromatic" were exposed to precisely the same amount of light-action behind the revolving sector-disc, and then cut into eight strips each in the dark room. All of these strips began development together in the same bath at the same time, but, at stated intervals, each pair of plates ("27" and "Iso.") was removed from the developer together and passed directly into the fixing bath.

<sup>20</sup> Eder and Valenta, "Beiträge zur Photochemie" (French translation by Belin, entitled "Système de sensibilité")

From the measurement of these negatives the curves shown in Fig. were plotted, and serve well to illustrate this phase of plate-action.

It will be noted that, with but one exception (8 minutes), no pair of plates gives curves which are parallel to themselves. The gradation of the two plates is entirely different. In the present instance the Cramer plate is known to be slightly slower than the Seed, and hence it will be perfectly correct for the curve of the former to be lower than that of the latter; but it will be seen that, if we measure the distance apart of these curves representing the various development times, it is a constantly decreasing quantity up to a certain point, namely, that at which the slope of the straight portion of the curves are similar; and from that point on, the conditions are absolutely reversed, and the isochromatic plate acquires a greater density than the "27," and appears the faster plate of the two. Under the method of equal time of development, therefore, no true deduction could be made regarding the relative speed of these plates from any of the eight pairs of curves shown.

It has been shown by Abney<sup>21</sup> that a change in the gradation-curve takes place when the exposure is to light of differing wave-length, the curve becoming steeper; that is, the contrasts are more marked as the wave-length increases. In the present instance with normal development the curve of the "Iso" plate is less steep than accompanying "27" plate, although it is sensitive farther toward the less refrangible end of the spectrum. It would, appear, therefore, that the change in the slope of the curve is due mainly to constitutional (chemical) difference between the two plates, which leads to a difference in the velocity of the chemical reaction in ordinary development.

In order, then, to obtain a direct comparison between two plates, it is necessary not to develop for precisely similar lengths of time, but for precisely similar amounts of development-action—i.e., reduction product; under which circumstance the gradation-curves will be parallel to one another. In trichromatic work, where different plates are used and the development is for equal times, as is very common in the case, this change in the gradation-curve due to constitutional plate-difference must therefore be as carefully guarded against as the change in gradation due to difference in wave-length, if the true colour-value of the object be seriously considered.

#### Development Factor.

In the development of either the spectral records or the sector-disc exposures it will be evident, therefore, that the duration of development is of considerable importance. Hurter and Driffeld have named the amount of development received by a plate the "development factor" ( $\gamma$ ). This factor may be calculated from their formula

$$\gamma = \frac{D_2 - D_1}{\log E_2 - \log E_1},$$

where  $D$  and  $D_2$  are two densities selected from the straight portion of the curve, lying as far apart as possible, and  $E_1 E_2$  = the relative exposure times for the densities considered. It was shown by these workers that when  $\gamma=1.0$  the negative is the true inverse of the original; when greater than 1.0, the contrasts of the original are increased; while if less than 1.0 they are diminished. In testing diffused daylight it is not possible to obtain the values of  $E_1 E_2$  expressed in c.m.s. (candle-meter-seconds); nor for practical results is it essential. If one takes instead the ratio of the light-aperture in the revolving sector-plate, results of sufficient accuracy may be readily secured.

In the sector-disc made by the writer the apertures were cut in brass with much care, and the edges bevelled. Yet, notwithstanding all efforts to the contrary, the error on the smaller apertures was considerable. This error may be noted by comparison with the theoretical ratio, thus:—

Theoretical ratio = 1,	2,	4,	8,	16,	32,	64,	128,	256
True ratio = 1.04,	2.03,	4.06,	7.94	15.83,	31.84,	63.8	127.6,	256.0 <sup>2</sup>

When it is borne in mind that in the everyday practical sensitometry of photographic plates use is made of those obtainable commercially and not of an article specially coated on an accurate surface, it will readily be appreciated that the use of the theoretical aperture-ratio

<sup>(21)</sup> "On the Variation in Gradation of a Developed Photographic Image," Proc. R. S., 68, 300, 1901.

<sup>(22)</sup> My best thanks are due to Professor Raymond Burnham, of the Armour Institute, Chicago, for the measurement of the disc apertures.

within the limits of "plate error"; to make use (except for work) of the true ratio is an unnecessary refinement. value of  $\gamma$  may also be obtained graphically by drawing a line to the straight portion of the characteristic curve, starting from point 1.0 in the log E scale; for, as expressed by Hurter field,  $\gamma = \tan \theta$ , where  $\theta$  is the angle of inclination of the line from the horizontal base-line. The value is read directly from the density-ordinates. In practice, the writer finds it convenient to shift this 1.0 point two divisions to the left along the scale, and thus economise space.

constant  $t_{\gamma}$ , (the time necessary for any plate to reach a development factor of 1.0) advanced by Mees and Sheppard, which is a value in the indication of the development speed of various plates may be determined by the method of Drifford for determining the development factor.<sup>23</sup> The development factors ( $\gamma$ ), extracted as described, are now plotted with the time of development as abscissae, and the two development factors as ordinates, which, when plotted with the zero point, determine the curve. Take, in illustration, the "27" and Cramer "instantaneous isochromatic" plates

FIG. 11

which were exposed behind the sector-disc, and developed at a temperature of 17 deg. C. for from 1 to 12 minutes respectively. The replotted curves in Fig. 11 the development time necessary for  $\gamma_{1.1}$  may be read off directly as indicated—viz., 3m 10s and 3m 15s respectively.

ROBERT JAMES WALLACE.

(To be continued.)

# HEAVY SENTENCE FOR CANVASSING FRAUDS.

Arrested at the Croydon Borough Police Court, Edwin Morton, 25, New Road, South Norwood, was charged on remand with using £s. by false pretences from Charlotte Gammon, and 2s. from Annie Rudkin by false pretences.

Two young women are employed by Mr. S. G. Edridge, the Clerk of the Court, as cook and housemaid, and their story was that in their last the accused went to the back door and asked if they liked to have some photographs taken. They consented, and gave him the money, but did not see the man again until April 26, when he again called at the house and they accused him of having stolen their money.

At Morton's house, it was alleged, the police found some old receipt books and a large quantity of photographs. Taking the addresses from the receipt books, Detective Cadby made about forty inquiries at Beckenham, Anerley, Penge, Crystal Palace, and neighbourhood, and found that Morton had defrauded about fifty servants of money, and that on two occasions he was given a half-guinea and left to get change, but did not return. One girl, who received 15s. a month, gave him a half-sovereign, and he left a book with her as security, but did not return. The police had received between five and six hundred complaints.

Detective-Sergeant Easter said there were similar cases in Carshalton, Sutton, Norbury, and West Dulwich.

Morton, a prisoner, who pleaded guilty, was sentenced to three months' imprisonment with hard labour.

## A WAVE OF ORTHOCHROMATISM.

IN reference to the recent paper by Mr. E. A. Salt, which appeared in our issue of May 10, a paper was read by Mr. E. Human at the London and Provincial Photographic Association on May 24, Mr. A. E. Smith in the chair. The lecturer took exception to many of the points raised by Mr. Salt. Speaking of the difference noted by Mr. Salt between negatives taken on a screened ortho plate and those made on an ordinary plate, such difference being something apart from the rendering of colour values, Mr. Human contended that the difference could only be one of tone value, and instanced a subject such as a spring landscape in which the tones of green would be rendered in their proper differences on a screened ortho plate, but not upon an ordinary plate. The lecturer believed that an ortho plate used with an adjusted screen was capable of giving reproductions of light and shade in a subject at least twice as good as that of an ordinary plate, the gradation in which frequently inclined to "soot and whitewash." Mr. Human thought that if an ortho plate would do better, as Mr. Salt admitted it would, on some occasions it would do better on all, and he went so far as to say that even for copying black and white line work results could be obtained on an ortho plate which were superior to those on an ordinary. For flower subjects the rendering with ordinary plates might be fair with a prolonged exposure, but it was much better when an ortho plate was used. It was only by the use of an ortho plate that the texture of petals, etc., could be obtained at the same time as the delicate tones of the colour of the flowers. Mr. Human thought that flower-photography was unknown before the introduction of ortho plates.\* As regards portraiture, an instance was given of a red-haired girl, who had been unsuccessfully photographed by several professionals, but whose tonal values yielded to an orthochromatic plate properly screened. The importance of the proper adjustment of plate and filter was strongly emphasised, and in conclusion the lecturer challenged Mr. Salt to select his own subject and to obtain a photograph by using ordinary plates. He (the lecturer) would undertake to obtain a better result on orthochromatic plates, whatever the subject, and he also made an offer on behalf of a friend to obtain a better photograph of a flower subject on ortho plates and filters than with an ordinary plate.

In the discussion, Mr. W. T. Wilkinson said that he agreed with all that Mr. Human had said, but he found the one great drawback in ortho plates was their speed, the fast ortho plate had not any more ortho value than the slow. If the filters were not properly adjusted he found that the tone value of the greens was rendered far too black, and for the best results the filters, as had been stated, must be properly adjusted to the plate.

Mr. W. R. Stretton said that after using ortho plates for some time he had altogether discarded them for the ordinary brands. He thought that in pictorial work, at least, there were two factors that should be considered, when discussing the subject under notice—first, the personal one, and secondly, the development, because unless a plate was properly developed, no matter what plate was used, the result would prove a failure. He disagreed with Mr. Human's remarks upon the rendering of the greens, and could obtain good rendering by the aid of ordinary plates without any screen, and he thought that under certain circumstances there was a difference in rendering between ortho and ordinary plates which was not always to the advantage of the ortho. When working on the river the ortho plate with filter cut out the distance, but with an ordinary one he had succeeded in obtaining the distance and smoke from cottage chimneys against a blue sky. What needed to be taken into consideration was the personal element in development; this to his mind was the root of the matter.

Mr. Teape pointed out that the artist, when painting, produced his effect by a scheme.

Mr. Rapson said that Mr. Human had made one or two statements that seemed to him rather rash. One could not use the same class of plate for a soft as for a hard effect, and for copying black and white he thought the ordinary plate would do as well as the ortho. With regard to the filters, he had one which flattened the results,

\* The lecturer is evidently not cognisant of the fact that Mr. Henry Stevens, whose photographs of flowers have probably never been equalled, and who obtains a most realistic reproduction of texture, has done all his work on ordinary plates.—Eds. "E.J."

<sup>23</sup> "Photographic Journal," 43, 17 January, 1903.

for it had gone blind, and so killed contrast. Such a screen would naturally knock the life and sparkle out of a negative. Ortho plates were, he thought, always poor in the greens, being more sensitive to the yellow than the green. He always used ortho plates where needed.

Mr. Burgess did not understand where the value of ortho plates came in when copying black and white.

Mr. Haddon said that Dr. Mees had stated that the best rendering of such subjects was obtained by colour-sensitive plates and filters. Mr. Rapson had, he continued, admitted that the ortho plate was the best when taking a photograph of a garden, and what was best for the one was best for the other.

Queried as to the green trees only reflecting white light, Mr. Haddon said that if only white light was used the greens would appear as if dusted with flour.

Mr. Teape thought that this could be overcome by excessive exposure.

Mr. Freshwater had obtained flower studies on ordinary plates that were, he thought, not much behind those done on ortho, but when photographing geraniums he found he obtained a difference in the greens on ortho plates, the markings of the leaves being far better.

### LANTERN PROJECTION DISTANCES.

(From "Popular Astronomy.")

THE usual published tables of size of disc for a given distance from screen with a three-inch slide for different focus lenses in projection are perhaps near enough for all ordinary exhibition purposes, but not sufficiently so for accurate projection calculations. The tables give a constant ratio between disc and distance, the same as a pin-hole lens would give, whereas the conjugate focus of an objective naturally makes the disc greater in proportion than the distance calls for, amounting to nearly 18 inches on a 21-foot disc with a half size objective, as in the table herewith, from actual experiments by the writer on the 73-foot floor of the Portage armory, February 5, 1907, through the courtesy of Company F, third regiment, some of the members of which kindly assisted with the measurements. The alternating ten ampere arc lamp was used in the lantern. The objective was half size,  $9\frac{1}{2}$  inches equivalent solar focus, and according to the one-fourth equal image distance, the slide, a hymn, words and music, full field, having a three-inch exact mask, was focussed sharp at half way from centre to edge.

As a three-inch slide is a rarity, and  $2\frac{1}{2}$  inch horizontal being the almost universal width, a column is also given for discs from this width, which ranges tolerably close enough to the usual tables for ordinary purposes. The ratio of slide to focus should be the same as disc to distance, and is closely.

TABLE OF LANTERN PROJECTION DISTANCES.

H. W. GRIGGS.

FROM THE HEALTH RESORTS DEVELOPMENT ASSOCIATION, 29, John Street, Bedford Row, London, W.C., we have received copies of the official guides published by them for the Corporation of Deal, Leamington Spa, and Southwold. These booklets, which are copiously illustrated, contain interesting particulars of the several towns and surrounding districts, with advice as to how to get there, where to stay, what to see when there, and many other useful items of information. A copy of the desired guide may be obtained free on application to the Town Clerk at either of the above resorts.

### THE PHOTOGRAPHIC CONVENTION AT HEREFORD JULY.

THE Handbook of the forthcoming meeting of the Convention Hereford in July, under the Presidency of Mr. Alfred Watkins J.P., is to hand, and, judging from its contents, conventioners expect a right royal time during their visit to that ancient and toric city, than which, and the surrounding district, it would be difficult to find a spot more full of photographic promise. By courtesy of the Corporation of Hereford the use of the hands Town Hall, as the place of meeting, and a suite of rooms, have been placed at the disposal of the Convention for the week. The following is the programme of arrangements:—

#### MONDAY, JULY 15.

Morning.—Members of the Local Committee will attend at Town Hall to conduct parties to places of interest in and around city.

Afternoon at 2.30.—Reception at the Town Hall by his Worship the Mayor, Mr. G. J. Caldwell, J.P., who will be supported by members of the Town Council, the President, Mr. J. S. Arkwright M.P., the Committee of the Herefordshire Photographic Society and members of the Woolhope Club.

At 3 o'clock.—The President, Mr. Alfred Watkins, J.P., will deliver his inaugural address, after which a paper on "Microscopic Researches on the Gelatine Film" will be read by Dr. W. Scheffé.

Evening at 8.—Conversazione. Official reception by the Mayor of Hereford. Exhibition of pictures and apparatus, musical performance, refreshments, etc.; also an exhibition, specially arranged by Mr. W. T. Carless, the hon. local secretary, of ancient charters, plate, and insignia of the city of Hereford.

#### TUESDAY, JULY 16.

Morning, 9.30.—Excursion by brakes to Weobly and Pembridge, both of which possess an interesting old church and numerous ancient buildings.

Evening, 8.30.—Annual general meeting in the Town Hall, followed by a meeting of the new Council.

#### WEDNESDAY, JULY 17.

Morning.—Visits to the cathedral, where the Dean will arrange to meet the members at 11 o'clock, the markets, churches, hospices and other objects of interest in the neighbourhood.

Afternoon, 3.—The President and Mrs. Watkins "At Home" at the Vineyard Croft. Boating, punting on the Wye, canoe studies, woodland bits, etc. The official Convention group will be taken by Mr. Herbert Unwin in the adjacent grounds of the Vineyard (by kind permission of Miss Parry) at 3.30.

Evening, at 7.—The annual dinner at the Green Dragon Hotel.

#### THURSDAY, JULY 18.

Morning, at 9.20.—Excursion by train to Ludlow, Stokesay, and Ludlow is particularly rich in subjects of picturesque beauty and historical interest, amongst which we may mention the church, Castle, the Feathers Hotel (one of the most elaborately decorated timber houses in existence), and the Whitcliff walk, with Ludlow and the bridges. Stokesay Castle is unique in being an earthen fortified manor house of the thirteenth century in good preservation which has neither fallen into decay nor been "restored."

Evening, from 7 to 8.—A meeting of professional photographers in the committee room.

Evening, at 8.30.—A paper will be read by Mr. E. J. Humphreys entitled "A New Aid to Pictorial Photography," followed by a paper by Dr. C. E. Kenneth Mees and Mr. S. H. Wratten, entitled "Variations of the Watkins Factor, with Modification in the Conditions of Development."

#### FRIDAY, JULY 19.

Morning, 9.55.—Excursion by train to Goodrich and Symonds Yat. At Goodrich the chief objects of interest are the two extremes of the ruins of a Norman castle, and a modern mansion Goodrich Court. The road from Goodrich to Symonds Yat (two and a half miles) is rich in picturesque scenery, and the landscape photographer on the search for pictures will find them here without difficulty.

Evening, at 8.30.—A lecture entitled "The Romance of Insular Life," by Mr. F. Martin Duncan.

on the previous day, a meeting of professional photographers was held in the committee room from 7 to 8 o'clock.

SATURDAY, JULY 20.

The last excursion of the Convention of 1907 will leave Hereford train for Ledbury at 9.45. Here will be found many picturesque bean houses, a quaint market house (built in 1633) and a fine church, portions of which date from Norman and probably Saxon times.

The city of Hereford itself is particularly rich in subjects which appeal to all classes of photographers—architectural, archaeological, landscape, one of the chief, of course, being the cathedral, which Conventioners wearing their badge will be allowed to photograph at any time during the week, except when there is a service.

The Handbook contains a list of the hotels, boarding-houses, restaurants, etc., where accommodation may be obtained, also a list of photographic dealers and dark rooms in Hereford, Ludlow, and Shrewsbury.

## Exhibitions.

### KODAK PROFESSIONAL EXHIBITION.

It is now open, at the Portman Rooms, Baker Street, London, an exhibition of photographs and apparatus, brought together by the Kodak Company, and open from 10 a.m. to 10 p.m. to professional photographers and their friends. The photographs are, without exception, examples of portraiture by British and American photographers, and, while illustrative of the capacities of the various printing papers specially offered by the Kodak Company for personal use, yet present a variety of styles in posing, lighting, and printing, which no portrait photographer can fail to study without profit. We are glad to see represented on the walls examples of the work of Garo, Knapp, and other American professionals, who took part in the exhibition held at our own offices not long ago. The Kodak Co. have consistently done good service in keeping the name of this order in prominence, and the present collection will be found to contain not a few instances of professional photographers in this country having profited by the opportunities thus afforded.

The printing papers which make up the various panels are: collodion, sepia, cold bath platinum, ordinary platinum, "Velvet" solio, "Velvet" bromide, and Dekko and "Aristo" platino (collodion type). The last-named claims the lion's share of the space, and the panels devoted to it contain a great deal of magnificent work. It should be mentioned that demonstrations are given on a large scale of the "Aristo," solio, and bromide, and Dekko papers. In the room for the two latter will be found a very convenient printer, which permits of any size of negative being accommodated, and gives no light to escape. It is a very convenient professional printer.

The Aristo portrait lamps and the Aristo printing installation are shown working. In connection with the former, which is now adapted to work entirely by reflected light, note should be taken of two very useful screens, serving to cut off light, either from the front or upper portion of a sitter. In one case the screen is connected with a reflector, the two vigorous action of which it serves to moderate. The use of these screens is demonstrated.

The latest model of studio camera also on view includes a number of features which are commendable, including the rapid adjusting mechanism and the hood, to which gauze may be affixed as a ready means of modifying the lighting on the sitter and subduing portions which compete with the parts of chief interest. Numerous other accessories are on view, including a baby motor car, of which several studios are reported to make successful use as a tout, and a stand outside the establishment inducing the child to take a whimsical ride in it, and thus conveying him or her into the studio, to be worked by the mother. We must draw attention, too, to the drying exhibit and demonstration—Messrs. Kodak, Ltd., supply a line of adhesive tissues and machines, and the photographs on the walls are examples of their use—and to demonstrations of a new

air-brush, the "Airostyle," with an instantly removable needle, which is placed on the market at £4 4s. Demonstrations of "Negafake," the abrasion method of retouching, are also given. The whole exhibition, it will thus be seen, offers every inducement to professional photographers to pay it a visit before it closes to-morrow evening, at 10 p.m.

### THE GAMAGE EXHIBITION.

At Messrs. Gamage's huge and well organised emporium in Holborn there is now an exhibition of photographic apparatus, which is open free to the public daily from 9 a.m. to 8 p.m. (Saturdays 9 to 5). Among the exhibitors are Messrs B. J. Edwards and Co., whose stand displays a new plate "The Empire," just introduced chiefly for professional portraiture. Rapidity and fineness of grain are not the only features which are strong claims for its adoption. Messrs. Chas. Zimmermann and Co. show a new pocket folding focal-plane camera, as well as the standard patterns of Ernemann cameras, to which, we noticed, a very neat and efficient focussing hood is now fitted, as well as a finder, which automatically erects itself when the camera is opened, and *au contraire* subverts itself on the instrument being closed. These movements are two of the things to be seen at the exhibition. Messrs. Thomas Illingworth show a selection of their high-class enlargements and give demonstrations of Zigo self-toning papers. The Adhesive Dry Mounting Company have an attractive exhibit of their process, and the Standa Development Co. shows the latest patterns of the developing apparatus of that name, and offers to develop plates brought to it during the hours of the exhibition. Among other exhibitors are Messrs. Rotary Photographic Co., W. Butcher and Sons, Chas. Tyler and England Bros., Houghtons, Limited, Leto Photo Materials Co., L. Kamm and Co., Midland Camera Co., Theobald, and J. E. Lockyer, in addition, of course, to Messrs Gamage themselves, at whose stall everything photographic may be purchased. The exhibition, which is enlivened with music, remains open until June 8.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been received between May 6 and May 11:—

The following applications for patents was made between May 13 and May 18:—

**FILMS.**—No. 11,105. Improvements in and relating to means for removing sections of photographic films from roll and film cartridges and the like. Percy Albert Craven, 11, Maiden Lane, London.

**COLOUR PHOTOGRAPHY.**—No. 11,442. Colour photography. Ernest Braunn, 86, Hart Street, Southport.

**ENLARGING.**—No. 11,499. Improvements in and relating to lanterns and apparatus for enlarging purposes. William Frederick Butcher, 322, High Holborn, London.

**MEASURES.**—No. 11,507. Improvements in measuring glasses for dark-room purposes. William Frederick Butcher, 322, High Holborn, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**PLATE-CHANGER FOR COLOUR PHOTOGRAPHY.**—No. 11,986. The invention consists of a dark slide holding a series of three plates each in a sheath or carrier, which also contains the light filter. The slide is inserted in the camera in the ordinary way, and on the shutter being withdrawn the first plate is exposed *in situ*. This and the second plate are then caused to fall forward into the camera in such a way that they are out of the field of view. They are drawn again into the slide, when all three exposures have

been made. The mechanism for effecting the movement of the carriers is somewhat intricate, and consists, according to the first claim, of a pneumatic stopping and releasing means, comprising a plate and stem adapted to actuate a two-armed lever and a one-armed lever, which both carry a detent, the mechanism being so arranged that when the pneumatic bulb is actuated, the detent on the former lever is raised to release the foremost plate-carrier, while the detent on the latter lever is depressed to prevent the release of the second plate-carrier. Albert Müller, Linkstrasse, 13, Berlin, W., Germany.

**TWO SUBJECTS AT ONE EXPOSURE.**—No. 9,648, 1906. The invention consists of a small auxiliary camera consisting of a box, 1, containing a lens, 3, and opposite the latter a picture or design, 6, which is illuminated by an electric lamp, 11, in the box. The

object of the invention is to take at the same moment a single negative, the upper part of which contains the portrait of a person, and the lower a reproduction of some drawing or object. Herbert Oscar Seaman, Athlone, Victoria Road, Stetchford, Worcestershire, and John Edward Rickards, 3, George Street, Birmingham.

**VIEWING LIPPMANN PHOTOGRAPHS.**—No. 32, 1907. The invention consists of a method of viewing the Lippmann interference colour photographs, in which the reproducing lens system, or at least part of it adjacent to the photograph is simultaneously made use of as the illuminating lens system. Thus the angle of incidence, under which the illuminating rays meet the photograph, can be greatly reduced, by bringing the entrance pupil near the axis of the lens system, and further the photograph can be placed at right angles to this axis.

In order that light may impinge on the whole surface of the photograph in a uniform manner, the entrance pupil has to be arranged in the focal plane of the illuminating system. The principal rays proceeding from the centre of the pupil in that case impinge upon the photograph parallel to one another.

In order to prevent the catadioptric images of the entrance pupil, which are produced by the lens surfaces, from being projected upon the dioptric image of the photograph, the axis of the reproducing lens system may be arranged on one side of the photograph, but always perpendicular to it. The lens system is in that case used eccentrically. If this system consist of a single plano-convex piece of a lens, it may be cemented upon the photograph as a cover glass. It stands then at the same time in the place of the wedge-shaped cover glass, which is usually supplied in the case of Lippmann photographs to remove the disturbing surface reflection.

Two appliances for the production of a virtual image can be combined to form a double apparatus for viewing two identical or two stereoscopic pictures. The apparatus designed for a single picture can, however, also be arranged so as to use both eyes. Two entrance pupils are then best arranged for the light, one on the left for the entrance of the rays, which are to be reflected from the photograph into the right eye, and a right one for light which after reflection at the photograph is to render the virtual image visible to the left eye.

Fig. 1 is a diagrammatic plan view of an apparatus for producing a virtual image by a Lippmann photograph to be viewed with one eye. The image  $b^1$  of the entrance pupil  $b$  projected by the mirror  $a$  is situated at the focal distance of the lens  $c$ , and is

reproduced from this and from the photograph  $d$ , in as far as the picture-film reflects like a plane mirror, at the position of the eye  $e$ . The reproducing pencils produce simultaneously a virtual

image  $d^1$  of the photograph  $d$  behind the hinder surface of the photograph. There are no means provided in this simple example to abolish the catadioptric images of the entrance pupil, the axis of the lens  $c$  passing right across the photograph  $d$ . The latter is provided only with a plano-parallel cover glass  $d^0$ . Carl Zeiss Works, Jena, Germany.

**AUTOMATIC ENLARGING APPARATUS.**—No. 11,620, 1906. The invention consists of various means and mechanism for rapidly bringing the lens, negative, and sensitive paper into their proper relative positions.

The easel is so arranged as to be adapted to slide along the base-board or base of the apparatus in the usual or any suitable manner, and from the lower part of the easel a bar or slide of wood or other suitable material of graduated width is fixedly mounted on the easel so as to project towards the lens-carrier and negative-carrier and towards and away from which latter the bar or slide moves with the easel, one edge of this bar or slide being formed with a cam or so curved as to produce the automatic focussing as follows:—

A spring-controlled bell-crank or the like lever is pivoted to a support on the base or otherwise supported on the base; one arm of this bell-crank being adapted to bear (through the medium of any suitable anti-friction device such as a roller) against the curved or cam-like surface of the bar or slide against which it is kept constantly pressed by any suitable means, such as a coiled spring, while the other arm of this bell-crank (which is located in a different horizontal plane to the first-named arm—so as to be clear of the curved bar) is connected, by a connecting rod to the lens-carrier, the length of the arms of the bell-crank either being the same or different, in which latter case they are so proportioned that acting in conjunction with the curvature of the edge of bar or slide thereby the lens carrier will be moved at a differential speed towards or away from the easel as and when the latter is moved by hand towards and away from the lens-carrier so that the relative distances of the lens from the negative carrier will be correctly maintained throughout to produce automatic focussing in all positions of the said parts.

2. In place of the curved bar fixed on the easel and sliding with it as aforesaid—the second method consists in the employment of a specially curved swinging cam which is pivoted to the base-board or base of the apparatus and provided with a crank handle or other means by which the cam can be swung or partially rotated around its pivot, the easel being attached by suitable means such as a connecting rod to a crank on the cam or to the crank handle while the lens-carrier is kept normally pressed against the curved part of the cam, so that when the cam is turned through part of a revolution by means of its handle correct relative movement will take place of the lens-carrier and the easel, and thus in all positions automatic focussing will be produced.

3. Instead of the foregoing arrangements the automatic focussing may be obtained by means of a cam or curved surface fixed, formed, or carried on a pivoted lever, one end of which lever is connected by a rod or otherwise suitably connected to the lens-carrier, and the other end forms a handle, while the easel is connected through a connecting-rod or flexible connection to one end of a bent lever or bell-crank pivoted to the base-board, the other end of the bent lever or bell-crank being caused by a spring to bear against the curved surface or cam-like surface on the first-named handle lever, the arrangement being such that as the handle lever is operated the cam surface or curved

plate will be moved away from the end of the bent lever or bell-crank bearing against same, and thus permit the spring to draw the easel towards the lens carrier, the latter being moved towards the easel by the hand-lever in exactly correct relative speed to produce automatic focussing at all positions of the parts.

The twelve figures of the mechanism are required for a proper explanation of it. Houghtons, Limited, 88 and 89, High Holborn, London, and James Wright Craig, 88, Braid Road, Edinburgh.

### New Trade Name.

ICE, A SIGNBOARD BEARING THE LETTER N.—No. 291,997. Photographic films and plates included in Class 1. Houghtons Limited, 88 and 89, High Holborn, London, photographic manufacturers. April 10, 1907.

### Analecta.

Extracts from our English weekly and monthly contemporaries.

#### The Pocket Camera.

There has been for some time past (writes Mr. W. Thomas in the *Amateur Photographer*) a tendency to provide a small form of camera, which should not be too bulky for carrying about, and giving a picture something less in size than the quarter-plate. Several such cameras, using plates of  $3\frac{1}{2} \times 2\frac{1}{4}$  have been placed on the English market, each of which, in proves very satisfactory, some being fitted with focal-plane shutters, others having the ordinary shutter attached to lens; both, for their special purposes, are good. Quite one of the latest introductions is the "Sybil," made by Newman and Guardia. It is up like a cigar-case, is ready at a moment's notice, works with perfect smoothness, has a lens aperture of  $f/6.5$ , a shutter speeds range from  $\frac{1}{4}$  to 1-100th of a second, and seem really to pretend it to be; is made entirely of metal (except the screws), has no complicated movements to worry over, is an immense pleasure to use, and produces exceedingly good negatives.

#### Markings on Negatives.

An editorial in "The Photographic News" of May 24 deals with the case in which disagreeable opalescent markings were produced by drying negatives hurriedly with methylated spirit. In the case mentioned it was found that if a negative were hurried through the processes of fixing, washing, and drying with spirit these markings were very likely to put in an appearance. At first it was thought that the impurities in the commercial methylated spirit coming into contact with the water in the film was the cause; but as seen that pure spirit had also the same effect. The photographer, in his praiseworthy haste to get the negatives through quickly, waited only until the visible creaminess had disappeared from the film, then gave a quick rinse under the tap, and treated them with methylated spirit. As the film dried the markings grew apace. Application of water—i.e., a further washing—removed them, they appeared again when the plate dried, and not until the plate was treated to another period in the fixing-bath, followed by a good wash, did the marks disappear.

#### The Value of Backing.

It is a common idea of the inexperienced (writes Mr. A. Lockett in "Focus") that backing makes very little difference except for faint subjects. As a matter of fact, there are very few subjects possessing any brightness or vigour of lighting which are not improved by backing—in the majority of cases greatly improved. In a where there is no chance of actual halation being present, crispness and clearness of the negative is almost sure to be needed. To sum up, it may be said that—barring some very exceptional occasions when a slight halation may be pictorially a detriment—none but backed plates should ever be used by those who wish to obtain the best possible results. The slight extra expense involved is always amply repaid.

## New Books.

"The Photographic Red Book." London: The Affiliation of Photographic Societies.

The Affiliation of Photographic Societies' annual for 1907-8 has reached us, and presents much the same appearance as in previous years, its enlarged form being still maintained by the inclusion of twelve half-price tickets of admission to the exhibition of the Royal Photographic Society which opens in September next. The book sets forth the advantages accruing to affiliated societies, together with their rules and management, and also the benefits and privileges conferred on their members individually. The list of "places to photograph," with full instructions for obtaining permission for the same, is not highly instructive, and might be cut down with advantage. A list is also given of affiliated societies, both in London and the provinces, including the names and addresses of their officers and headquarters, dark room accommodation, etc., which will prove serviceable to the tourist and holiday maker; whilst the inclusion of a table of distances, enlarging, and reducing formulae, speed numbers of bromide papers, and other useful items of information are commendable features.

THE "BIBLIOTHECA CHEMICO-MATHEMATICA."—The price current of old and rare books, issued by Messrs. Sotheran and Co., 140, Strand, W.C., reaches our table. It contains works by authors, arranged alphabetically from G to H, among whom we find Robert Hunt, both editions of whose rare "Researches on Light" Messrs. Sotheran can supply. Another interesting photographic entry is the "Chemical Handicraft," of John J. Griffin, issued in 1866, and the "Chemical Recreations" of the same founder of the present Kingsway firm of Velox fame, which first saw the light in 1838.

"EVERYBODY'S GUIDE TO PHOTOGRAPHY."—A new edition of this popular sixpenny guide reaches us from Messrs. Madgwick Hulston and Co., Ltd., 4, Ave Maria Lane, E.C. The author, Mr. E. Pierce, accomplishes his task of initiating the beginner very satisfactorily, on the whole, and is everywhere very explicit. One may wish for less misleading passages in one or two instances in the chapter on optics, but on the whole the volume is accurate, if all too brief.

## New Materials.

PAGE-CROFT POSTCARDS.—The new self-toning paper of Mr. Page-Croft, Cooksey Road, Birmingham, is now issued in postcards of assorted tints. The cards are tastefully produced, with rough edges (gilt), and are supplied in sixpenny and shilling packets, complete with masks. A sample packet will be sent on receipt of two stamps.

ROYAL PHOTOGRAPHIC SOCIETY.—It has been arranged to abandon the technical meeting formerly held on the fourth Tuesday in June and to substitute for it a practical demonstration on the first Tuesday in that month. A meeting is now held at the Society's House on every Tuesday evening from the first Tuesday in November till the second Tuesday in June, inclusive, except upon those Tuesdays which follow immediately after a public holiday.

"TOURS IN GALLOWAY" is the title of the official guide-book to South-Western Scotland, issued by the Portpatrick and Wigtownshire Joint Railways, and intending visitors to the picturesque holiday land cannot do better than obtain a copy. It contains copious, well-illustrated notes on the chief places of interest to be met with whilst touring in the locality, together with a list of hotels, apartments, farmhouses, etc., at the various stopping places where accommodation suited to all classes of visitors can be obtained. Particulars of travelling arrangements, circular tours, etc., are also given, and in fact all the information required by the average tourist in this part of Scotland. A copy of the guide may be obtained by sending two penny stamps to the Traffic Manager, Portpatrick and Wigtownshire Railway, Stranraer, N.B.

Fig. 1.

No. 19 "secto" taking 3 on  $\frac{1}{4}$ -plate.No. 4 "secto" taking 12 on  $\frac{1}{4}$ -plate.

## New Apparatus.

The "Multisecto" Repeating and Midget Apparatus Sold by Jonathan Fallowfield, 146, Charing Cross Road, London, W.

In this piece of apparatus, which has just been placed upon the market by the firm of Fallowfield, there are embodied facilities which every professional maker of the smaller sizes of portrait photograph must have wished for many a time, that is to say the attachment allows of a very great range of sizes being obtained, and further, it dispenses with the use of odd-sized plates; all its work being done on either the half or quarter plate. These two facts should entitle the "Multisecto" to the interested examination of any midget photographer, who, unless we are mistaken, will find it a piece of apparatus which realises all that he has desired in such an accessory.

The "Multisecto" consists of two parts, a back, which is supplied in a form readily fitted to almost any make of camera of the square whole-plate pattern, and a dark slide which differs from those of the ordinary kind only in the arrangement of removable slotted bars, seen to the right in the drawing. In the majority of cases the work of fitting the back is very slight and entails no alteration to the camera. The accessory is removed in a few seconds and the camera is then at liberty for ordinary work.

Fig. 4.

Figs. 2 and 3.

The method will be understood from a glance at Fig. 1, in which it will be seen that the back carries a mask, or "secto," with three apertures and the corner cut off (Figs. 2 and 3.) The particular disposition of the "secto" decides the number of pictures on a plate, and when a given one has been inserted all that is needed is to attach the corresponding slotted bar (Fig. 4) to the dark slide and make the exposures row by row on the plate, the "secto" being moved between each row. As a result of this simple process no less than twenty different sizes of pictures may be obtained on the two popular sizes of plates, from one  $1\frac{1}{3} \times \frac{4}{5}$  (15 on the quarter-plate) to the quite respectable size of  $3 \times 2$ , three of which are obtained on a half-plate. It is particularly in the larger sizes that the apparatus will be found welcome by the professional photographer, as it gives him the choice of some very pleasing shapes and sizes, in addition to the smaller ones usual in button work. We illustrate on this page two of the arrangements out of the total twenty, commending the apparatus to the attention of those—and we believe them to be an increasing number—who have acceded to popular demands in providing midget portraits. The complete "Multisecto" is sold at 50s., at which price are included the twenty "sectos" and slotted bars for the dark slides.

point which should not be omitted in reviewing this very accessory is that Messrs. Fallowfields are issuing a special series of "Multisecto" mounts for each size, so that there be no need for a photographer, doing an extensive business apparatus, to fill his window with a confusing assortment of mounts. The adoption of a single style will give character to work, and will still further emphasise the commercial advantage of the apparatus.

ket Stereoscope. Sold by the Stereoscopic Postcard Company, Limited, Essex House, Stratford, London, E.

stereoscope in question forms part of the policy of the Stereoscopic Postcard Company to supply stereoscopic views and viewing apparatus at popular prices. It is of cardboard covered in velvet, answers its purpose sufficiently well, and costs but 9d. a figure which yet allows a profitable discount to the trade. The firm also supplies the usual wood and aluminium hooded stereoscopes.

series of stereoscopic postcards of the regulation size of 5½ in. in. embraces a wide range of subjects, the photographic character of which, judging from the examples sent to us, is good. Cards retail at 2d. each. A hand-coloured card, also photographic, is supplied at 3d.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, JUNE 1.

Photo Art Club. Outing to Speyside (Aberlour).  
and District Photographic Society. Outing to Oxshott.

#### THURSDAY, JUNE 6.

and Provincial Photographic Association. Open Night.

### ROYAL PHOTOGRAPHIC SOCIETY.

ng held 28th inst., Mr. E. J. Wall in the chair. A paper by E. Kenneth Mees and Mr. J. K. Baker on "The Measurement of Efficiency of Dark Room Filters," was read by Dr. Mees. Referring to the visual luminosity curve of the spectrum, the authors pointed out that the greatest value lay in the green, especially at intensities, and by cutting out the red and blue it was possible to use safe lights, which were agreeable to the eye, and were yet equally without action on the plate. The results of their measurements, however, had been to convince them that absolute safety and efficiency was a combination which it was practically impossible to attain in practice, and they had been convinced of the wisdom of the brown maximum, to shield the plate as much as possible from the room light. The measurement of the intensity of the light given by different filters was made by attaching a black cross, made by pieces of lantern slide binder, to the filter, placed in the lamp. The cross was focussed on the ground glass of the camera, the lens of which was gradually stopped down until the cross became invisible on the ground glass. This extinction method was not very accurate—varying from 25 to 40 per cent.—but it gave a fairly good idea of the widely differing intensities of the different filters. Different

observers would make very different measurements, but the ratios were about the same. As a standard of safety they took a filter, which at one metre distant from the plate and with an eight-candle power lamp behind it, produced no fog in half a minute, but produced fog in one minute. This corresponded to a number 50 in the table given for the safety of the different lights. The authors gave particulars of the dyes used in making filters suitable for slow ordinary, rapid ordinary, isochromatic and panchromatic plates.

In the subsequent discussion Dr. Mees, in replying to questions, said that he usually bound up the glasses forming the filter, but did not cement them. He could not see that liquid cells had any advantage over the solid screen. A grey screen, which Mr. Hector Maclean thought would be of service as a dark room filter, was obviously of no use for that purpose. The sensitiveness of a plate did not alter very greatly. Dr. Mees thought, on being wetted with the developer, it became about halved. All their tests had been made with plates in the dry state, inasmuch as plates were in that condition when first manipulated in the dark room. Mr. C. Sordes Ellis thought that a light of greater intensity than those mentioned in the paper was permissible, from the fact that a plate could be slipped into the developer in the deep shadow of the lamp, and its sensitiveness having been thus depressed, might be exposed to a light which would be unsafe in the ordinary conditions. The chairman stated that he was accustomed to develop panchromatic red-sensitive plates at some six feet from an ordinary ruby lamp, but Dr. Mees thought the practice dangerous, and Mr. A. J. Newton instanced a case where, by exposing a red-sensitive plate to such a light, he got a positive instead of a negative.

At a late hour the secretary, Mr. J. McIntosh, demonstrated the results obtainable by the method of ammonia fixation and toning with ammonium sulphide applied to printing-out papers. A note on this subject appears in the current issue of "The Photographic Journal," and Mr. McIntosh's demonstration showed the tones which were obtainable on two commercial brands of gelatine printing-out paper.

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—At Wednesday's meeting of this society at 75, High Street, Lewisham, new members were elected which brought the total up to 130, and further members were nominated. Mr. Chas. Stuart started a discussion on "picture-making," which resolved itself into a battle royal between the advocates of fuzziness and those who favoured  $f/6.4$ . Mr. Stuart, with the fervour of a recent convert, recommended the orthodox pictorial recipe—the main object sharp, and the rest fuzzy. Mr. Winney contended that a "sharp-all-over" picture more nearly represented nature as seen by the human eye, and showed some examples in which the planes were pretty well differentiated, in spite of their definition. Mr. T. K. Grant judiciously summed up the middle position, and pointed out that, while one man will get his emphasis by throwing part of the picture out of focus, another expert gets his by contrast of light and shade.

## Commercial & Legal Intelligence.

**ALLEGED ADVERTISEMENT FRAUDS.**—Thomas M'Hugh and William M'Hugh, father and son, were again before the Liverpool Police Court last week on a charge of obtaining money from assistants in the photographic business by false pretences, and with conspiring to defraud.

Mr. H. F. Neale represented the elder prisoner Thomas, and Mr. John Sefton appeared for William.

A young man named Robinson Hindle, who is a clerk, and lives in Heriot Street, gave evidence as to £100 he had parted with as a premium to the prisoner. He had answered an advertisement for an assistant wanted in the photographic business, and called at "Hugh Mack's" studio, 71, London Road. There he saw William M'Hugh, who told him that he wanted a reliable, steady, young man for his assistant, and asked what premium he was prepared to advance. After some bargaining he agreed to pay £100, and handed it over in the form of a Bank of England note. It was agreed that witness

should receive a weekly salary of 35s. and  $\frac{2}{3}$  per cent. of the profits, and remained in prisoner's service until the two were arrested. One day, about the middle of April, Thomas M'Hugh approached him with the object of securing a further advance of £150. That would make his deposit £250, and Thomas promised to lend him another £250 to make his share in the business £500. Witness asked him how he would pay back the £250, and Thomas told him that it would come out of the profits of the trade. "He also told me," added the witness, amidst much laughter, that "it was the chance of a lifetime." Thomas also stated that another young man wanted to put £500 in the business and become a partner, but he (Thomas) would not allow his son to take him, because he was a "boozer." Witness did not consent to make the further deposit.

In reply to Mr. Neale, witness agreed that the elder prisoner had taken no active part in the business.

James Stewart Galston, a musician, who had paid to William M'Hugh a premium of £10, was also in the box. To him William had represented that his father was a commercial traveller who had given him £1,000 to start business.

Albert Edward Harrison, a mechanic, belonging to Hull, who had advanced £10 towards £50 to be apprenticed to the photographic business, was the last witness called, and the stipendiary then remanded the accused, allowing the elder man bail as before.

## News and Notes.

**NEW FELLOWS OF THE R.P.S.**—The following six candidates for the Fellowship have been elected out of twelve who applied:—Donald Cameron-Swan, Robert Thorn Haines, Robert Laidlaw, F. C. Lambert, Oliver G. Pike, J. Watson.

**INVISIBLE PRINTING INKS.**—A correspondent writes:—"Some years ago I was shown some specimens of invisible sympathetic inks by Mr. Winston. If your correspondent applies to Fetter Lane it is quite likely they are still on the market."

**METHYLATED SPIRIT DRINKING.**—Being out of work, Robert Aspland Hatt, thirty, a Hackney photographer, took to drinking methylated spirits, and died from pneumonia accelerated by chronic alcoholism.

**DEATH FROM CHLORAL.**—A photographer named Timms, of Langley Mill, was found dead in his bed last week from the effects of an overdose of chloral, taken to induce sleep.

**MR. JOHN W. SMITH,** for some years manager for Mr. R. W. Paul, has severed his connection with that firm to join the Warwick Trading Co., as manager. Mr. Smith will be pleased to meet his friends in the trade at 4 and 5, Warwick Court, High Holborn, London, W.C.

**TOURIST LITERATURE.**—The official illustrated holiday guide of the London and South-Western Railway is again in hand in its usual attractive form, and is certainly one of the best books of the kind issued gratuitously. It contains notes on the chief places of interest reached by the company's rail and steamship services, together with numerous illustrations. Also, a list of hotels, boarding houses, etc., not the least interesting feature being the carefully revised and up-to-date list of golf links and clubs situated on or near the London and South-Western Railway system. The whole forms a well-arranged compendium of information, and may be obtained free of charge from Mr. Henry Holmes, Superintendent of the Line, Waterloo Station, London, S.E., or from any agent of the company in England or on the Continent.

**YORKSHIRE PHOTOGRAPHIC UNION.**—The annual excursion of members of the Union will take place on Saturday, June 22, Hull and Beverley being the places chosen for this year's gathering, and as both are rich in objects of photographic interest the outing should prove both pleasurable and profitable to all concerned. Tea will be provided at the rooms of the Hull Photographic Society, and particulars as to tickets, train arrangements, etc., may be obtained from Mr. Ezra Clough, 10, Farchliffe Road, Bradford.

**"THE EXPERT."**—The first number of the new weekly (Saturdays, 3d.) gives promise of its usefulness to the collector of old and

modern articles of art, vertu, furniture, and the like. "The Expert" makes liberal use of photographic illustration, and is generally produced and edited. The issue before us contains articles on:—Ham Hall; English Eighteenth Century Drinking Glasses; Lace; Book Plate Collecting; Church Gresley Ware; Collecting.

**"THE CAMERA HOUSE BEACON."**—We are glad to extend a welcome to a contemporary in Melbourne, Australia, which has commenced career under the above title. It is issued monthly by H. J. T. Bridge, 356, Colliers Street, Melbourne, under the editorship of J. Albi (J. O. Moerch).

**HARD LABOUR FOR TRAVELLING PHOTOGRAPHER.**—Walter Stenson, a young man, described as a travelling photographer, brought up at the Welshpool Petty Sessions, charged with stealing a Globe bicycle, valued at £4 the property of Mr. E. C. Bigg, cycle agent. On being formally charged prisoner elected to be tried with summarily and pleaded guilty. Superintendent Williams there were no previous convictions against the prisoner. This of people gave the police a lot of trouble. They came into the county with no intention of paying for their lodgings, and generally succeeded in taking something away with them. There were other cases of the kind in the county now. The Mayor, in sentencing prisoner to two months' imprisonment with hard labour, said occurrences were much too frequent in the district.

**THEFT BY TRAVELLING PHOTOGRAPHER.**—Frank Dudley, Rivers, a travelling photographer, was charged with obtaining a camera, value £27, by false pretences from Albert Perry, of Uttoxeter, on March 22. He at first denied the offence but afterwards admitted, and said that he had pawned it for £3 in London. He was remanded.

**PHOTOGRAPHY AND LITERATURE.**—An interesting series of outings with some literary interest has been arranged by the South Suburban Photographic Society. It is proposed to deal with the portion of Old Pilgrims' Road (from Winchester to Canterbury), which over the hills between Westerham and Maidstone. The first of the outings will be led by Mr. H. Snowden Ward (editor of the "Photographic Monthly") on Saturday, June 8, with Wrotham as rendezvous. There is a fine old church at Wrotham, and some picturesque views may be had in the neighbourhood. On Thursday, June 13, Mr. J. T. Ashby leads another outing to Knockholt, via the Old Pilgrims' Way runs by Hogbrough Hill. The last of the series will have Maidstone for centre, and will probably have Snowden Ward again for leader, about July 27. Mr. Ward, who has written "The Canterbury Pilgrimages" was recently published, made a special study of the subject, and the society is fortunate in securing his co-operation. Mr. Ward Muir and Mr. and Mrs. C. Cadby all live in the neighbourhood of Wrotham, and it is hoped they will be able to join the party. We understand that visitors from other clubs and societies interested will be welcomed. The hon. secretary of the society is Mr. J. Nixon, of Ingleside, Chislehurst, Blackheath.

**PALACE THEATRE.**—At the invitation of the directors of the Palace Theatre a company of pressmen and friends on Monday last visited this renowned place of entertainment, to inspect recent alterations and improvements. The management have remodelled the bioscope chamber, which contributes largely to the Palace programme, the result of securing an even steadier picture on the screen, making assurance doubly sure as regards the safety of the theatre. In many other respects the comfort and entertainment of the visitors have been further studied. The lighting arrangements before the curtain have been overhauled, and the accommodation in the stalls made the height of convenience and luxury. The Palace justly prides itself on the coolness and safety of the building, its island site permits seven exits on the ground floor—and it is satisfactory that its accommodation is made fully worthy of the refreshment to be witnessed on its stage.

**PAGET PRINTING PAPERS.**—Visitors to London may be interested in noting the remarkably fine display of prints on the "Simplex" and other papers which now occupies the window of Messrs. Houghtons, Ltd., 88-89, High Holborn, W.C.

## Correspondence.

Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

We do not undertake responsibility for the opinions expressed by our correspondents.

### A WAVE OF ORTHOCHROMATISM.

To the Editors.

men,—“A Colour Painter” will have seen from the third of my letter of last week that I have not been “misled by bogey of luminosity values,” and I must express regret if biguity on my part should have created such an impression. I will forgive me if I leave any discussion on the fresh raised to others more competent to deal with it. It is by no means new, and has been very energetically controverted in the

doubt “colour luminosities” must be falsified occasionally. The simple case of red poppies in green grass. Both may have the same “luminosity value,” and probably the best rendering of the red (being a more advancing colour), of the green than the surrounding green. Such cases are, however, only in the nature of a compromise, and must be sharply distinguished from the enunciation of a principle that “colour values,” *per se*, can be translated into monochrome. Such translation I firmly believe, would in each instance vary, and vary with the temperament and colour perception of the artist. I have never been able to learn from painters exactly what they do want in this connection, and very much doubt whether they know themselves. “A Colour Painter,” however, combines with the “lesser arts”; perhaps he can state some definite principle for our guidance.—Yours faithfully,  
E. A. SALT.

### BLUE PAPERS AND OTHER MATTERS.

To the Editors.

men,—History repeats itself. Some short time ago there was a controversy in regard to how to know when a blue print (on ussate paper) was sufficiently exposed to be washed. A question of some kind was demanded—a photometer. Then came a letter from a Mr. X. that his paper needed no such arrangement. Thirty years ago I used, made, and sold ferro-prussiate and the exposure could be seen as well as now, and the process was easy to follow, viz., Look at the print, and when it just begins to change colour on the lines which were to be white after washing, then the print is ready to be washed. The difference now, in the making of the paper, to change the colour? Is it not always ferricyanide and citrate, proportions required?

page 396 of the “Journal,” exposure for architectural sub-photometers of all kinds have been invented, and yet the same is brought out which was good enough thirty years ago. It remains true to date, and was published by myself at that time:

interiors (and exteriors, for that matter) the only reliable method is that of experience.

again: The exposure should be for the shadows; the highlights take care of themselves. True to date.

news No. 3,347, 1907, is splendid. This is good as long as the housebreaker has not read about it. Next he will put his finger on the opening of the lens (of very short focus, subject being to 15 in. from it), and explode the light first and work it, or maybe stand aside first to cover his face with a rag and, or—or— Splendid and useful invention, unfortunately like many others.

ill the landlord open his door himself and close it when he is ready. Rather complicated machinery to remain unseen!—Yours  
A. LEVY.

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to “THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C.” Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.

\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

C. Treasurer, 21, Inglis Street, Inverness, Scotland. Three Photographs of the Rev. Murdo MacKenzie.

W. Marshall, 31, Hart Street, Henley-on-Thames. Two Combination Photographs of Five Views taken at Henley-on-Thames.

BOOK ON OPTICS.—Will you kindly give publisher's name and price of Lummer's book, mentioned p. 399, current issue?—M. C. Macmillan and Co., Ltd. Price 6s.

PHOTOGRAPHY IN PARIS.—I should be pleased if you could inform me if snap-shooting (hand or stand camera) is allowed in Paris, or is permission necessary?—FRANCE.

As in London, so far as all exterior views and scenes are concerned. For interiors the usual permissions are needed.

MILANO.—For the sepias, bleach in:

Ammonium bromide .....	35 gms.
Potass ferricyanide .....	35 gms.
Water .....	1000 ccs.
and after a brief wash, darken in:	
Sodium sulphide (pure) .....	12 gms.
Water .....	1000 ccs.

It is not easy to obtain a satisfactory blue tone, but the following is as good as any. The prints must be pale, as the process intensifies them:—

10 per cent. ferric ammonium citrate solution...	10 ccs.
10 per cent. potass ferricyanide solution .....	10 ccs.
10 per cent. acetic acid solution .....	100 ccs.

A very good blue toner is made by Messrs. A. and M. Zimmermann, 3, Lloyd's Avenue, London, E.C.

W. W. (Lausanne).—The addresses asked for are:—James Swift and Son, 81, Tottenham Court Road, London, W.C.; and George Hare, 26, Calthorpe Street, London, W.C.

KILLING FORKIES.—Would you kindly inform me if there is anything I could get to kill forkies? My studio is built of wood, on the ground, and last summer I was over-run with these pests, creeping about the studio in all directions.—G. G. G.

We are quite unable to assist you. As a matter of fact, we do not know what “forkies” are, and no dictionary we possess enlightens us in the matter. Neither can any friend whom we have asked; all say they have never heard of such things. You say your studio is built of wood on the ground, and possibly this is a garden pest indigenous to north countries, in which case a horticulturist in your neighbourhood could probably tell you how to exterminate the pests.

OBSCURING GLASS.—I am desirous of making some imitation of frosted glass on the outside of a window, and should be glad to learn your opinion on the use of white paint or water-glass solution, mixed with chalk, to be dabbed on, much as is done with

ordinary whitening mixture on the windows of empty houses, etc. The idea is, of course, that my imitation frosting—as it is to be exposed to all weathers—must be waterproof, etc.—G. BARNARD.

If ordinary white paint be used there is no necessity to add chalk to it. Usually the frosting is done on the inside of the glass, where, as a matter of course, it is more durable than it would be on the outside. There are silicate paints sold, but whether they resist the weather better than oil paints do we cannot say, as we have had no experience with them, as applied to the outside of glass. We should certainly recommend you to stipple the paint on the inside, whatever you use.

**BUTTON PHOTOGRAPHS.**—I shall be glad if you can give me some practical information respecting miniatures. I secured colour and booklet from Fallowfield. My difficulty lies in fixing celluloid to face of print with hot roller. I soak in alcohol as directed, but as soon as I apply warm roller the celluloid becomes clouded or else will not adhere. I am a constant subscriber to your valuable paper, and shall be obliged if you can give the necessary information for the making of successful miniatures.—**PERPLEXED.**

If you have a proper roller and plate, and follow the instructions supplied with it, we cannot see how you should fail. The thing is so simple. The print only should be soaked in strong spirit, the celluloid laid on it, and the heated roller passed over it two or three times, slowly; perfect adhesion is then secured. Probably you have not allowed the roller to become sufficiently heated. It should be as hot as the hand can well bear.

**THREE-COLOUR WORK.**—I have been trying a little three-colour work, with very poor success. It has struck me that if I used a Kodak camera with films I should have the advantage that there would be no risk of light fog in loading, and I could afterwards develop them all at once in a tank. Can you tell me if there are isochromatic films made sensitive enough for this work, also whether Edwards' iso. plates would give good results if one gave a long exposure for the red screen? I am using Dr. Miethe's screens.—G. A. COLLINSON.

There is no panchromatic film made, but any of the ordinary orthochromatic films, as also Edwards' iso. plates, would answer, provided the ratio of the filters was altered. Miethe's filters practically divide the spectrum at  $\lambda$  400—490 for the blue-violet, 490—589 for the green, and 589—700 for the red sensation. Now nearly all the ortho. plates have a minimum of sensitiveness in the green-blue, therefore the exposure under the green filter must be prolonged, in order to give this time to fill up. As the sensitiveness of these plates to red is practically nil, it would be necessary considerably to prolong the exposure through the red screen. In the case of outdoor work and portraits, this would not be much disadvantage, as pure reds are rarely met with in Nature, but for copying coloured objects and still life, where pure reds are more often met with, it would be a great disadvantage.

**R. ATHERTON.**—We are unable to trace the paragraph. An etching ink is sold as Sabatier's by chemical apparatus houses, such as Baird and Tatlock, Cross Street, Hatton Garden, W.C. Perhaps this is what you require.

**DEVELOPING P.O.P.**—Would you kindly assist me in the following? In the issue of the Journal, October 20, 1905, a formula was given for developing P.O.P. by Dr. Woolsey Blacklock. I tried it at the time and obtained satisfactory results. This last week I have again tried it, and it will not give the results without toning the prints. Can you tell me why? The formula I have followed faithfully. I believe, though, that there was, in a closely following number of the "B.J.," a comment upon it, and possibly I used that formula instead. Can you look up the number in question? I want a formula to develop P.O.P. without having to tone the prints.—**PUZZLED.**

The comment was in issue of November 3, 1905 (see "B.J. Almanac," 1907, page 782). A little 5 per cent. solution of silver nitrate was added to the developer. You will see a variety of other formulæ in the "Almanac," pp. 780-784. We fear you will not get results which dispense with gold toning.

**W. WHITE.**—Professionals are estimated at from 8,000 to 10,000. Of

amateurs, there are no data. The following are the periodicals: "Photo-Revue," 118, Rue d'Assas, Paris; and "Revue de Photographie," 44, Rue des Mathurins, Paris; "Das Atte," "Photographisches Chronik," both from W. Knapp, Halle, Germany; "St. Louis and Canadian Photographer," 3, 210 St. Louis, Mo., U.S.A.; and "Shacin-Shimpo," 10, Ch. Kobikicho, Tokio. You will find others in the list on page of the "Almanac."

**OLD FOGGY.**—The card is undoubtedly photographic, and appears a gelatine P.O.P.

**GLAZING P.O.P.**—I shall be glad if you can tell me any way of glazing P.O.P. postcards besides putting on to glass or on type. I believe there is some special way in which some of the postcards now on the market are treated. Unless we first strip the cards we find them inclined to stick, and as this is waiting, I shall be glad to hear of a different method, if it is one.—K. R.

Stripping from glass is the regular commercial method. Prints are usually given ten minutes or so in a bath of  $\text{H}_2\text{O}_2$ . A good deal depends upon the proper polishing of the glasses with French chalk. The glasses improve, as regards easy stripping, with use.

**POSTCARDS.**—During the past few years I have taken a series of views in this town, most of which I have produced as postcards which have had a fairly good sale. I am now anxious to get your advice in the following matter. Yesterday I accidentally came into possession of a box of sweets on the cover of which reproduced one of the views above mentioned. The box bore the name of a confectioner in this town, and also of the makers of the sweets—or, perhaps, of the boxes; I cannot say which, as are unknown to me. I shall value your opinion as to whether the guilty party, and what I should do.—**MERLIN.**

It is possible that both have acted innocently; but, having registered the copyright in the photograph or photographs, can take action against either the confectioner or the photographer who can be proved to have supplied him, but such action only apply to infringement committed after the registration. We should advise you to write a note to the parties asking for a reasonable settlement they can suggest.

**S. C. P.**—Better apply to the secretary of the Professional Photographers' Association, 89, Albany Street, N.W.

**VOLATILE SOLVENT FOR GELATINE.**—Is there any volatile solvent which will dissolve gelatine (like water) without altering its general properties? My idea is to secure more rapid drying of a print after coating with gelatine, than is possible when the ordinary aqueous solution is used.—**MARCO.**

The only possible thing to do is to dissolve the gelatine in glacial acetic acid and then gradually add alcohol. A perfectly clear solution can be obtained which will sometimes dry but not always, this depending upon the gelatine used. When the acid would act on any substance which is to be used with the gelatine we cannot of course say, as our querist gives no idea of what the plate is required for.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

hibition of reflex cameras and of photographs illustrating utilities opens at the "B.J." house on Thursday next.

J. Anderson, in some further notes on the efficiency of states the requirements of the pictorial photographer.

re of orthochromatism. Mr. W. Thomas pictures the of the "ordinary" plate as a guest at dinner who declines and the cigars. (P. 426.) paragraphs on the same question appear on pages 429

week's correspondence a reader in the Malay States writes nematograph shows in the East, Mr. Nelson K. Cherrill has tion for the prevention of blisters in bromide paper, and reader complains of dark-room anæmia. (P. 474.)

E. Sheppard reviews the sensitometric methods of Mr. Wallace. (P. 426.) ll text of Mr. Wallace's paper is concluded on page 427.

llected researches of Drs. Mees and Sheppard have been by Longmans. (P. 431.)

## "COLOUR-PHOTOGRAPHY" SUPPLEMENT.

C. Tilney, whilst recognising the enormous possibilities of al colour-printing laments its present æsthetic standard.

ciety of Colour Photographers announce an open exhibi- e held in London in the autumn. (P. 46.)

lified method of pinatype has been published by M. Leon (P. 43.)

and theories bearing on the relation of fluorescence to ensitising are discussed by Herr J. Stark and Mr. E. J. (P. 44.)

ests for lenses to be used for colour work are given in an a page 42.

## EX CATHEDRA.

**The Reflex Exhibition.** We repeat elsewhere in this issue the particulars of the exhibition of reflex cameras which will be opened at the house of the "B.J." on Thursday next, at 10.30. To the firms already announced we have to add the name of

Taylor, Taylor, and Hobson, Ltd.,

who will show for the first time a reflex camera of their manufacture, in which great portability has been obtained, and in which a metal frame construction is adopted on the score of durability and lightness. We would once again remind our readers that the exhibition is open without charge until July 6, between the hours of 10.30 and 4.30, except Saturdays, when it closes at 12.30. Next week we shall deal fully with the exhibits, and in this and following issues shall publish several articles specially bearing on the facilities offered by cameras of the reflex type.

\* \* \*

## Canvas Effects.

A correspondent who addresses us for advice on the selection of some medium able to give him a complete change from the matt surface of printing papers, may very justly be recommended to look back to our notes of May 24 on the canvas bromide lately introduced by Messrs. Wellington and Ward. Our inquirer is not alone in his failure to recognise in this new material not merely another variety of surface, but a clever combination of a woven material and paper. It is not only in surface, but in toughness as well, that the new canvas bromide attains distinction, and the results obtainable with it are deserving of all the recommendation we can give them in the eyes of our professional friends who desire a print both rapidly producible and effective, and, as in the present instance, exactly what it pretends to be.

\* \* \*

## The R.P.S. Exhibition.

The prospectus of the forthcoming annual exhibition of the Royal Photographic Society—the fifty-second—has been issued, and shows that the Society has arranged to make no departures from its existing regulations. As before, Class III., "Professional and Commercial Photography," is to be a section space in which is bought and paid for by the exhibitor. The system has evidently proved satisfactory to the degree which silences criticism, much as we should like to see the exhibition management taking an interest other than a financial one in professional photography. Professionals, however, compete on equal terms with amateurs in the "pictorial" class, and will, we hope, take advantage of the opportunity in their numbers. The prospectus of the exhibition is obtainable free from the Secretary of the Royal Photographic Society, 66, Russell Square, W.C.

**Exhibition Standards.**

The considerations which have led judges to make their awards at photographic exhibitions must often excite the curiosity of the exhibitor, both recognised and unrecognised, and he may be sometimes excused for harbouring a doubt of the existence of any definite opinions as to what is good and bad in the minds of the jury. Not infrequently an explanation of an award to a picture devoid of any particular merit may be obtained from the supposition—founded on fact—that the judges were divided between two exhibits, and, in default of being able to agree, gave the award to something which was worse than either. It is therefore of interest to quote what appears to us as a useful epitome of the factors to be considered in the judging of photographs, which we find embodied in the report of the judges of the Wyoming Valley Camera Club, U.S.A. The opinions are those of Mr. Arthur W. Bow, art director of Teachers' College, Columbia University.

A photograph which is merely a record of fact, is in no sense a work of art. It has, if accurate, a scientific, historic value, but not an artistic value. The art lies in fine relations of line, and beauty of tone—or beauty of proportion, and beauty of massing. And these qualities must be deliberately planned by the author.

**Subject.**—Almost anything will be interesting if expressed in art-form, i.e., in terms of beautiful line, and dark-and-light. Success in choice of subject depends upon seeing the possibilities of harmony in these terms.

**Composition.**—First, choice of a size and proportion to fit the subject. Then, so arranging the subject within the space that there is a single interest. Centre the attention upon the point of interest. Avoid confusion of interests. There should be variety and contrast, but the whole should give one simple, clear impression. The lighting involves an appreciation of beauty of dark and light massing. I should recommend a study of the charcoal drawings of William M. Hunt, the works of great etchers, Rembrandt, and Japanese prints. Here again, though there may be many tones, whether strong in contrast, or very delicate, they must unite in one impression.

**Mounting.**—This is a question of proportion, or line, and to some extent of colour. I think that some kind of a narrow border next the picture is usually desirable, but there can be no general rule.

**ON LEASING PHOTOGRAPHIC PREMISES.**

In an article in our issue of May 24 we discussed some of the points that should be taken into consideration when about to purchase a photographic business. It seems useful now to refer to some others that should receive attention when premises are about to be rented for photographic purposes, whether there is a studio already in existence there or not. If a studio is already built it may be fairly assumed that it conforms to the building laws of the district or it would not be standing.

As regards the premises they are frequently let on a yearly tenancy, or on a lease for a term of years—usually seven, fourteen, or twenty-one. Others are let on a three years' agreement, with the tenant's option at the expiration of that time of a lease at a certain rental, generally the same as that in the agreement. In such an agreement it is usually stated that the tenant must give a clear six months' notice prior to its expiry of his intention to take up the lease. Unless that is done the landlord is not bound to grant the lease at all. A yearly tenancy may be terminated by either party by giving the other six months' clear notice, in writing, to expire at the same quarter as the tenant entered into possession. If that, for instance, was the March quarter, the notice must be given before the previous Michaelmas Day. If it were served later than that by the landlord the tenant could hold possession until the following March twelvemonth if he so wished. On the other hand, if the tenant gave notice later than the Michaelmas Day, the landlord could hold him for a similar time—from the following March twelvemonth—and he could be compelled to pay the rent whether he occupied the premises or not.

When premises are rented on a yearly tenancy it is for the landlord to do necessary repairs, but he is not compelled to do them unless there is an agreement to that effect. With leases the tenant is bound to keep premises in thorough repair, and also to leave them in repair at the expiration of the term again, unless there is an express agreement to the contrary, which there rarely is. In leases there is usually a covenant that the outside woodwork is to be painted with two coats of good oil colour every three years, and the inside painted and papered every seven years. Also that the rent is not paid within a certain number of days after it becomes due the lease becomes void, and the landlord takes possession; this is, however, seldom put into effect except when the landlord wishes to get rid of his tenant. A clause is inserted in most leases to the effect that the tenant must not sub-let the whole or any portion of the premises without the sanction of the landlord.

Not infrequently there is a stipulation that the tenant fully insures the premises against fire during his tenancy, but usually the landlord does this at his own expense. In the case of fire the tenant has to pay the rent during the time that the premises are being repaired, or even more, although they may be of no use to him the while. He can, if he chooses, insure the rent as well as the contents of the place, and it is a good plan to always do this, as a fire may cause such damage as may take months to repair.

In taking a lease of premises that have not been used for photography before, the lessee should take the precaution to see that the lessor has the power to grant one. It often happens that the terms upon which the lessor holds the property may prohibit certain businesses being carried on—photography possibly among them, in which case the lessee might be prevented by the real owner of the premises from using them for the purpose for which he requires them. In such an event the lessee has cause of action for damages against the lessor. But trouble in this direction is best avoided by the lessee ascertaining for himself whether the lessor has the power to lease the premises for the business for which they are required.

In taking photographic premises which are only a portion of the building—say, for example, the upper part of the house and part use of the entrance hall—the tenant should have it definitely stated in the agreement that the portions of the entrance are to be his property for the purpose. The landlord may say that the whole may be let for the purpose, but such verbal agreement is not binding, and he may change his mind at some future time. The actual space to be used for showcases should always be mentioned in the agreement or lease, and then it becomes binding. We have known disputes to arise over the matter when the agreement was only a verbal one. In the agreement there should also be a stipulation that the tenant, and his customers, have free entrance to the premises at all times. For instance, the landlord should choose to close his portion of the premises at a certain early hour, and that might include the doorway, in which case the tenant's customers might be shut out.

When a photographer proposes to take premises in a private house—with the object of building a studio there where upon them, say in the garden, he will naturally go to that outlay unless he be granted a lease for a long term—such as one for seven years, renewable, or an option, for fourteen or twenty-one years. These terms should be insisted upon, otherwise after a tenant has to considerable expense, and built up a good business, he may have to turn out at the end of the seven years, and pay a much higher rent if he takes up a fresh lease. In taking a place in these circumstances, a number of points should be investigated before the lease is signed. In

place, the would-be lessee should fully acquaint himself with the building law, and with the by-laws of the act, or he may find, when too late, that they prevent erection of the studio in the form he desires, notwithstanding the fact that the lessor has given permission for the should also notice the surrounding buildings, and building will interfere with any "ancient lights." Does he may be restrained by neighbours from putting at all, or find himself involved in costly litigation images. Although the lessor may let the place with right to build a studio upon it, the ground landlord have a voice in the matter. In residential neighbourhood, where land is let on building leases, there is frequently a stipulation in the original lease that no business be carried on in any buildings erected upon it. A of this kind came under our notice some years back. Photographer took a large house, and, at great cost, a studio in its spacious grounds at the back, and d a high-class business. He was soon afterwards with an injunction, and had to close the place forth- We mention this to illustrate the care that lessees

should exercise before taking premises with the idea of building a studio on any part of them. Although they may have the full permission in all good faith of the lessor to do so, yet it is possible that it does not amount to a legal permission.

If a photographer builds a studio, we will say in the garden, he cannot remove it at the expiration of his tenancy, as it becomes the landlord's property, and moreover, by the terms of his lease, if a repairing one, he will have to leave it in good repair. This, of course, assumes that there is not a clause in the lease that at its expiry the building may be removed by the tenant.

These alone are some of the points that should have careful attention before any lease is signed. Too often such agreements are signed before the lessees have made themselves fully acquainted with their conditions and the responsibilities they are entering into. Leases should always be studied, and all their conditions thoughtfully weighed before they are sanctioned. If this were done, often misunderstandings and occasional litigation might be avoided.

## THE EXHIBITION OF REFLEX CAMERAS.

ims at giving general prominence to the advantages of ex type of camera appear to be on the eve of realisation. nouncement of an exhibition of instruments of this kind, examples of their use, has led to our receiving a larger r of photographs than we can display, and to the receipt e a budget of correspondence asking for advices as to e and place of the exhibition. In consequence of one tal reference to the exhibition as already open, some l-twenty persons visited the "B.J." offices, and were ointed to learn that they would have to wait until for the opportunity to examine the collection of cameras. er, in less than one week now—on Thursday next—these ot photographers may satisfy their curiosity as to the dern and efficient type of camera, and the various excel- ms in which it is obtainable commercially.

but one or two exceptions the exhibition completely nts the makes of camera obtainable. In one or two es the instrument shown will make its first public appear- The features of these new pieces of apparatus and of the atterns will be described in next week's "B.J.," with the e we intend, that the issue shall form a convenient source ence to the present available reflex apparatus. The full xhibitors is as follows:—

ex" (Adams and Co.).  
xrelist's" (J. H. Dallmeyer, Ltd.).  
ex" (City Sale and Exchange).  
orn" (Houghtons, Ltd.).  
lex" and "Premo" (Kodak, Ltd.).  
lenge" (J. Lizars).  
" (Marion and Co., Ltd.).  
nd G." (Newman and Guardia, Ltd.).  
n-Lens" (Ross, Ltd.).  
al" and "Mitre" (A. E. Staley and Co.).  
to" (Spiers and Pond, Ltd.).  
land" (Sanders and Crowhurst).  
al" (Talbot and Eamer).  
or, Taylor, and Hobson" (Taylor, Taylor, and Hobson, Ltd.).  
ar" (Voigtländer and Sohn).  
us" (W. Watson and Sons).  
smann" (Charles Zimmermann and Co.).

ecting the photographs, of which some 120 will be shown, advantage has been given to those exemplifying some parti- vantage of the reflex camera, even when in some technical it may be deficient. We shall say more on this matter

next week; but in the meantime we would commend a study of the prints as showing the adaptability of the reflex camera to subjects of the most varied character. The conclusion from them must be, we think, that, with the exception of wide-angle photographs, there is no type of work for which a reflex cannot be successfully used, and that the percentage of negatives in which the intention of the photographer is realised is higher than in the case of any other description of camera.

The list of the exhibitors includes photographers engaging in very different branches of the art, and as a result the collection should be about equally of interest to the technical photographer, the pressman, and the pictorial worker—to adopt a classification by aim rather than by method, which latter is, after all, much the same in all three cases.

Herbert Bairstow.	Charles Kirk.
F. T. Beeson.	F. B. Kirkman.
G. W. Beldam.	Percy Lewis.
Rev. Harold Burton.	W. Marshall.
Gordon Chase.	W. J. Melhuish.
F. Martin Duncan.	P. R. Momber.
J. F. Duthie.	Oliver G. Pike.
Dr. Fletcher.	J. H. Saunders.
Riley Fortune.	J. A. Stewart.
A. R. and Miss Hunt.	W. Thomas.
S G. Kimber.	W. L. F. Wastell.

In addition to the notes on the apparatus and pictures we would draw attention to several articles on reflex work which will appear in the "B.J." during the next week or two. These include:—

"The Reflex Camera in Professional Portraiture." By Gordon Chase.

"Natural History Photography with a Reflex." By F. Martin Duncan.

"Why I Use a Reflex" By W. Thomas (explaining the gains which a pictorialist derives from the reflex type of camera).

"The Reflex as a Universal Camera." By Arthur Marshall.

These contributions by notable users of reflex cameras will, it is hoped, prove particularly instructive to those who take the opportunity of seeing the instruments for themselves. As already announced, the exhibition opens on Thursday next at 10.30, and remains open until July 6, each day from 10.30 to 4.30 (Saturdays, 10.30 to 12.30).

# ACCURACY AND EFFICIENCY OF MODERN SHUTTERS.

## II.

IN the last article the question of the duration and efficiency of shutter exposures was considered, and it was seen that the duration of an exposure was the time that elapsed from the moment the shutter began to open, and expose the plate, until the moment the shutter finished closing; and it was seen that the efficiency of an exposure depended on the amount of active light that was cut off by the shutter during its operation of opening and closing.

There are, however, in reality, two kinds of exposure duration given by all shutters except those which work between the lens. It will be seen from Fig. 1 that a roller-blind shutter allows the

Fig. 1.

Fig. 2.

rays of light from the foreground to reach the lens before the rays of light from the sky are admitted; and similarly cuts off the light from the foreground before it cuts off the rays of light from the sky. This might be called the total duration of the exposure, and is of no practical importance with any shutters except focal plane shutters, when it demands our consideration. The exposure duration that we have to deal with is the local duration of the exposure; that is to say, the actual duration of the exposure that is given to any one portion of the plate; and fortunately it is this kind of duration that is measured in testing shutter speeds.

### Testing Shutter Speeds.

Imagine a pendulum swinging with even beats of one second each. At the lower end of this pendulum there is a tiny mirror which is brilliantly illuminated, and behind this mirror is placed a graduated scale, marking the distance the mirror will travel in hundredths or thousandths of a second. The shutter is set at one of its nominal speeds, and the swinging pendulum photographed. The resulting print depicts the graduated scale, and a tiny streak of white shows exactly how far the mirror has travelled during the exposure, thus recording the duration of the exposure.

Now, if shutters opened in a moment, remained open during the exposure, and closed in a moment, this method of speed testing would suffice; but, unfortunately, most shutters take so long opening and shutting, and cut off so much of the light during these operations, that it is necessary to determine the amount of light that actually strikes the sensitive plate.

With roller-blind shutters it is easy to calculate the efficiency of all the "instantaneous" speeds, when once the duration of the various exposures has been ascertained; and as Messrs. Beck, of 68, Cornhill, will test the duration of a shutter's speeds for the nominal sum of fourpence, there is no excuse for a photographer to remain in ignorance of the actual speed at which his shutter works.

The ratio of efficiency with various widths of blind openings was given in the last article; and if it is, for example, found that the lens aperture is 1 inch and the blind opening 2 in. wide, the foregoing table points out that the speed durations multiplied by  $\frac{2}{3}$  give the efficiency. Thus Messrs. Beck may mark the speed durations as 1-14, 1-22, 1-38, 1-56, 1-84 sec., and the efficiency will work out at 1-21, 1-33, 1-57, 1-84, and 1-126 sec. re-

spectively; and so if the full and correct exposure for a certain subject on a certain plate be 1-57 sec., an exposure of 1-38 will be given with an efficiency equal to 1-57 sec.

The efficient speeds of a sector or iris shutter must be found by a somewhat more difficult and complicated method. Given the duration of an exposure, it must be ascertained how long the shutter is fully open, and how long the shutter is opening and shutting; the former period gives full efficiency, and the latter gives on an average  $\frac{1}{2}$  efficiency with the sector and iris shutters and about  $\frac{1}{3}$  with the "Unicum" and "Automat."

First the speed durations must be found in the customary way; then the centre of the lens must be covered, and the speed durations again taken, which gives the time that the shutter is fully open at the various speeds; the period that the shutter is opening and closing is found by the simple expedient of subtracting the time at full opening from the duration of exposure.

The most accurate way of covering the centre of the lens, in order to test the period that the shutter is fully open, would be to place a circular piece of thin glass in the lens tube, close the diaphragm, and attach a circular piece of black paper cut to shade smaller than the largest aperture of the diaphragm.

Supposing the total duration of the exposure were 1-30 sec. and the shutter was found to remain fully open for 1-60 sec. then the opening and closing would also occupy 1-60 sec. find the efficient exposure with an iris shutter: Add the time at full opening to one quarter of the time spent in opening and shutting: 1-60 sec. +  $(1-60 \times \frac{1}{4}) = 1-48$  sec. Thus the efficiency of this shutter at an exposure of 1-30 sec. duration would be 1-48 sec.

At the higher speed of 1-50 sec. it would probably be found that the opening and shutting occupied 1-60 sec., and the total efficiency of the shutter would work out, 1-300 sec. fully open plus 1-60 sec. at quarter efficiency =  $1-300 + (1-60 \times \frac{1}{4}) = 3-48$ . That is to say, an exposure of 1-50 sec. duration might work out at about 1-133 sec. efficiency; which shows how important it is to ascertain the efficiency of this class of shutters.

Having found the efficiency of a sector shutter with the lens at open aperture, one would have to make a new calculation in order to find the efficiency with a stopped-down lens. For example, if the lens were uncovered in 1-100 sec. at  $f/8$ ,  $f/11$  would probably be uncovered in 1-200 sec. Life is too short for such calculations, and I think one should rest content with the efficiency of the lens at full aperture. One usually works with an open aperture at high speeds; and, well, a trifle of overexposure with a lens at  $f/11$  is rather an advantage than otherwise.

I consider that all diaphragm shutters should be marked with both the duration and efficiency at the various speeds; the former to ascertain the necessary exposures for moving objects, and the latter to show the correct exposure for a fully exposed plate. These figures should be ascertained by actual test, and not estimated or guessed.

### The Focal-Plane Shutter.

For the past four years I have used nothing but focal-plane shutters for hand camera work, so I write with some practical experience. With ordinary care in loosing the tension spring after work, and keeping the shutter free from dust and dirt, the focal plane shutter is the most accurate and reliable of all shutters; and the efficiency at all speeds is practically equal to the local duration of the exposure.

In the past this shutter has suffered much from being misused

misunderstood; and even now many seem to have an impression that an exposure of 1-100 sec. with a focal plane shutter is an efficiency equal to 1-35 sec. It is, of course, true that an exposure of 1-100 sec. with a focal plane shutter is probably equal to an exposure of 1-35 sec. duration with a cheap lens shutter; but this is because the latter is inefficient and not because the focal plane is super-efficient. Leaving races and similar press work out of the question, hand-camera exposures usually run from 1-10 to 1-100 sec., and the focal plane shutter is the ideal method of giving correct and efficient exposures of this class, and producing hand-camera negatives technically equal to any produced by the stand-camera. With the focal plane shutter the efficiency and local duration of the exposure are practically equal, but the local duration and total duration may be widely different. As the shutter slit wears down the plate it gives an efficient exposure to each part of the plate in turn; but if the slit be very narrow the total duration of the exposure may be much greater than the local exposure given to any one portion of the plate. Say an exposure is given at the lowest tension of a  $\frac{1}{2}$ -plate shutter which gives the slit across the plate in 1-11 second; if the slit be widened to 1-16 in., this slit will pass any one point in 1-600 sec., giving an exposure of 1-600 sec., and yet the total duration of exposure will remain 1-11 sec. Now, supposing a running race were photographed with this arrangement of slit and tension, so that his image was 2 in. high in the photograph, the head would take 1-19 sec. to travel 2 inches from his feet to head, during this time the head would have moved nearly  $\frac{1}{2}$  inch upward on the plate, and although each part of the figure would be sharp, he would be depicted as in A, Fig. 2. If, on the other hand, the tension had been fully tightened, and the slit widened to 1-16, the head would only have travelled 1-6 of an inch during exposure, and the distortion would give an idea of speed to the figure rather than bad drawing.

From this it is evident that when rapidly moving objects are photographed with a focal plane shutter, the slit should be as wide as the exposure will permit, and the spring at full tension; in fact, in most work the best way is to have the slit as wide as the speed will allow.

In photographing quickly-moving objects the shutter should, if possible, work so that the slit travels the opposite way to that in which the object moves on the focussing screen, thus reducing distortion to a minimum; but, save in very exceptional circumstances, the distortion given by a focal plane shutter is theoretical, and not of any practical importance.

#### A Suggested Focal-Plane Shutter.

Shutter makers seem impressed with the idea that photographers desire to photograph nothing except diving men, and racing horses, and express trains with their focal plane shutters; at least, their latest departure is the construction of shutters working at from 1-200 to 1-2,000 sec. This departure is much to be regretted.

Speaking in behalf of a large class of pictorial photographers: "We want our hand-cameras fitted with focal plane shutters, not in order that we may photograph what we consider freak subjects, but in order that we may give accurate and efficient exposures ranging from 1-15 to 1-100 sec. Given a rapid lens, a bright subject, and a strong light, we prefer to give 1-40 sec. with a colour screen and ortho plate, rather than race the shutter across the plate at the rate of 1-200 sec. What could be simpler than to construct a focal plane shutter on exactly the same lines as the Thornton-Pickard 'Royal' shutter, with a slit the width of the plate, and a tension spring to give speeds from 1-15 to 1-90, and a device to give time exposures?" I hope Messrs. Thornton-Pickard will see their way to the introduction of such a shutter.

A. J. ANDERSON.

## COMMENTS ON MR. R. J. WALLACE'S STUDIES IN SENSITOMETRY.

An important paper by Mr. R. J. Wallace in the *March Astrophysical Journal*, republished in the "B.J.," May, 1907, affords a welcome indication that it is becoming recognised that accurate quantitative knowledge of photographic plates is essential to their use for scientific subjects. There is no need to emphasise the increasing reliance placed on the photo-film for detection and measurement of the most diverse phenomena. One can recall sadly uncritical work by men of whom better is to be expected. In one instance a scientist of world-wide reputation published results on the chemical action of radium, in which the opacity, in H. and D.'s nomenclature, was taken as a measure of chemical action. In another, where a photographic measure was used to determine the absorption of X-rays solutions, the authors stated that, "as has been shown by Porter and Driffield, the density depends somewhat on the development." The italics are my own. It is very desirable that the number of those working on the quantitative problems of photography should be increased, and one welcomes Mr. Wallace's work both for its object and its substance, and he, I, I know, recognise and encounter such criticisms as follow put forward in no carping spirit.

To deal with all the points fully is impossible. The proposal to establish the grating replica as a standard dispersion piece seems a valuable step toward standardisation, particularly if the same uniformity can in the future be secured in their reproduction, and the generous way in which Mr. Wallace is putting them in the hands of fellow-workers deserves every recognition. The spectrograph described ("B.J.," May 24, p. 388) seems admirably suited for the purpose. One point only seems worth mentioning, viz., the use of milk-glass before the slit. Most forms of milk-glass alter the spectral distribution of the light incident, and if free from pronounced selective absorption. The writer

has found that a very good diffusing medium can be prepared for photometric purposes by the use of starch, by a modification of a method suggested by Foucault (cf Crova, *Ann de Chim.* [ii] 6 342).

Finest starch-powder is further refined by rubbing with distilled water and straining through fine gauze. After settling it is mixed with dilute water-glass solution, thoroughly stirred, and allowed to dry on carefully levelled glass plates. The quantities taken vary, of course, with the opacity required. Such films possess excellent diffusing power for a comparatively low opacity, and examined spectrophotometrically show no selective absorption from  $\lambda$  4300-7000.

Mr. Wallace prefers the Brace spectrophotometer, and describes a form well adapted for spectro-sensitometrical work. Whilst not denying the probably greater sensitiveness obtainable by the Lummer-Brodhura contrast method, I think Mr. Wallace underestimates that given by the Hüfner, as the very fine dividing line may be caused to vanish by just throwing the telescope out of focus. The Hüfner instrument also has the advantage that fog-readings may be automatically subtracted, which would not be so easy with the Brace. In the use of the polarisation method for reducing intensity there is, as Mr. F. Twyman (<sup>1</sup>) has recently shown, a considerable source of error, to which all polarisation spectrophotometers are liable, viz., the polarisation of the light of transmission through the dispersion prism, whether it be of the ordinary 60 deg. type or another. This is greatly reduced, and can be entirely avoided in the Hüfner instrument by proper choice of the glass and angles of the Hüfner-Albrecht rhomb, but probably infects Mr. Wallace's instrument to the full extent. Its chief effect is on the lower

<sup>1</sup> "Phil. Mag.," 1907.

densities, leading to too low values, for example, in the under-exposed portion of the H. and D. curve.

Mr. Wallace has made measurements of the spectral and total variation of the intensity of daylight, and considers that in spite of these it should be generally adopted as the normal light in sensitometry. With regard to the first, blue sky and white cloud are not a very great range of conditions, and even here Mr. Wallace's measurements exhibit a difference of 50 per cent. in the yellow maximum compared with the blue, nor would it be quite fair to reduce this difference relatively by longer exposure, as this would naturally affect the blue less as being nearer the region of over-exposure. Precht and Stenger<sup>(2)</sup> have investigated the variation in the spectral intensity of daylight by determining photometrically the ratios of exposures behind three screens—blue, green, and orange, under diverse atmospheric conditions. The ratios varied from 1:3:9 to 1:5:20, there being generally a decline in the green and red action as the total intensity is less. Certainly if Mr. Wallace's method be adopted great care must be taken to adhere to definite weather conditions.

With respect to the modified system of H. and D. sensitometry proposed, one does not quite understand, since Mr. Wallace allows the validity of the law of constant density ratios, why he does not accept the sensitometric import of the *inertia* or point where the straight line in the H. and D. curve cuts the base. If this be taken, it is not absolutely necessary to compare plates, as Mr. Wallace would, at a period of equal development action, which involves the extra labour of determining the development-time curves, and calculating from these the times necessary for

equal amounts of development. Whilst dealing with these points it may be mentioned that the alteration of gradation obtained by exposure to differently coloured lights (Abney) appears, from investigations by Dr. Mees and the writer, as well as by other workers<sup>(3)</sup>, not to affect  $\gamma$ , the development factor, but rather the form of the curve. Again, whilst chemical differences in the parts may affect  $\gamma$ , they are not likely to affect the velocity of development, as Mr. Wallace seems to think ("B.J.," May 31, p. 410), and these two factors in the development-curve must be kept distinct. The use of a secondary check-plate with daylight would really involve simultaneous checking of the secondary plate on an artificial normal, and even more work than Mr. Wallace proposes.

Returning to spectro-sensitometry, it is possible that Mr. Wallace under-estimates the value of definite speed tests behind broad-banded filters, combined with reference to the spectrum. For the spectrum curve (density against wave-length) hardly gives quite reliable sensitiveness numbers, even when, as Mr. Wallace suggests, Abney's method of interpolating the measured density into the density-exposure curve and so obtaining an equivalent light-intensity is used. This is owing to the aforementioned variation of the density-exposure curve with the wave-length. None the less, Mr. Wallace's precautions, viz., constant maximum of action at, say, 2.5 density, constant development conditions, etc., are calculated to give the most reliable results from this method. One will await with interest the further instalments promised of this series, in which probably some of the points touched here will be more fully dealt with.

S. E. SHEPPARD, D.Sc. (Lond.).

<sup>3</sup> "Theory of Photography Process," p. 297.

## MODERN PHOTOGRAPHIC PLATES AND FILMS.

A good camera is of assistance in photographic work, but a reliable plate or film is an absolute essential, for while it is possible to muddle along with weak, rickety apparatus, there is no salvation possible when faulty plates are employed, and, although this question of plate is, for ordinary work, not so serious a matter to decide nowadays as in years gone by, yet it is well to have some notion of those peculiarities each make exhibits, and then be able to adopt the one which seems best to lend itself to particular needs.

There are no bad photographic plates—at least I know of none—on the English market, but even so, there are differences observable in results given by one make, as compared with those of other brands, and it is our business to find those best suited for our own work. This is not a difficult or lengthy process; it simply means spending an hour or so, making a few test exposures, then comparing results produced.

### An Easy Means of Plate Testing.

For the purpose of these tests, perhaps the most convenient means is the Chapman-Jones plate-tester, a small quarter-plate screen, which, when exposed in front of a sensitive film or plate for a specified time to some standard form of light, will, on the plate being developed, tell at one glance both the general sensitiveness of the emulsion with which it—the plate—is coated, and also the extent to which it is sensitive to yellow, green, and reds; thus, by making one exposure and developing it, we may test any plate and see just the extent to which it is likely to fulfil requirements. The only precaution necessary is to deal with each test in exactly the same manner; that is, always to expose the plate at same distance from the same volume and quality of light for exactly the same period of time, then to develop in same kind of developer, used at one standard strength and temperature, and to continue the plate

or film to its action for one fixed length of time. Then we may see just the differences each plate shows, and note whether they seem better or inferior to those already dealt with.

This testing of plates may seem a dreadfully technical task, but believe me it is no such thing. It may be done in a odd spare moments, and in return gives truly valuable information with regard to what may, and may not, be expected from any sensitive-coated film or glass plate, while it certainly renders anyone independent of puff advertisements which may suggest greater advantages than practical experience justifies.

### Speed of Plates.

What a bone of contention this question of slow versus rapid plates has always been; yet it is simple enough, depending entirely upon the object for which the plates are used. For instance, in making a series of copies from prints, engraving etchings, and such like, there would be no substantial advantage in doing the work with ultra-rapid plates. Indeed, the reverse, for apart entirely from difference in cost of materials there is less difficulty in obtaining negatives giving strong black and white prints when slow plates are employed. On the other hand, there is no particular advantage in choosing very slow plates, when, say, ordinary landscape subjects are being done with stand cameras and timed exposures of several seconds' duration. For this purpose a moderately rapid plate answers perfectly, reducing the time of actual exposure to reasonable limits, and so avoiding many risks which accompany unduly protracted exposures on outside subjects. But when it comes to work with quick shutter exposures, then real fast plates are not only necessary, but possess every advantage, and nowadays they have been brought to such perfection that the results produced by them are in every way as technical

as are obtained on any form of slow plate, given a called time exposure.

The whole question simply resolves itself into selecting kind plates in regard to the class of work to be done with them.

#### Colour-sensitive Plates.

Here we tread upon more difficult ground, for matters are reduced to properly understand which demands at least a knowledge of colour and its equivalent value in monochrome. Failing this, it is only possible to go groping along, producing results more or less satisfactory, without being able to avoid faults or to attempt in any way to remedy them.

Photography of to-day is in quite a different position from of a few years ago, for as a result of the demands (made by those more artistically inclined) for plates which should be capable of recording other colours than the blue and violet of the spectrum, most, if not all, of the makers of plates and films produce some sensitised to green, yellow, and to the red rays. This is an enormous advance, for it means when a strong colour to be translated it may, when those plates are employed, be done with some degree of accuracy, for the results produced will give a more true representation than is possible when the ordinary plate only is available. The latter has been useful in the past, and is necessary when extreme speed is the chief matter of importance. It fails, however, in artistic work, for the all-important reason of its undue sensitiveness to light rays which are invisible to human eyes, while it exhibits a corresponding sensitiveness to those colours which form so important a feature of nature, as viewed by humanity at large. With regard to colour-sensitive plates there is a deal of unnecessary variety. They are, after all, nothing more than just good ordinary plates, to which in process of manufacture one or more dyes have been incorporated, so as to increase their sensitiveness to special colours; the doing of this in no way detracts their usefulness for ordinary purposes, and to deal with them is about as useful as it would be to resent an offer by host to guest of a little choice wine with dinner, a good cigar and coffee afterwards.

Another matter needs keeping in mind, especially when plates are chiefly employed for rapid shutter exposures, when the least sensitiveness of emulsion is necessary. Under these circumstances it is impossible to expect any ultra-rapid plate in present conditions of manufacture to be at all correctly sensitised for colour, and there is a present limit to speed in relation to greens, yellows, and reds. Therefore, where the blue

and violet sensitiveness is pushed beyond a certain point, and that speed quality is utilised to its full extent, then there is little if any visible alteration in the resulting negative or print from what would be the case had an ordinary plate of extreme speed been used. It is for this reason yellow or olive screens have to be used, in order to destroy the excess of sensitiveness to blue and violet. While this remains the state of affairs, it really means there is no advantage in pushing the speed of colour-sensitive plates beyond a point when sensitiveness to the less active colour rays may exert their full influence during such exposures as may be given.

Some day it may be different. Then the ideal plate may come, screens be relegated to museums, colours be automatically recorded in true relation one to another. But for the present, when it is desired to deal with subjects demanding rapid shutter exposures, we can only obtain full exposure and at the same time some reasonable measure of correct colour-rendering, by employing, in addition to the best plates, lenses of wide aperture; that is, by passing a strong flood of light to make up for any reduction of general plate speed.

#### Colour Screens.

The use of screens of coloured glass or stained gelatine slows down the effective exposure just in proportion as it either allows the whole colour rays to pass unobstructed, or cuts them off to any lesser or greater degree. What is needed, and what experimentalists are striving to arrive at, is a dye which will effectively cut out any excess at the blue and violet end, while allowing the yellow and reds to pass unobstructed and unaffected. When this is done, the effective speed of a plate will be retained at a much higher ratio.

The old saying of the strength of a chain being just that of its weakest link may be applied to this question of the orthochromatic speed of a plate. It is simply governed by that of its slow end of the colour range, for which it has been especially sensitised, if, when used, it is intended to utilise to the fullest extent the influence of those same colours.

I am afraid this is a very unscientific description, but it may help to make clear the principle which governs this question of colour-sensitive plates, sufficiently, at least, to enable unscientific folk like myself to use them, and reap the undoubted benefits they bestow.

Photographers aiming to be artists in their own medium must understand something more than is contained in a six-penny guide-book, for it is as true to-day as in the past, the greatest artist in his own medium is also the truest technician.

W. THOMAS.

## THE DAYLIGHT SENSITOMETRY OF PHOTOGRAPHIC PLATES AND A SUGGESTED STANDARD DISPERSION-PIECE.

### IV.

#### Relative Speed.

The method now advanced by the writer consists in selecting some plate whose quality and general behaviour present a reliable unity against which all other plates may be compared. In the "27" Gilt Edge we have a plate which may fairly be considered to meet the requirements, because, in spite of the fact that occasionally it has suffered a slight drop in speed, it is characterised by a remarkable uniformity.

Firstly, the speed of a plate is required to be known. It is cut in a manner that it, together with a "27," may lie in the holder and be exposed at the same time behind the revolving sector-disc to some light-intensity. After exposure, each plate is cut into two halves, and all are developed at the one time and at constant temperature, being removed from the developer in pairs after the lapse of 8 and 12 minutes respectively, and then fixed, washed, dried, and stored.

From these measurements is extracted  $\gamma$ , and the time necessary to reach, say,  $\gamma = 1.0$ , is read off directly, and used as a time factor for the development of another pair of exposures upon two more of the same plates developed at a similar temperature.

The measurement of this second pair of plates will in turn give curves which lie parallel to one another, and from which the relative speed may be obtained.

One measures, therefore, the distance apart of the curves (horizontally), and, remembering that the exposure increase for each step rises in powers of two, the difference in speed between the two plates for a given intensity of light of similar spectral composition will be two, raised to a power the value of which will be determined by the distance measured; e.g., the mean distances apart of the two curves in Fig. 9 is 3.2, then  $2^{3.2}$  is the difference in speed; or, the exposure time would have to be increased 9.19 times in order to obtain similar density.

In this method of relative speed determination there is the extra work entailed by the measurement of the "27" plate with every determination, but such work really amounts to very little in actual time, and has the added advantage in the use of daylight in place of some artificial "standard" of more or less doubtful value.

Experimentally, the writer has not been able to so accurately expose and develop a third pair of plates as to have the plotted results actually superpose, the difference from a mean curve being  $\pm 0.02$  of a density unit in the most favourable instances, and running up as high as  $\pm 0.05$  in exceptional instances. Further discussion upon this and kindred points is reserved for a following paper.

#### Colour-Sensitiveness ( $\chi$ ).

When Hurter and Driffield advanced their epoch-making methods for the sensitometry of photographic plates, the use of a candle in this connection was allowable, because at that time the orthochromatic plate was but little used and less generally understood. At the present writing there is scarcely a manufacturer of photographic plates throughout the world who does not prepare one or more brands of colour-corrected plates, and it is merely a question of a very brief time until the use of the orthochromatic plate will be imperative for everything save the photography of black and white.

When we consider the colour-sensitive plates of the present day as a whole, there are four points which strike even the casual observer as characteristic: (1) the strong sensitiveness to the blue-violet; (2) the secondary sensitiveness to the yellow-green; (3) the low sensitiveness to the blue-green; and (4) the lack of sensitiveness to the red. It is evident that these values should be definitely known, and that, whatever method is adopted for their estimation, it should be comprehensive enough to thoroughly differentiate them.

Mees and Sheppard have proposed the constant  $\chi$  as representing the ratio of the inertia of the blue-sensitiveness to the inertia of the yellow-sensitiveness. Their method of determining this value (which is an improvement upon the system of Eder) consists in exposing a plate to their screened acetylene light behind the sector-disc, which plate is still further screened by the interposition of a colour-filter transmitting only the red light to  $\lambda$  5900 (A-D).<sup>24</sup> Another plate is exposed in the same manner, but with the interposition of a green filter transmitting light from  $\lambda$  5900 to  $\lambda$  5000 (D- $\frac{1}{2}$ F), while a third plate is exposed through a blue filter transmitting light from  $\lambda$  5000 on ( $\frac{1}{2}$ F+). The densities of these plates are then measured, and the ratio of the inertias is obtained.

In the opinion of the writer, the division of the spectrum into three parts furnishes altogether insufficient information for either the scientist, plate-maker, trichromatic worker, or student of orthochromatism.

A plate exposed through the red colour-filter may give a very high value, and thus indicate a red-sensitiveness which does not exist, the action being due entirely to the orange at, say,  $\lambda$  6000, to determine which reference must be made to the spectrum. A somewhat different criticism applies to the results obtained by exposure through the green filter, whose transmission ends in the region of photographic low-sensitiveness in the blue-green. The elimination of this insensitive gap (or results tending to such elimination) is of considerable importance in practical plate-making, and therefore the relative values of plates for this region should be definitely recorded; the division of the spectrum at this point by the green and blue filters makes such determination impossible.

The method, however, has a certain broad value for the estimation of sensitiveness when required for use with wide-banded colour-filters, such as are generally used in trichromatic work; but it is unquestionably true that it cannot compare in quantitative estimation with a series of daylight spectrum negatives where the action of the plate for every wave-length of light is definitely apparent. As any system of sensitometry to be popular must be rendered as simple as is consistent with definiteness, then what could be easier than to quote the density-readings at, say, six points<sup>25</sup> of the spectrum measured, if any further numerical evaluation be required?

<sup>24</sup> The spectral transmission value of this colour-filter should be very carefully determined, as it is composed of rose bengal and tartrazine. This latter dye even in concentration transmits the ultra-violet at  $\lambda$  8700. The rose bengal of course transmits the violet very fully.

<sup>25</sup> The six points referred to may be at  $\lambda\lambda$  3800, 4100, 5100, 5500, 5900, 6100, for all of the ordinary orthochromatic plates. In cases of special red-sensitiveness then the density-value of a seventh point may be added.

#### Development of Spectra.

In the development of the spectrum plates obtained by exposure in the spectrograph as described, special care must be taken to make the following constants: (a) the constitution of the developer; (b) the temperature of the developer; (c) the time of development (as determined by the curve and corresponding sector-strip). Due attention to these points will result in negatives directly comparable with one another.

#### Measurement and Interpretation of Spectra.

In a series of spectrum exposures upon two different plates, one of each is selected for measurement whose region of maximum opacity corresponds approximately to a density of 2.5. This is readily selected by comparison with a standard density plate, on which the measured densities have been plainly marked.<sup>26</sup> No difference makes absolutely no difference whether this spectral maximum is in the yellow or in the violet. The only thing to look for is a maximum of 2.5.<sup>27</sup>

In the practice of the writer this is still more readily determined by setting the analyser circle of the spectro-photometer at 3 degrees, moving the spectrum plate in front of the collimator slit until it arrives at that one whose maximum opacity approximately equals the field in the viewing telescope; then that spectrum is marked for measurement. With a similar procedure on other plates we obtain spectra which may be compared directly with one another, because, generally speaking, they represent as their maximum an optical action of 256 light-ratio units, under identical conditions of development.

Using a narrow slit in the spectrophotometer, the spectrum selected may now be measured, and its curve plotted in the usual manner with the densities expressed as ordinates and the wave-lengths as abscissae; or, if preferred, the ordinates may read light-unit ratios, the values being obtained by interpolation upon the curves already obtained from the corresponding sector-disc negative previously exposed and developed at a similar temperature, and taking the true ratios as units. This method was advanced by the writer in a former paper,<sup>28</sup> and serves the very useful purpose of indicating at a glance the ratio of opacity to exposure for differing wave-lengths.

In such a spectrum record we obtain a quantitative estimate of the plate under test. Aside from the spectrum selected for measurement we see at a glance the true region of maximum sensitiveness evidenced in the shorter exposures. The growth of density in the least refrangible region with increase of exposure is readily marked, and its relation to the blue-sensitiveness may be easily approximated when the exposure time is known. If, for example, the spectrum selected for measurement as having normal exposure be the result of an exposure of  $a$  minutes, then the value  $x$  of the light-units acting at any point on some other exposure  $b$  may be expressed as  $\frac{b}{a}$ .

where  $c$  is the value of the light-units corresponding to the exposure selected for measurement. Furthermore, we do not have to depend upon the impression of a glass scale (for example), in order to record spectral position, in which there enters an element of uncertainty consequent upon accidental displacement of either that or the dispersion-piece, or looking at a print from such a record, the observer has absolute means of knowing whether the scale is in true position or not, to what extent the negative may be over-exposed. On the other hand, the daylight record leaves no element of uncertainty, because the Fraunhofer lines indicate at a glance the exact wave-lengths, and also serve to show over or under-exposure.

In all of the spectra exposed above normal there is present an amount of "fog" which arises from the "spreading" of the light in the region of maximum sensitiveness, and interior reflection in the spectrograph; furthermore, the overlapping ultra-violet of the second order spectrum is apt to lead to false conclusions in the estimation of colour-sensitiveness. For that reason the remaining two exposures are made after introducing the wedge between the collimator tube and the front board of the camera, the increase in the angle of incidence being small.

<sup>26</sup> Such a plate may be obtained from a Scheiner or a Hurter and Driffield sector-disc.

<sup>27</sup> Because 2.5 is conveniently the highest allowable density for reliable direct measurements.

<sup>28</sup> "Preliminary Note on Orthochromatic Plates," "Astronomical Journal," 153, 1905. It should be mentioned, however, that the values given in this form paper were from visual estimates, in place of the present measures, although the following paper (*ibid.*, 22, 350, 1905) confirms by experiment the values first derived.

thus causing a corresponding displacement of the spectrum on plate. An ammonium picrate colour-filter is then introduced in the slit to completely absorb the overlapping violet. These or two exposures are necessary to the correct appreciation of the extent of sensitiveness in the red. The appearance presented on a negative plate as has been described is shown in *f*, Fig. 1. It should be definitely understood that this suggested method of daylight sensitometry is advanced as a practical everyday means of arriving at reliably comparable results suited to the requirements, not only of the general worker in photography, but also of those who make use of the photographic plate in obtaining records of scientific value. No one is more conscious than the author that it has some points which may in time be improved upon, but it at least serves the useful purpose of definitely pointing out in condensed form the greater number of pitfalls and inaccuracies which beset the path of sensitometry, and further indicates a means of obtaining exceedingly good results with the minimum of time and expense. It will be obvious that the method is primarily suited to those who are users of plates, rather than to those whose work is principally towards the manufacture of the material. For this class, however, there is no reason why the method may not be extended to embrace the requirements suited to their needs.

#### Summary.

may summarise the foregoing and tabulate the entire process as follows:—

The advancement of the replica-grating as a standard dispersion-medium together with a simple form of spectrograph suited to its use. A suggested method of daylight sensitometry (making use, as far as possible, of the laws discovered by Hurter and Driffield), of the following is a résumé:—

Exposure of one  $2 \times 4\frac{1}{2}$  plate scored down the back, but not through, together with one  $2 \times 4\frac{1}{2}$  Seed "27" plate, for, say, 10 minutes, in the sector-disc machine.

The scored plate is broken through into two secondary slips, and four plates are now developed (preferably together) with a standard developer, for a constant length of time, and at a constant temperature, with the exception of one of the secondary slips which is in the developer for exactly double that of the others.

Measurement of the density strips and extraction of  $\gamma$ ,  $t_n$  and  $e$ .

Exposure of a second pair of  $2 \times 4\frac{1}{2}$  plates, and development for the time necessary to obtain equal amounts of development action as from *d*, retaining composition of developer and temperature as in *a*. Measurement of same and extraction of speed-ratio.

Exposure of one  $3\frac{1}{4} \times 4\frac{1}{2}$  plate to a series of eight exposures in a spectrograph, varying from two seconds to eight minutes, and further exposures on the same plate with the collimator wedge and through the ammonium picrate screen.

Measurement of selected spectrum for quantitative colour estimation.

ROBERT JAMES WALLACE.

#### INTERNATIONAL PHOTOGRAPHIC EXHIBITION AT DRESDEN, 1909.

Preparations for this undertaking go actively forward. On May 11 the committee was appointed and a committee for the carrying out of the exhibition was elected. It becomes more and more evident that the exhibition will prove to be an undertaking which will call for the energies of all branches of activity connected with photography.

Universal interest in the enterprise prevails, and from all parts of Germany, as well as from foreign countries, numerous volunteers send in their names, accompanied by unanimous expressions of encouragement of the scheme. And since the South German Photographic Union has announced its intention of abandoning its special exhibition of 1909 in Munich, in favour of one in Dresden, and has determined to take part in and help forward the undertaking, the experts throughout Germany with but few exceptions are agreed to produce something worthy of the occasion.

The composition of the programme and the practical construction of the exhibition make it desirable that any one-sided influence on the programme or on any one branch shall be avoided. Every group shall be brought into the work of authorities of that special branch. Every group shall be, from beginning to end, represented, and have its own special board (or committee) of experts.

With the judicial establishment of the directorate on May 11, at which the representative of Government was present, the work has made great strides towards the creation of its formal foundation. One thing, at all events, is apparent—viz., that the International Photographic Exhibition in Dresden, 1909, will take place, and on a comprehensive scale.

The offices of the exhibition are to be found at Dresden-A., Neumarkt 1, Hôtel Stadt, Berlin. All communications should be addressed there.

#### ORTHOCHROMATIC PLATES IN COMMON LAW.

[The following report reaches us without any indication of its sender. We can only say that we have been able to learn nothing of the existence of the Court referred to, although further inquiries at Bow Street have led to some hopes of light being thrown on the case in the suburbs. The Croydon police have the matter in hand.—Eds., "B.J."]

**SERIOUS CASE OF ASSAULT BY A PHOTOGRAPHER.**—Josiah Jeremiah, of no fixed abode, was charged at the Wellington Street Police Court with hitting E. J. Wilks on the head with a tripod leg. The prosecutor, who appeared with his head bandaged, alleged that in the course of a discussion as to the ingredients of the familiar penny sausage, the prisoner lost his temper, and committed the assault complained of.

The prisoner, in defence, admitted striking the prosecutor under circumstances of great provocation. Prior to his taking up photography he had been in the sausage trade, and knew for certain that the usual penny article contained, roughly, three parts of road sweepings to one of horseflesh. Prosecutor had quoted a "German authority," to the effect that the average ratio was 24 to 1. He (the prisoner) contended that anybody who quoted a "German authority" deserved rough handling. It wasn't playing the game.

He also pleaded that he had inadvertently acquired the pernicious habit of using "ordinary" plates in his photographic work. This had so blunted his moral senses that he was now incapable of distinguishing between right and wrong. In confirmation of this remarkable statement he drew the attention of the Bench to some editorial remarks and correspondence appearing in a photographic contemporary. The magistrates, after perusing the papers handed up, decided that justice in the case would be met by binding the prisoner over in his own recognizances. He would also be required to give an undertaking to use only orthochromatic plates and filters in future. The articles and correspondence they had read revealed a serious danger to photographers in general. It appeared to be a case for the Board of Trade, with whom they should communicate.

#### Patent News.

The following applications for Patents were made between May 21 and May 25:—

**SCREENS.**—No. 11,848. Use of opalescent screens in photography. Alfred Walter Dollond, 5, Montague Gardens, Wallington, Surrey.

**REFLEX CAMERA.**—No. 12,027. Improved folding reflex camera. Paul Ponge, 153, Croydon Road, Anerley, London.

**LENSES.**—No. 12,061. Improvements in lenses. George Lindsay Johnson, 322, High Holborn, London.

**PENDANT.**—No. 12,117. Improved photographic pendant. Clarence Flint, 44, St. Paul's Square, Birmingham.

#### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**MIXED DEVELOPER.**—No. 10,284. 1906. The invention consists of a developer containing both paramidolphenol and hydroquinone, combined in such a way that new chemical bodies are formed.

The manufacture of the new chemical body of paramidolphenol and hydroquinone which constitutes the subject of the invention may be effected as follows, by stirring together 100 grams each of the paramidolphenol and of hydroquinone with 200 grams of

glycerine or alcohol in a mortar into a paste, which is then poured into two litres of water, whereupon solution takes place immediately. If to this concentrated solution an equal volume of a sulphite solution, containing 25 per cent. of potash is added, a bulky, flaky white precipitate is deposited, while the supernatant liquid is first colourless and later on becomes bluish violet. The precipitate is thrown on a filter and washed several times with a 5 per cent. solution of potassium metabisulphite, in order to prevent oxidation of the precipitate, which is then dried in a current of dry sulphurous acid.

One gram of this compound will then yield a well available developer with 10 ccs. of the following solution: 50 grams crystallised sodium metabisulphite, 50 grams crystallised sodium sulphite, 50 grams dry carbonate of potash, and 5 grams potassium bromide, all dissolved in 1 litre of water.

It is remarkable, that when using the chemical compound, the temperature of the developing liquid is of minor importance in the development of the picture; the picture appearing, as shown by experiments within a certain standard period of time, independently of the temperature of the developing liquid, no matter whether this liquid shows 64, 55, or 46 deg. Fahr.

Reference is made by the Comptroller of Patents, in pursuance of the Patents Act, 1902, to the specification of Letters Patent, No. 27,931, 1896, granted to Julius Hauff. Karl Buisson, Emmendingen, Baden, Germany.

**GYROSCOPE CAMERA STAND.**—No. 10,757. 1906. This invention relates to aerial photographic apparatus and has particular reference to a device for holding a photographic camera in set position, more especially apparatus set into the air for the purpose of taking photographic views in a given direction.

It comprises a gyroscope, consisting of a vertical fly wheel connected to the instrument, the fly wheel being mounted so as to be rotatable about two horizontal axes at right angles to each other. After the instrument has been set, the fly wheel is caused to rotate at a very high speed, so that during the action of the fly wheel, which is suspended by means of a universal joint, the instrument can no longer turn about its vertical axis. The invention comprises means for applying a gyroscope to a photographic camera which is projected into the air. Alfred Maul, 29, Gohlisenstrasse, Dresden, Germany.

**FILM PACKS AND COLOUR PHOTOGRAPHY.**—No. 11,346. 1906. The invention relates to that type of film in which the films are carried or attached to a pleated band, each pleat having a separate manipulating tab.

In order to enable a number of such films to be developed at one operation in a developing machine the films are secured to a washable strip, so that the attachment shall not be affected by water, by means of a non-soluble cement or by making the film and strip of a single piece alternately sensitised and opaque.

Colour filters composed of suitably dyed transparent gelatine or collodion sheets may be attached to the pleated strip, or may form a part of it, the filters being arranged in sets suitable for trichromatic work, in order that exposures for the respective colours may be made in rapid sequence. Or the colour filters may constitute quite a separate additional strip, folded within the other one, each pleat having its own manipulating tab as before.

The colour screens, instead of being in sets of three for trichromatic work where three negatives are required to make a complete picture, may instead be those forms of screens which render all the desired colour effect on one film at one exposure, such as the ruled screen of Professor Joly, for example, or the films themselves may be prepared by any suitable means for giving the whole range of colour effect in one negative; as, for example, in the several well-known processes of Lumière Brothers, Professor Joly, and Dr. Smith.

The pleated strips or other attached films or backings may have an extra tab, termed a retaining tab, to each fold or film, at the opposite side to the pull tab, for securing same in position. The pleated strips may be made more flexible, for taking sharp bends quickly, by making a series of fine and close corrugations across its width, which also stiffen it in the other direction. John Edward Thornton, Altrincham, Cheshire.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Development by Time.

Mr. R. Child Bayley, writing on the method of finding the time to develop plates, says: Three quarter-plates are exposed on view from one of my windows, all for exactly the same time worked out strictly by the exposure meter. They are developed side by side in the developer selected, and the temperature of this developer is noted, as subsequently described. The time at which they are put in the developer is carefully noted the dish is kept covered. One plate is taken out as soon as judged by looking at it, back and front, that there is any likelihood of development being complete, the second when I should think undoubtedly properly developed as well as I can tell in the room, and the third has about as much longer than the second had than the first. Each is rinsed as soon as it is taken from the developer, the time is noted, and it is slipped into fixing bath. When fixed, it is easy to see which has been properly developed, and the time which that one had in the developer is taken as the standard time for that temperature. Should one of the plates appear to have had the correct time, it is easy to deduce from their appearance what the time should be. I heard it urged against this plan that it is absurd to think that the correct time of development can be ascertained in so simple a manner. If the essentials are observed, and particularly the following (below), it will be found that, "absurd" or not, it works. The essentials are:—

1. The selection of a suitable subject. A building with sun on it with some of it distinctly in shade, and with sky showing, is at the best and the most generally available.
2. Correct exposure. Information derived from incorrectly posed plates is sure to be misleading.
3. Proper care in measuring the temperature and the time of development.

### Tripod Substitutes.

A couple of chairs make a splendid stand (writes Mr. W. Knowles in the "Photographic Monthly"), if you place one up down on the other, and then a sheet of cardboard, a piece of board, a large book, or even a large picture from the wall, on top of the upturned legs. When out cycling, why not make a bicycle answer for a stand? Yes, but it is a bicycle, not a tripod, you say—the thing won't stand up. Indeed! Perhaps not the orthodox way; but stand it on its head, turn it upside down as though you were going to mend a puncture (thank goodness it is not!) and adjust the pedals so that one will hold your camera when propped up with a bit of stick. Surely you can get a bit of stick from the hedgeside to prop the pedal up. Yes, it is interesting to while away a half-hour in the village churchyard after a good lunch at the inn, but what a pity you have not your tripod, so that you might copy the curious epitaph on that gravestone. A snap-shot in the hand is no use. It will require at least a second, for you must stop down to get the letters sharp. Just set the shutter and press the camera up against that gravestone opposite, press it hard with one hand, and with the other touch the trigger. Ample exposure and no shake at all. In the same way press the camera against a door jamb, or a stoop, or a gate post, for an exposure.

**NORTHUMBERLAND AND DURHAM PHOTOGRAPHIC FEDERATION.**—Jas. Whittle, 39, Bridge Street, Morpeth, is now hon. secretary to whom all communications should be addressed.

**DR. C. E. KENNETH MEES.**—The current number of "Le Procédé" contains a portrait of C. E. Kenneth Mees and a brief biographical notice, from which we see that he was born in 1832, entered London University in 1858, and commenced his collaboration with Dr. S. E. Sheppard in 1901, with the result that the two young investigators have published a lengthy series of papers on sensometric and photo-chemical subjects, most of which have been read before the Royal Society, the Chemical Society, or the Royal Photographic Society, and have now been published in one volume Messrs. Longmans.

## New Books.

Investigations on the Theory of the Photographic Process." By E. Sheppard, D.Sc. (Lond.), and C. E. Kenneth Mees, D.Sc. (Lond.). London: Longmans, Green and Co. 6s. 6d.

Students of sensitometry and of the theories of the process connected with the development and fixation of a photographic plate will thank the authors of these papers for performing the equivalent of the tedious but necessary process of taking stock at the first term of operations. If we employ a commercial process it is with no desire of casting any aspersions of "shop" on the contents of the volume. Indeed, the most casual glance at the pages will show the absurdity of any such insinuation. In the few pages we may venture to utter any sort of criticism at all of a paper which in the present state of knowledge of the process is written by very few persons indeed are competent to criticise, it is the authors should not have given effect to a belief which we do not doubt they hold—namely, that their work is of great practical importance—and have been at some pains to subject it to a process of digestion, or semi-digestion, by which the general conclusions from their investigations should be brought within the comprehension of the many unable to extract it for themselves from the mass of facts and curves. The duty for the present must be left to the authors and willing to play the parts of Huxleys and Tyndalls to the Darwins. Or shall the task be postponed for a decade to some time for possible unverified conclusions to receive the needed attention? We dismiss the suggestion as uncharitable, and would leave the expositor to his task.

The authors preface the narration of their investigations with a discussion of the bearing of the modern physical conception of photography on development and with a description of the apparatus, used by themselves, with which they have carried out their work. Instruments, it is not too much to say, have already been widely adopted by others desirous of making similar measurements for research or commercial purposes. Thus in this portion of the authors' decisions in the matters of standard lights, exposing times, temperature regulators, photometers, and spectrophotometers will be preserved for reference with interest by those who are foreseeing the need of such instruments.

The use of this apparatus for the systematic examination of dry plates is the subject of the third part of the volume. The interpolation, constituting the major contents of the volume, concerns papers on microscopy of the image, theories of the latent image and of its development, of the action of restrainers and of developers which have been read before societies and have been known to the photographic general reader mainly from the occasional references to them. As we have already said, the authors may be congratulated on their appreciation of the needs of the student in selecting them.

Life at Home: How to Study and Photograph it." By R. Kearton, F.Z.S. London: Cassell and Co., Limited. 6s.

This is the fifth edition of the original issue of 1898. Mr. Richard Kearton once more tells of the fieldcraft which he has perfected in the course of stalking his furry and feathered friends sufficiently to enable him to take a camera. We see that the artificial tree trunk and the sheep have to be replaced by other properties in which Mr. Kearton can stand or lie for hours waiting for his subjects to pass. An artificial rock and a similarly fictitious sod house are other heroic measures for him, and he illustrates the various methods to which the naturalist-photographer is put in undertaking his work. And when the photographer of these subjects has mastered the vales and hills of the country-side there still remain the sensations of being lowered over the precipitous face of a cliff to pay a surprise visit to the shag or eyrie, on which kind of excursion Mr. Kearton is shown. The volume is not, as might be most largely occupied with these feats of nerve, but in its later chapters much timely advice on the methods of the photographer of natural life must follow. The book contains a large number of illustrations in the text and a photographic album.

CECIL SMYTH is now acting as the London representative of Messrs. W. and A. Wainwright, of Croydon.

## New Apparatus, &c.

The High-Speed Focal-Plane Folding Camera. Sold by A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C.

Messrs. Staley send for our inspection one of these cameras of the popular folding focal-plane type, which they advance chiefly for high-speed work. The illustration shows the form of the camera, which, from the practical point of view, is a very convenient instrument. The shutter has a rapid wind, and is set, from the outside, over a wide range of speeds. The camera, without lens, is sold complete with three double dark slides at £3 11s. 6d.

## New Materials.

Royal Standard P.O.P. Made by Cadett and Neall, Ashted, Surrey.

From samples of this new gelatine printing-out paper, sent to us by the special distributing agents, Messrs. Kodak, Ltd., we find it to be a P.O.P. of distinctive qualities, certain of which should possess especial interest for photographers in this country whose work has to be done under variable and trying climatic conditions. For the paper has a hardened emulsion and is remarkably immune to variations in the temperature of the washing water, retaining, without special measures, a firm surface, which facilitates certain and rapid work in the glazing of prints by squeegeeing to glass.

As regards ready and economical toning, it appears to us to be a satisfactory paper, whilst with the borax toning bath it yields a pleasing warm colour. The paper is supplied both matt and glossy, and, in both surfaces, as postcards.

## CATALOGUES AND TRADE NOTICES.

FERDINAND HRDLICZKA, 9 to 11, Lerchenfeld, Gürtel, Vienna, XVI/2, sends us a prospectus of a new flashlight installation for studio and at home portraiture. The apparatus is advanced for serious work, but is highly portable.

DIRECTORY OF DARK ROOMS.—The issue of our contemporary, "The Photographic Monthly," for the current month is a particularly bulky one, owing to the inclusion of a directory of dark rooms, running to several thousands of entries. British inland and seaside resorts occupy the larger proportion of space, but the principal Continental towns appear in their own portion of the directory, whilst there are some entries which conceivably may be of use to the traveller. The literary pages of our contemporary, we are glad to observe, show no signs of diminished interest; and the present number presents a variety of amateur topics, with the aid of half-tones, which are actually illustrative.

"VELOX" COMPETITION.—Messrs. John J. Griffin and Sons, Ltd., announce a monthly competition, in which prizes of two guineas, one guinea, and twelve consolation prizes of 5s. each are offered for the best print on "Vigorous" Art Velox paper. The prints must be mounted and must bear the name and address of the sender on the back. The competition is open only to those amateur photographers who have not gained an award in any previous competition. All prints must be addressed "Velox Competition," Griffin's, Kingsway, London, W.C., and must reach the firm by the last day of each month. Mr. F. J. Mortimer, editor of "The Photographic News," will act as judge.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, JUNE 7.

Tunbridge Wells Amateur Photographic Association. Open Night.

SATURDAY, JUNE 8.

North London Photographic Society. Outing to Hampton Court.  
North Middlesex Photographic Society. Outing to St. Albans.  
Mill Camera Club. Outing to Shoreham and Otford.  
Bowes Park and District Photographic Society. Outing to Benfleet and Canvey Island.  
Worthing Camera Club. Outing to Pulborough and Stopham.  
Hackney Photographic Society. Outing to Hendon and the Brent.

MONDAY, JUNE 10.

Bradford Photographic Society. "Fashions and Schools in Pictorial Photography." A. Bracewell.  
Southampton Camera Club. "The Making of the Negative." T. M. Weaver.

TUESDAY, JUNE 11.

Hackney Photographic Society. Novelties in Apparatus and Materials.  
Birmingham Photographic Society. "Mounting." Frederic Lewis. "Ozobrome." F. Cadby.

WEDNESDAY, JUNE 12.

Rugby Photographic Society. Outing to Braunston and Ashby St. Ledgers.  
North Middlesex Photographic Society. "The Oil Process of Printing." A. R. F. Evershed.

THURSDAY, JUNE 13.

London and Provincial Photographic Association. Queries and Answers.  
Handsworth Photographic Society. "Aristo-Edinol." C. P. Proctor.

### ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held Tuesday, June 4, the President, Mr. J. C. S. Mummery, in the chair.

The Secretary, Mr. J. McIntosh, gave a demonstration of the making of light-filters for orthochromatic photography, prefacing his actual demonstration with an explanation of the principles involved in the correction of orthochromatic plates by means of a light filter. Mr. McIntosh's method was to employ a fine transparent sheet gelatine, which he purchased from Huiskey's, in the Barbican, E.C. This was obtainable at a very cheap rate, and was remarkably free from flaws and streaks. A sheet of convenient size was immersed in the solution of dye or mixture of dyes, and the dish rocked until the gelatine became flaccid. The density of the dyeing was conveniently adjusted by a greater or less time of immersion. In the case of a pale green it was better to dilute the solution in order that the necessary intensity was not reached before the gelatine had been completely softened, as if this precaution was not taken the absorption of dye would probably be uneven. In other dyes the intensity was easily reduced by immersion in plain water. The dyed piece of gelatine was then laid on a piece of clean celluloid, slightly smaller than the gelatine, the celluloid itself resting upon a piece of cardboard or other porous material. The overlapping portion of the gelatine filter adhered to the cardboard, with the result that the screen dyed perfectly taut and even and was easily stripped off after dyeing. It was then cemented with Canada balsam between two pieces of plain parallel glass. Mr. McIntosh's preference was for a thick sample of balsam as conducing to freedom from air bubbles.

In conclusion the lecturer exhibited a number of examples of colour rendering of a group of flowers obtained on various plates, the most remarkable of which was that on the "Diford ordinary," used without any screen, which in its rendering of the reds was quite equal to the examples shown with screened orthochromatic plates.

In the subsequent discussion Mr. E. J. Wall objected to the green filter recommended by Mr. McIntosh for correcting the sensitiveness of plates of the average erythrosine type, but Mr. McIntosh, in disputing the objection, pointed out that no green dye was used in this filter, it was one of blue and yellow, and enabled him to give the necessary rendering to the greens. Mr. J. C. Warburg was surprised that the lecturer should use naphthol red, which was one of the few dyes which entirely cut out the red of the spectrum, but the lecturer pointed out that as the great majority of the plates which he had been discussing in reference to filters were insensitive to red this property of the dye in question was of no importance to him.

A hearty vote of thanks to Mr. McIntosh on the proposition of the Chairman brought the proceedings to a close.

CENTRAL TECHNICAL COLLEGE PHOTOGRAPHIC SOCIETY.—On Mr. R. J. G. Dowse read a most interesting paper on "Slides," Mr. Schultz in the chair. The author, after a preliminary remarks as to standard sizes, component parts of etc., said that there were several methods of making slides—bromide, gelatino-chloride, carbon, collodion, and albumen would confine himself to the gelatino-bromide and chloride processes. Having obtained the negative there are two getting the latent image on the lantern plate—by contact if it is the same size as required on the slide, or by reduction a camera, if the image is too large. A slide which is too de be reduced by two methods: (1) the well-known Howard reducer, which increases contrast; (2) ammonium persulphate reduces contrast. Thin slides may be intensified by bleaching mercury bichloride and re-developing. The author then d various toning processes. Gaslight plates may be developed tones by over-exposing and using a diluted developer, well re with ammonium bromide and carbonate. Slides may also after development, copper giving red tones, iron giving blue (Prussian blue), and gold giving blue-black to blue, and even was stated. Carbon slides are made by printing on carbon and developing as usual, but transferring to prepared glass of paper. The image must be much lighter than for a print, part of the image has to be transparent. Some slides were in the colours as supplied by the Autotype Company. For the finished slide, mask of black paper and cover glass t adhesive paper strip, tape, or even metal strip are employe numerous points raised in the paper were well illustrated by prepared slides. The author next referred to slides in colours by the Sanger-Shepherd and pinatype processes. Some lent slides in natural colours, lent by Sanger-Shepherd and C projected on the screen at the same time. After the pap slides lent to the society's exhibition by Mr. C. W. Tidm shown on the screen.

HOVE CAMERA CLUB.—The annual meeting of the Hove Club was held at the headquarters, Western Road, last week the presidency of Mr. A. R. Sargeant, J.P. The report a membership of 115 as against 125 last year. The committee r the death of the hon. secretary, Mr. W. H. Bone, and an ex-pr Mr. G. B. Woodruff, J.P. The balance sheet showed a bal hand of £10 9s. 7d., and this was adopted. Officers elected ensuing year were: President, Mr. A. R. Sargeant, J.P. presidents, Alderman J. Colman, J.P., Mr. W. A. Hounson Mr. A. W. English, Mr. C. Job, Mr. W. Clarkson Wallis, a E. E. Manwaring; hon. secretary, Mr. Stanley Read; hon. tr Mr. F. L. Jemmy; hon. auditor, Mr. C. V. Shattock; com Dr. C. S. Simpson, Dr. E. J. Spitta, and Messrs. L. A. Gill Mennich, F. J. Phillips, W. W. Palmer, G. W. King, and Foskett.

THE UNITED STEREOSCOPIC SOCIETY.—In connection with the of M. Victor Selb, vice-president of the society, Dr. S. Walsh gave a third social evening to the London members on the 2nd at his residence at Shepherd's Bush. During the evening interesting specimens of stereoscopic slides were shown am members, several of which were taken at recent outings co with the society. Attention was particularly called to M. novel stereoscope, also his three-colour transparencies, whic much admired by the members. Other slides worthy of not those of Messrs. S. W. Shore, F. Low, H. A. Miles, and a s hand-coloured slides and transparencies by Mr. P. Snow. The is fortunate in possessing some excellent workers in stereoscop a great improvement of work has been noticed in the n sets recently. It is mainly due to the helpful criticisms given members.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.—On Monday last, the members of above Society, Mr. W. F. Slater, F.R.P.S., senting Messrs. Kodak, gave his lecture and demonstrati "Development." The lecturer proceeded to show that by th method of time development, which is distinct from factori best result possible under the circumstances of exposure w tained. It was not possible to get out of a plate what w already there latent, nor did the addition of bromide to a dev for over-exposures improve matters, for that salt only des the gradation. An under-exposed plate, if developed as a co

one, will give as much detail and give as good a result as possible. The lecturer therefore claimed that a standard plate at a standard temperature, and developing for a fore-determined length of time according to the density of negative obtained, was the only proper method. Over-exposures which are very dense could be treated with Farmer's reducer, which, by bringing the half-tones more than the high-lights, would then give excellent printing negative. A plate having received a certain exposure, no amount of tinkering with the developer would make improvement in the final result. The amount of detail was determined by the exposure and nothing else. It was a mistake to suppose that any particular developer has more power in getting detail out of a plate than another, if properly used. The lecturer then proceeded to develop a spool of film in the Kodak operation being simplicity itself. The film was placed in a tank containing pyro-soda developer at a temperature of 60° Fahr., and developed for twenty minutes, the only attended-for being an occasional turn up of the tank. At the end of the allotted time the film was taken out and fixed, and then brought round for inspection, the result being technically all that was desired. At the conclusion an animated discussion took place as to the merits of time development for subjects having strong contrasts also for pictorial work, but Mr. Slater maintained his opinion that by the method just demonstrated all that the negative could be brought out, and in the best possible

## Commercial & Legal Intelligence.

**VENTNOR BANKRUPTCY.**—Mr. Alfred James Ford, photographer, of Ventnor, appeared for his public examination at the Court of Bankruptcy, Isle of Wight, Bankruptcy Court, last week, before Mr. Justice. The statement of affairs showed a deficiency of £411 and no assets. The debtor attributed his failure to bad competition, and insufficient knowledge of the trade. In reply to questions put by the Official Receiver, debtor stated that he had been in business just over three years ago. He had never been in business before, and knew nothing about the photographic business. He had received £610, given to him by his parents, and he spent that, chiefly in alterations and additions to the premises, in the erection of a studio, that money being really sunk at the time. He had been losing money right from the start of the business. Liquidation was concluded, subject to the signing of the short-terms.

### NEW COMPANY.

**WESTMINSTER PHOTOGRAPHIC EXCHANGE.**—Capital £10,000 (£1). The business carried on by E. E. Edwards and A. J. as the Westminster Photographic Exchange. No initial public subscription. First directors (not less than three nor more than five): E. E. Edwards, A. J. Leather, and J. E. Hodd (chairman). Qualification of first directors, 100 ordinary shares. £50 each per annum. Victoria Street, S.W. (93,480.)

## News and Notes.

**MR. HARRINGTON,** who, with Mr. C. R. Unteutsch, is the owner of the well-known New Zealand firm of Harrington and Co., is on his way to England, via Japan and America. He is to reach London about July 12, and will interest himself in the photographic business of the New Zealand market. Previous to his departure from Sydney Mr. Harrington was the guest at a "bon voyage" picnic given to him by his employees, by whom he was accompanied with a handsome travelling trunk as a memento of their

**RAINES SERVICE.**—Messrs. Raines and Co., of Ealing, London, have issued their 1907 list of prices, which, as seemed inevitable, is entitled "The Raines Service." We are glad to have the opportunity of drawing attention to the consistently high-class standard maintained by this enterprising firm in its work for professional photographers.

**KILLING FORKIES** (in last week's "Answers to Correspondents").—These pests are known as earwigs in the south. "Forkies" is a short form of "forky tails," and I think pretty general over Scotland as their name. "G. G. G." might try some garden insect destroyer, or wash out his place with carbolic soap.—SCOTTIE (Glasgow).

**MR. WOODHOUSE PARKINSON,** secretary of the Whitby Camera Club, and whose camera work has wider recognition than that afforded in Whitby alone, has opened Waterloo Studio, Flowergate, as a high-class portrait studio. Mr. Parkinson has devised and carried out a scheme of lighting which will enable him to work under the best possible conditions, and he has the advantage of being an experienced artist in both water colours and oils, which will enable him to bring to bear in his portrait work a knowledge of composition and posing, which will be very useful. The Waterloo Studio is the one occupied for so many years by Mr. F. M. Sutcliffe prior to his removal to his present premises.

**"THE PLANET."**—The issue for June 1, in addition to much interesting information on current topics relating to politics, music, art, etc., contains four illustrations of typical scenery and life in New Zealand, which are the first of a series, entitled "Greater Britain."

**THE PHOTOGRAPHIC SURVEY AND RECORD OF SURREY.**—On Saturday, June 8, the members will hold their second annual photographic visitation, under the leadership of Mr. Hector Maclean, when, by special permission of the Duchess of Marlborough, Deepdene will be visited and photographed. The house itself contains many objects of photographic interest, notably the Etruscan room and the antique statuary, whilst the views in the grounds are remarkably fine, and some of the "specimen" trees and contents of the glass houses will doubtless come in for their share of attention, especially from members of the nature history section. In the afternoon it is hoped to visit Camilla Lacy, a historic mansion in the same neighbourhood, but should this not prove possible, a suitable arrangement of an equally interesting character will be substituted.

**"CRUTCHES TO HELP CRIPPLE CHILDREN."**—A publication under this title has been issued by Messrs. Bemrose and Sons, Ltd., 4, Snow Hill, London, E.C., at 1s., in aid of the Lord Mayor's Cripples' Fund. The entire profits are to be devoted to this admirable object, yet the purchaser who expends his shilling on it will surely feel that for once charity comes easily to him, seeing that among the literary contributors are numbered W. S. Gilbert, Alfred Sutro, G. R. Sims, Manville Fenn, Max Pemberton, and W. L. Coultney. The illustrations include three-colour reproductions of modern works of art to a considerable number.

**THE "TICKA" TITLE COMPETITION.**—Messrs. Houghtons have issued a series of twelve humorous postcards, specially designed for them by Mr. Charles Harrison, the well-known "Punch" artist. These illustrate the use of the "Tickka" camera in various parts of the world, and prizes of two guineas each are offered for the best title for each picture. Each title should either introduce the word "Tickka" or in some way be applicable to that instrument. The cards may be obtained free from photographic dealers in all parts of the kingdom.

**DR. C. E. KENNETH MEES** has been elected a member of the permanent committee of the International Congress of Photography, which is occupied in the consideration of plate speeds and other photographic measurements.

**MESSRS. O. SICHEL AND CO.,** of 52, Bunhill Row, London, E.C., announce that they are now showing a large selection of photographic accessories of all kinds, including a seven-piece accessory, nine-piece gate accessory, 9ft. pillar with base, extending settees, etc., an inspection of which will doubtless prove of interest and use to professional photographers.

**FRAUD IN HAWICK.**—At Hawick recently, Mary Morrison or Douglas pleaded guilty to fraudulently obtaining framed photographs from a shopkeeper in Bourtrees Place. It was stated that she had represented that her husband was going to San Francisco, and desired to take with him some views of Hawick, which she got away with her, and promised to pay for them next day. Having been several times convicted of similar and other offences, the accused was sent to prison for thirty days.

**FOR THROWING HYDROCHLORIC ACID** upon Mr. John James Avery, photographer, living in Sandringham Road, Hackney, Lillian Sarah Woodcock was sentenced by Mr. Justice Bigham to twelve months' hard labour at the Central Criminal Court last week.

MR. ALFRED WATKINS.—We are glad to be able to report that the President of the Photographic Convention of the United Kingdom is recovering from the recent motor accident. Mr. Watkins writes us with his own hand that he is able to come downstairs on a crutch, that his general health is good, and that he is on the way towards being able to walk again. Our readers, we are sure, will wish Mr. Watkins a speedy and complete recovery.

ARTIFICIAL LIGHT DEMONSTRATION.—We are asked to announce that a demonstration of the Schmidt Jupiter flash lamp, which has attained a wide circle of supporters among professional photographers in Germany, will be given at Belgrave Chambers, 72, Victoria Street, S.W., on June 20. On the same occasion an opportunity will be given of inspecting many examples of the use of the lamp in the shape of portraits, figure studies, and groups. Further particulars may be had from Mr. A. Strauss-Collin, Bush Lane House, Cannon Street, E.C.

THE "RAJAR" CAMERA, offered monthly by Messrs. Rajar, Limited, of Mobberley, Cheshire, for the best print on "Rajar" P.O.P., has been awarded to Mr. C. F. Emeny, 8, Gainsborough Street, Sudbury, having been judged the best received during May. The paper on which the print was made was purchased from Mr. James Brown, chemist, Sudbury.

## Correspondence.

\*.\* Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

\*.\* We do not undertake responsibility for the opinions expressed by our correspondents.

### A WINDOW TILTING TABLE.

To the Editors

Gentlemen,—I see in the "B.J." recently a reference to a device to enable one to photograph from a window without a tripod by setting up two boards, which are, after all, unhandy to carry about. Some thirty years ago I used another device for the same purpose, which I carried in my pocket and could use anywhere where the English windows (rising) were adapted, but not so easily with French windows opening on the inside. On the lower part of the front of the camera I had a nut inserted with a thumbscrew to fit

Fig. 3.

Fig. 1.

Fig. 2.

in it (Fig. 1). Then I had a piece of brass (flat) made about 8 to 10 in. long  $\frac{3}{4}$  to 1 in. wide, and  $\frac{1}{4}$  in. thick, and in the middle of it a slot made in which would run nicely the screw above mentioned (Fig. 2). This brass piece would rest on the window sill, and the bed of camera on the window frame, and make a perfect tripod (Fig. 3). I could raise or lower the front of camera at will, using the slot and screw.—Yours very truly,

A. LEVY.

4, Avenue Pinel, Asnières (Seine).

May 19, 1907.

### BLISTERS IN BROMIDE PRINTS, AND THEIR ELIMINATION.

To the Editors.

Gentlemen,—The interesting discussion which has been going on for some time past on the subject of the blistering of bromides leads me to offer a suggestion which, if acted upon, would, I believe, put an end to the evil.

There is abundant evidence in what has been lately written on

the subject to show that blisters are nearly always present in one might call an "embryonic form" in bromide papers, but they only show themselves under certain conditions of treatment.

The conditions favourable to their development seem unmissably to indicate their origin, and, if so, the certain means for their avoidance. All the evidence points to the blisters arising from excessively minute air-bells imprisoned in the film of gelatine. Under ordinary conditions the hardening of the gelatine around such bubbles of air so effectually isolates them and binds them down their presence is not suspected. This is the condition of the so-called "non-blistering paper" of the ordinary worker. But when more drastic methods of treatment are brought into use, such as sulphide toning and the like, there is probably a weakening of the mechanical resistance of the gelatine. Under such conditions contained air would be free to move, and when many minute bubbles are in close proximity one with another they would tend to coalesce, forming one larger bell—to wit, a "blister."

The facts that softening agents, soft water and the like, softening chemicals tend to "produce" blisters, and that hardening materials such as alum tend to give immunity from them, all point to the above explanation as being, in the main, correct.

What, then, is the remedy? Eliminate the air from the emulsion, and the evil will be cut off at its source. But how is this to be done? Before seeing how to get rid of anything it is well to ascertain how one came in possession of it. Where does the air, which I allege to be in the emulsion, come from? It comes from the water with which the emulsion is made. Water naturally contains a large amount of air. Freshly drawn from a tap or spring generally contains sufficient to form visible bubbles on the inner surface of the glass containing it. Water can easily be freed from air by boiling it, and if emulsions were not viscous they could be made of air by using water which has been recently boiled through for a few minutes. But the viscosity of the emulsion and the readiness with which water reabsorbs air would go far to neutralise the benefit of using boiled water. The necessary stirring and agitation of emulsification and the agitations of washing would be enough to induce quite an important re-absorption of air.

The only true remedy for the evil, then, is *pumping*. When emulsion is otherwise ready for coating, it should be placed, quite warm, in a cylinder fitted with an air-tight cover and connected with an air-pump so as to produce and maintain for about half an hour a vacuum of about 26 to 28 in. of mercury. Under these conditions the air contained in the emulsion would expand into bubbles large enough to rise to the surface, where they would form a sort of scum.

Paper coated with an emulsion so prepared would, I believe, be free of blisters, no matter what sort of treatment it received in manipulation.

NELSON K. CHERRILL.

### CINEMATOGRAF EXHIBITIONS IN THE EAST.

To the Editors.

Gentlemen,—In your issues of December 28, 1906, and April 1907, I read both letters under the headings "Britishers. W. Up," and "Britishers Not Asleep." As an Englishman, and a resident of this town for over twenty years, both letters interested me very much.

From the enclosed you will glean that neither of your correspondents is quite correct in his statements, one as regards British shows, and the other as regards charges for seats.

I have visited most of the shows that have visited this town, and am quite sure that there was no appreciable difference, and quite sure that on no occasion have I paid less than \$1.50 for a seat, and sometimes \$2 (value of the dollar 2s. 4d. now). "See people coming" would very soon prevent their shows being crowded, which they are nearly every night.—Faithfully yours,

W. T. WOOD.

Kuala Lumpur, Selangor, Federated Malay States,

May 8, 1907.

[The article referred to by our correspondent criticises the prices of previous writers, and concludes as follows:—"As far as our experience goes, the prices here range from \$2 to 25 cents. The risk attendant on this business are so great that we cannot conceive any show ever paying its way at a maximum charge of 50 or 30 cents."

mission. There have been numerous cinematograph shows lately, and the charges have in each case been about the same. We have also, however, been much upon a par, though probably the films we have seen was one run under European supervision. Particular show had electric fans, a feature which distinguishes it from any of the others. As far as an outsider can judge, these shows get their plant and films from the same source, and are as absurd to condemn the European ones as inferior to those of the Asiatic competitors. They are all on about the same level, and no one takes seriously the suggestion that any of these are superior to those of the London halls."—Eds., "B.J."]

### A WAVE OF ORTHOCHROMATISM.

To the Editors.

Sir,—In reference to your footnote to the report of my paper, whilst I am open to admit that Mr. Stevens' flower studies are beautiful, I would point out that so far as I have seen of them they are composed of white blooms, and even these would, I think, have been much improved had Mr. Stevens been able to use colour-sensitive plates with properly adjusted filters. One can take white flowers, obtain the texture which is of so much importance in this work upon ordinary plates, and at the same time lose all the value of the green stem. Again, was not Mr. Stevens about the only worker who did this class of work in those days, an exception which proves the rule?—Yours very faithfully,

ERNEST HUMAN.

Park, June 2, 1907.

To the Editors.

Sir,—The points, as I understood, raised by Mr. Salt, in your issue of the 10th ult., were:—Is it desirable or otherwise to use ortho plates and filters? Whether an ortho plate under every condition without filter will do all that an ordinary plate is capable of. Nos. 2 and 3 of the landscapes I sent you I think proved that under those conditions the ortho and filter gave all that was possible, and no process effect. The No. 1 seascape I do not think has been a whit better on ortho, and it could not possibly be taken with a filter from a moving steamer in 90th of a

second, and shall be glad with your comment on them, as they are of the same subject taken simultaneously, both on ortho and on one with and one without a filter. There is a variety of results in the flowers, with differing shades of green in the leaves, etc. I have numbered these 1 and 2, and should like to know which you consider the best rendering of the whole subject. I have already given my experience of the ortho plates for landscape work without a screen, and it seems to agree with that of your correspondent, "A Colour Painter." I very much question if the filter does not always cause some loss of atmosphere, which is, of course, of little importance. Still, I am open to instruction.

PROFESSIONAL.

There is very little difference between the two photographs, but I should judge No. 1 to be a slightly better rendering.—Eds.,

### DARK-ROOM ANÆMIA.

To the Editors.

Sir,—I notice your article re chronic anæmia caused by dark-room work. You say that you have not come across any case like mine. I am sorry to say that I am exactly such a case, having been in two good situations for that very reason. I have 15 years' experience as enlarger, and experience in general dark-room work, but had to give it up by my doctor's orders, and took as a printer in P.O.P., C.C., platinum, etc., in the open air, trying to regain my health that way. Whenever I have any dark-room work to do I do it in the evening, as I develop films, etc., for 4 or 5 hours. I think four to six hours a day quite long enough for a dark-room worker, and it should be paid much better, as it is in the system when middle age comes on. I refer, of course, to those who spend their whole time as enlargers and dark-room workers.—Yours faithfully,

G. GILKES.

1, The Villas, Feltham, Middlesex.

## Answers to Correspondents.

- \*<sup>a</sup> All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \*<sup>b</sup> Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \*<sup>c</sup> Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \*<sup>d</sup> For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

### PHOTOGRAPHS REGISTERED:—

- W. W. Sanderson, 8, Kensington Terrace, Newcastle-on-Tyne. Photograph of Professor Hubert von Herkomer.
- E. Wilson, 18, Gloucester Road, Boscombe, Hants. Photograph of H.M.S. "Dreadnought."
- F. Sadler, 41, Ridley Street, Birkenhead. Five Photographs:—A View of Lake in Birkenhead Park. A View in Bladon Woods, Birkenhead. The Boat-house in Birkenhead Park. The Birkenhead Town Hall. The Congregational Church in Oxton Road, Birkenhead.
- S. H. Greenway, 27, Abington Street, Northampton. Photograph of the Northampton County Cricket Club.
- W. H. Page, The Grove Studio, Ventnor. Photograph of the Rev. B. W. Colquhoun, Vicar of Ventnor.
- F. A. Cooper, 32, Hamilton Square, Birkenhead, Cheshire. Five Photographs of John Bull.

R. R.—The Japanese papers are:—"Shacin Shimo," 4, 10 ch. St. Kobikicho; "Tokio and Shasin Showa," 18, Neihome Minami Sukumacho, Shiba, Tokio; but we cannot say which is the better for your purpose.

OWNERSHIP OF NEGATIVE.—A gentleman instructed me to photograph a group, and ordered a number of copies from me. Now he wants to claim the negative as being his property, and will only pay a trifle for it. Being an amateur photographer he intends taking further prints from it, and so save the expense of giving me the order. Now what I want to know is, does the negative belong to him or me?—ENQUIRER.

The negative must remain in your custody unless you specially contracted for its delivery at the time of taking the order. Prints may be taken from it only at the order of your customer.

GLAZING P.O.P.—Is there any known method by which to glaze P.O.P. prints after same are trimmed and mounted without injuring the mounts? If so, I should be glad to know, as it would doubtless be very useful for postcards as well. Would you kindly describe the method as to how to apply and use same, and where to obtain it?—M. G.

Prints may be given a higher surface with a hot burnisher, such as supplied by any of the large dealers for regular professional use. Messrs. Fallowfield, for example, will send you particulars.

SELF-TONING.—1. Having noticed that my gaslight prints showed signs of fading in a very short time, I consulted the representative of the firm from whom I obtained the paper. He said the cause of my trouble was the way I mixed the acid fixer; the chemicals should not be mixed with warm water, as that caused sulphur to form in the bath. In your article in this week's "B.J." you advise the use of warm water in mixing the acid fixer for bromide paper. Will you kindly give me a reliable way of mixing the acid fixer, and also what to avoid which is likely to affect the permanence of gaslight and bromide prints? 2. Also can you tell me what is the cause of P.O.P.s which have been toned to a rich chocolate after a few months or years, turning to a warm yellow in the shadows? Is it due to insufficient fixing, or is it due to something in the toning? The sulphocyanide bath was the one used in all the cases I have noticed. 3. Do you consider self-toning paper sufficiently permanent to warrant a good-class professional photographer using it?

1. If the chemicals are mixed in the correct order—that is, the hypo and sulphite first, and then the acid and alum, there is no harm in using warm water. But on no account should acid and alum be mixed with the hypo until the sulphite has dissolved. 2. We cannot say we have any experience of the defect occurring

after so long an interval. We have known of a somewhat similar effect being produced immediately with sulphocyanide baths. We are inclined to attribute it to lack of ripening of the bath. 3. If a sufficient time is given for fixing, i.e., such a time and strength of hypo as would ordinarily be thought necessary for P.O.P.

- D. F. H.—You have done exceedingly well under the conditions you mention, but teaching yourself entirely from a book—however good—is slow work. Still, read all you can, see all you can, and take every good hint that is given from practical workers. Your being in the country is no bar to your learning; postal lessons are quite effective, and would advance you greatly. You should certainly persevere, for you have a delicate touch and colour sense, but no particular strength in modelling, and your shadows are much too cold in tone, especially the flesh shadows. Your background is nearly all the same colour; break it up with variety of tints, it is too monotonous. Soften your sharp edges more, and in a very short time with careful study you will undoubtedly make a considerable advance.

RETOUCHING AND OPERATING (Reply to "Anxious.")—Your work in both branches is weak but promising—very promising as far as the retouching is concerned, but you want guidance. The female portrait presents better results for retouching and operating than the man, but your lighting is very defective, and you really require practical advice in both arts. With regard to your retouching, use a finer and longer point, and try to get your effect with less labour and lead. Grade into the half-tones and feature lines, with lighter weight on the pencil, for variety in touch is everything if you wish to avoid a merely mechanical and studied stipple. Use a proper background—they are very cheap—when taking sitters, and your work will then present a more professional appearance. We make it a rule never to suggest the probable salary a correspondent may secure, as we have no wish to set a standard rate. Make the best terms you can either by answering advertisements or advertising in our columns.

SHORT EXPOSURES.—Can you inform me as to how a photograph of an object is taken in 1-1,000th part of a second? Many advertisements state that the camera is fitted with a shutter working up to 1-1,200th of a second. I have two cameras fitted with focal-plane shutters and first-class lenses—one lens works at  $f/4.5$ , the other at  $f/5.8$ , and have never been able to get a good negative, exposing to 1-200th of a second. I have a list of plate speeds supplied with the Wynne meter; the fastest speed is given at  $f/1.11$ . If it takes the sensitive paper two seconds to change to the index colour, working at  $f/7$ , the exposure is about 1-128th of a second; at  $f/5$  the exposure would be about 1-256. It is very seldom that the sensitive paper will change to the index colour in two seconds, and I find that I have to give about one and half times the exposure given by the meter to get a good result; therefore I am at a loss to know how photographs are taken in 1-1,000th part of a second as advertised, and it seems to me that a shutter working less than under 1,300th of a second is a useless attachment working to less than under that amount.—W. T. WOOD.

It is not claimed that such short exposures will give properly exposed negatives, and they are possible at all only under the very best conditions of light, and with a large aperture. But you should have no difficulty in getting fairly well-exposed negatives at  $f/4.5$  in 1-1,000th second, using a pyro-metol or rodinal developer, or any other developer about half or third strength. We advise you to make test exposures, neglecting the meter indications. Though the results will not be fully exposed they will no doubt be equal to the average work at such short exposures.

- S. E.—We do not quite understand how prints bleached in such a strong solution can intensify. This is quite contrary to our experience and that recorded by Mr. Douglas Carnegie in the "Almanac," p. 679. We think that the real trouble lies in the shadows apparently blocking up on drying, as one of the prints sent us, when wetted, was extremely rich and juicy in those parts, though when dry quite devoid of detail. The best strength for the bleach is about 1 oz. of bromide,  $\frac{3}{4}$  of ferricyanide, to water 30 oz., and the sulphide should be about 100 grains to 20 oz. of water. If there is actual intensification then the only remedy is to expose fully and develop for a

shorter time, so as to obtain a less intense print at first, then bleach. But as we have stated above, we doubt the intensification, and would suggest that wetting one of the prints will prove to our correspondent that we are right in our advice as to the print blocking up on drying; and if so, pain the print with the varnish recommended on p. 811 of the "Almanac" will improve matters. It is needless to state if the prints are not thoroughly bleached there would be intensification, for one would have the brown sulphide deposited on the black silver image. A hasty test of one of the prints sent rather points to this.

- J. A. AND SON.—Alfred Underhill, 32, Clarendon Road, Croydon, Surrey.

LENS QUERY.—I shall esteem it a favour if you will kindly give me a little information about a C.D.V. portrait lens I have, marked as follows: "No. 556. Vallantin Optin. de 1840 à 1845. Contrme. des Ateliers des MM. Lerebours, Paris." There are stops at all, neither a place for same, and I should like to know the aperture. Diameter of lenses 1 $\frac{1}{2}$  in., distance (inside) between front and back lens about 2 in.—LENS.

The lens is probably not a C.D.V., but the old quarter-plate lens, as it is not fitted with stops, which the C.D.V.'s usually have. It has evidently been made many years. If there is no fitted phragm between the glasses, the aperture is, of course, 1 $\frac{1}{2}$  in. If there is one, you can easily measure its aperture, which will give you practically the effective aperture of the instrument. Vallantin's lenses, at one time, were in fair repute, and so were Lerebours'.

- H. H. O. F.—We will take the matter up and report.

WHITE PAINT, ETC.—1. I shall be glad if you can give me information how to make white paint to block mounts. 2. I have iron dishes, 30 x 25, they seem to rust, can you give me remedy.—BOUDON.

1. The white paint used is, we believe, merely Chinese varnish or oxide of zinc rubbed up with gum water or dextrine solution. 2. Dry the dishes thoroughly after cleaning off all rust with emery powder, and then give them a coat of Brunswick black or one of the numerous bath enamels obtainable at any oil merchant, allow to dry thoroughly, preferably near a fire, and then give a second and third coat in the same way.

AXIS.—There is a French patent (No. 339,216) of the Neue Photographische Gesellschaft for a similar process. Bromide plates are bleached in solutions of copper salt, containing ammonia or other chloride. You will find a brief note in the current "Almanac," p. 792.

- A. MACBEAN.—The Lumière N. A. Company, 4, Bloomsbury Street, London, W.C., can supply you.

WORKER.—Whole-plate is the best size. We can only refer you to the "Almanac" for the various cameras.

AMERZ.—Weak acetic acid.

E. P. C.—We can understand ink rubbing off, but it appears to be quite bleached the prints. We should advise you to change the brand.

ANXIOUS.—The print is a real photograph. It is an ordinary bromide, it seems to us. You say the hot water has had no effect, but evidently it has loosened the hardened film on the card.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## EX CATHEDRA.

### The Reflex Exhibition.

By the time these lines appear the exhibition of reflex cameras and photographs at the house of the "B.J." will have been opened, and may be visited by the public until July 6. A large proportion of our space this week is devoted to a description of the apparatus, not a few items of which, it is true, would need more lengthy reviews were they alone being dealt with. In describing, however, a number of cameras of the same general design, the only course to pursue is to emphasise the different features, otherwise the notices would become indescribably wearisome from repetition. For the three articles on reflex work which immediately follow "Ex Cathedra" we would ask a careful reading, as well as for two others by Mr. Arthur Marshall, F.R.P.S., and Mr. F. Martin Duncan, F.R.P.S., which we shall publish in next week's issue. The details of the makers' apparatus will also be found to contain notes by the way on reflex work of interest even to those who have not a particular camera in mind.

\* \* \*

### To Visitors.

To those who have some particular requirement in view in acquiring a reflex camera, or have set some definite limit to the money they are prepared to spend on an instrument, we would be allowed to offer a word of suggestion, namely, that they should carefully go through the descriptions in this issue, and on their visit ask to be shown the apparatus which most appeals to them. They may with advantage obtain also in the meantime the maker's circular, as in many cases there are accessories which space forbids us to enlarge upon, but which nevertheless affect one's opinion of the camera. The exhibition, which at the last moment has been reinforced by one or two cameras from houses not previously announced, is open daily from 10.30 to 4.30, and on Saturdays from 10.30 to 12.30. There is, of course, no charge for admission, but visitors are requested to inscribe their names and addresses in a book on entering. The actual apparatus is, of course, not for sale during the exhibition, and enquiries as to purchase of similar articles should be addressed to the respective firms.

\* \* \*

### Testing Shutter Speeds.

Mr. Arthur Payne describes, in the "Photographic Monthly" for June, what he claims to be a new practical method of testing shutter speeds. Briefly stated, the method depends on the comparison of the results obtained with a small aperture and an accurately timed longer exposure with those produced with a large aperture and what should be an equivalent shutter speed. Thus he points out that five seconds at  $f/64$  is equal to all practical intent to 1-15th second at  $f/8$ , hence if the shutter is correctly marked for 1-15th second, two plates exposed in these differing condi-

tions should give the same result. For fuller details the article should be consulted. This does not seem to us to be an altogether promising method, as the results depend on the visual comparison of two negatives exposed on natural scenes. If the results happen to differ materially simple inspection will give very little information with regard to the amount of the error in the shutter speed. If, however, the exposures be made in a series of graduated densities, it should be possible to estimate the error with a near approximation to accuracy. We suggest this variation of Mr. Payne's method as one well worth trial.

### The Treatment of Bichromate Sores.

\* \* \*

At a recent meeting of the New York section of the Society of Chemical Industry, Dr. Riederer, in dealing with the subject of bichromate poisoning, stated that the men employed in the chrome works were cured by being moved to the lead works. Obviously, the remedy is almost, if not quite, as bad as the disease, as lead poisoning can be easily set up. He suggested, therefore, another method, which consists of treating any sore with a 5 per cent. solution of sodium bisulphite. Nine months' experience of this method have proved very conclusively the efficacy of the treatment, and workers in the chrome plant are now provided with the bisulphite solution for washing purposes after work. The use of bisulphites or metabisulphites for destroying the traces of bichromate in various photographic printing processes is, of course, well known. The use of the same salts by those who are sensitive to bichromate will, if Dr. Riederer's statements are correct, completely obviate this trouble.

## REFLEX CAMERAS.

### I.

THE present exhibition of reflex cameras at our offices must surely be regarded as a demonstration of the attraction of this type of camera for a number of makers, and of its adoption by workers who are among the leaders in different branches of photography. The greater attention which the reflex camera has received of late is no doubt the result of the high perfection to which the instrument has been brought by makers who were pioneers in its introduction, as well as of the clearer recognition by photographers of the advantages of the mirror method of full-size focussing. These latter, we find, are not so well understood as they might be, and we propose, therefore, in this first article of a short series, to consider briefly the aid which the modern reflex grants to hand-camera photography.

Before we say anything of the more important advantages of the reflex camera, we should mention one point which bears indirectly only on the quality of hand-camera work done with it, namely, the impossibility of inadvertently making an "exposure" with the lens covered—an act of absentmindedness or haste of which the user of an ordinary finder camera is bound to be occasionally guilty. The mirror automatically puts things right in this respect at the start, and leaves the user to look only after the setting of the shutter and the uncovering of the plate or film. In certain makes of camera this check upon the user is carried further by the provision of a blocking mechanism whereby the shutter cannot be re-wound after an exposure until the mirror has been depressed. Thus, while this feature of the reflex is not a positive facility, it is a valuable auxiliary, as it leaves the hand-camera user with one (or two) fewer things to think about, with the result of a higher percentage of effective exposures.

But it is in the ease of focussing and arranging the subject on the ground glass that the power of the reflex is

most fully in evidence. One might almost have assumed that there was no need to emphasise these properties of reflex type of camera, yet, so hard do custom and prejudice die, that it is not uncommon to meet hand-camera workers who will not concede any advantage to the size focussing over the methods of scale focussing on judgment of the distance of the subject. Granted after a somewhat lengthy course of practice a high degree of skill in judging distance is attained, it is extremely rare to find it very wide in its scope; it is usually confined to a certain class of subject, and as soon as a subject in different surroundings is approached the power of accurate judgment of distance falls off, and may leave the worker astray. We believe this fact is generally recognised by those familiar with hand-camera workers. Walter Kilbey, who writes after a long experience of hand-camera work, says on this point in "Advanced Hand-Camera Work":—"The man who has been used to working in the streets, and has acquired his knowledge of distances there, will be rather at a loss when working in an unconfined situation such as an athletic sports ground and will be very liable to judge distance incorrectly for this reason: that a given distance in a long street appears greater than in the open field, and *vice-versa*."

Then again, although such skill in distance-judging can be attained as to ensure fairly certain work at the average distances of 10, 15, and more feet up to an infinity of 100 ft. in the case of a lens of about 5 in. working at  $f/16$  power attainable by ordinary beings is totally insufficient in the two distinct conditions of (a) photographing objects nearer than 6 ft., and (b) using a lens of large aperture, extra-long focus. The first of these two conditions is not common as the second, but is nevertheless no imaginary case. In the ordinary run of tourist photography, interesting objects, tablets, bits of ornament, etc., are met with which are beyond the powers of the ordinary hand-camera, unless converted for the nonce into a microscope, but yield immediately to the reflex.

In regard to the tax which the modern large aperture lens lays on the skill of the hand-camera worker, it will be remembered that the judgment of distance must be increasingly exact as the lens aperture is increased, or as the greater focal length employed. A glance at any table of "depth of focus" will show the narrower limits within which accurate focus is obtained, and yet—and here is the point of importance—modern hand-camera work involves both these limiting factors. Our impetuous aesthetic standards will have none of the semi-exotic negatives which passed muster in the past (large aperture or of the rather wide angle given by the lens of "normal" focus (long focus). These are the views of the tourists; the non-artistic public is even more exacting in its demands for photographs of events, social, sports, and what not, the photography of which necessitates extremes in the use of large aperture and long focus lenses. The only way to successful work in these conditions, we repeat, is in the reflex camera. To give but one example of the everyday application of the methods referred to, let us quote Mr. Arthur Marshall in "The Vagabonds in Friesland," wherein he describes his method of tourist photography at the rate of about fifty pictures per day with a reflex camera. Writing of the 5-in. lens he says:—"A useful though costly accessory to a camera is a first-class 12-in. focus lens working at  $f/6$ . Many of the pictures in this book were taken with this lens. Of course, the single combination of the small lens gives an image as large, but the rapidity of the larger lens is useful in cases where the other would be useless." Mr. W. Thomas, in the article on another method for the sake of orthochromatic rendering, possible with a hand-camera only under the above conditions, de-

ival at the same method of work. Neither of these workers, we venture to say, would expect a reasonable percentage of good negatives in any hand-camera of the reflex type.

There is still one other point which we must not omit—we postpone some notes on reflex cameras them- until next week, and that is the perfect certainty the reflex imparts to the use of a rising front on a camera. No other device for the purpose of showing a picture obtained on the plate when the lens is closed and there have been some elaborate ones—can be

compared for certainty and simplicity with the reflex camera. Even as to this point we have sometimes been told that a hand-camera is none the worse for the lack of a rising front. You tilt the camera, and in making a reproduced negative, enlargement, or lantern-slide, you correct the convergence of the lines. Apart from the trouble of these operations, there is great danger of dwarfing the subject, even though the lines are parallelised, a fact which does not appear to be generally recognised even by champions of the reduction of the hand-camera to the simplest elements.

## THE VALUE OF THE REFLEX CAMERA IN PROFESSIONAL PORTRAITURE.

The following article, Mr. Gordon Chase, the well-known professional photographer, of Tunbridge Wells, describes his own use of the reflex camera for studio portraiture. Mr. Chase employs an adaptation which allows of silent, short time exposures, and speaks appreciatively of the method.—Eds. "B.J."]

RELY no photographer has ever spent a day's work in a studio, occupied in his regular business of portraiture, without having brought before him the advantage which would be to his work were some ready means at his disposal for the precise effect obtained upon his ground-glass at the moment of exposure. It is perfectly true that in the ordinary course of posing a sitter almost any amount of facial movements is permissible, and even the pose itself may be modified

that I have installed a camera of this type in my own studio for any children portraiture that comes along. The stand, illustrated on this page, I made myself from my own design. The camera is a half-plate Adams "Videx" pure and simple; but to avoid

The Author's Camera Stand for Reflex Studio Portraiture.

at the negative suffering from any lack of sharpness. Yet, the limits within which a sitter must be kept in order to secure sharpness in the negative are comparatively narrow, and it is no easy matter for a photographer to avail himself of a variety of poses, particularly in the case of children, if they are possible. For some time past I have been experimenting with a reflex camera for studio use, inasmuch as an instrument of this description obviously solves the problem which I have stated above. The results have been so far satisfactory

The Camera in Use.

the sound made whenever the focal-plane opens and shuts at time of exposure I decided to remove sky-shade and fix on a pneumatic shutter, which, beside being a shade for instantaneous work, would silently expose all time exposures. The focal-plane makes just the same sound at instantaneous, but it is

over before it affects the sitter. When using it for time the focal-plane shutter is set at time, the blind wound up half-way to leave opening opposite plate and velvet shutter closed. The "antinous" release is pressed and the mirror rises without affecting the focal-plane blind, and leaves the plate ready for exposing. At this stage the camera is the same as an ordinary one being exposed by ball and tube, and any exposure can be given.

I might add, for any "At Home" portraiture I take the "Videx," no tripod, stand it on a small table, and use it as a reflex, only using the pneumatic silent shutter instead of the focal-plane, unless out of doors, in which case I use it at "instantaneous." The lens is a rapid "Uno-focal" anastigmat, working at  $f/4.5$ .

The pictures which are included in the collection of reflex camera work at the *British Journal* offices have the backgrounds purposely selected, ranging from a red plain one, dull black window accessory, to a plain cream one, in order to give an idea of the difference which results in the negatives; but it will be seen that they all come up with sufficient detail and exposure.

If I were asked what were the chief advantages of the reflex camera from the professional photographer's point of view I should say, first, and most important of all, rapidity. One keeps one's hand on the focussing knob and the other holds the "antinous" release, and I cannot imagine a more rapid transition from a fleeting pose or expression to its fixation on the photographic plate.

Secondly, portability, compared with the ordinary studio model. The reflex is certainly very much lighter and more convenient, and it disposes of that bane of the professional studio, the focussing cloth.

Thirdly, but very little experience is needed to convince the user of the reflex camera of the enormous facility which it affords as regards focussing. Scarcely a single child sitter comes to one's studio but what some adjustment of the plate is necessary before the final exposure is made. In the case of the ordinary camera three movements are necessary, in the case of the reflex only a single adjustment of the focussing pinion.

As arranged in my own studio, there is one advantage in the reflex camera which certainly deserves mention, and that is the perpendicularity of all the lines in the picture; the camera is always kept vertical; there is no swing back, and there is no necessity to stop down the lens. As arranged also in the draw-

ing, the camera can be placed within sixteen inches of ground, a great advantage in the case of little children who taking portraits showing their legs and feet. Even if an ordinary studio camera be placed at a low position, the photographer finds considerable inconvenience in focussing upon the vertical so, whereas when working with a reflex the position is the most convenient conceivable.

However, in all expedients for simplifying the photographic work the proof of the pudding is in the eating, and it shows therefore interest any of those whose inclination is towards

A Specimen of Studio Portraiture obtained by the Reflex Method. This portrait, with a number of others, is shown in the Reflex Exhibition.

reflex camera for their own work if I say that using a changing box containing twelve plates, one need not leave the studio during sitting—it is generally whilst slides are being changed the best poses are noticed—and can generally rely upon being able to submit about ten proofs for selection without throwing out first the usual percentage of "moves," which cannot be avoided in ordinary practice with the flap shutter. The sensation of certainty, and the absence of that "faint" feeling on a hot summer day after an interview with a strong-minded child or a group of animals, are recommendations of the reflex which need no emphasis to professional photographers.

GORDON CHASE.

## WHY I USE REFLEX CAMERAS.

[In the following article, Mr. W. Thomas, whose confessions in matters of practice concerning pictorial work are deserving of a careful attention, gives his reasons for adopting the reflex type of camera for securing negatives which are satisfactory not only as regards composition, but in the important respects of full exposure and good tone-rendering.—Eds. "B.J."]

AMONG my photographic treasures the negative from which the small illustration to these notes was made ranks certainly as one, for it represents an incident which formed the turning point in my method of working when dealing with outdoor subjects.

On the introduction of flat-field lenses it was not long before opticians began to open out the apertures of small lenses especially intended for use on hand-cameras, and among the first so to do in this country were Messrs. Dallmeyer, who, some years ago, experimented with the intention of producing lenses working at  $f/4$ , and able to cover a quarter-plate whilst giving a perfectly illuminated image with no falling away in quality or definition towards the edges of the plate. When their investigations had resulted in a work-

ing model, the late Mr. Thomas R. Dallmeyer asked me to put it to practical trial, for which purpose one of the new lenses formed part of my working kit on a sketching and photographic trip up the Yorkshire coast, where I happened to be especially concerned in obtaining a series of photographic illustrations of the herring fishery.

I had looked many times with envy at the fish sales which took place inside the covered sheds along the fish pier, and on more than one occasion had hazarded an exposure, with but little success. Movements of the people could only be caught and suggested by means of brief shutter exposures; and even the most sensitive plate, with a lens aperture of  $f/8$ , so far as my personal experience went, had proved inadequate to give fully exposed negatives.

ing fitted the new lens on a small camera, I wandered to the harbour. A number of test exposures were made working at its full opening,  $f/4$ . Then, going on the to make a few colour notes *inside* one of the sheds, some nanced to be brought in, and presently to be sold by t. It seemed a fitting opportunity to expose the last which was done. The illustration shows the result, al data being as follows:—Lens aperture,  $f/4.5$ ; plate, rial Special Rapid"; focal plane shutter, speed 1-25th of a ; developer, metol-hydroquinone.

ing allowances for loss of quality through mechanical and rapid machine printing in a newspaper, there yet should air amount of detail shown in the shaded parts of build- hich, by the way, had very dark wooden roof and walls) and modelling suggested on the dark side of each figure group; at least, if it be not so, it will be entirely the of the blockmaker or printer, for in the original negative rints the whole appears fully exposed and well graded.

### The Road to Orthochromatic Hand Camera Photography.

developing the first batch of plates exposed the results a surprise, and opened up prospects of work hitherto one had been unable successfully to with when giving shutter exposures. Especially did large lens aperture promise well in connection the use of orthochromatic plates and colour screens, mise subsequent experience has fully borne out; for now, with increased sensitiveness of colour-corrected plates, and as stained with dyes, which cut out a large proportion of ore active light rays, while allowing most of the others ss only slightly obstructed, we are able to obtain all the t of colour-plate and screen which hitherto only those stand cameras and giving exposures from one second rds enjoyed.

de-aperture lenses not only pass a flood of light to our s, but also open out a wide range of work for users and cameras; but these immense advantages are accompanied e serious trouble arising from difficulty of focussing with ent accuracy when using the ordinary distance scale. It e done—is daily done; but when a camera is employed y for purposes connected with pictorial work, it becomes, y the least, desirable to eliminate any uncertainty at the critical stage—that of arranging the scene and giving that amount of definiteness to one or more objects which necessary. This may best be done when it is possible to r the scene as a whole, and to see just how it becomes reduced u to the small size it will occupy on the sensitive plate; it is this opportunity of so doing which forms one of the ggest claims of the reflex form of camera, showing, as it (or should) a perfectly true and brilliantly lit replica in ture of the original scene or subject, allowing it to be ted, and alterations made either in placing of the sub- or altering focus from one degree of sharpness to another, atuating or repressing, and all right up to the moment of ing the exposure, with the certain knowledge that just as appeared on the screen so will it be when the plate after

exposure is developed. This, however, is only possible provided the camera is truly adjusted—if register of the image as thrown on the ground-glass screen is the same as when it is projected on to the sensitive plate or film.

Reflex cameras are not toys; they need during construction careful workmanship, and that of a skilled nature, and hence cannot be produced at so low a cost as ordinary cameras; but when they are wanted for important work, any cost they may entail, providing it be within reasonable limits, and not mere fancy extravagance of idle display or unnecessary features, is

worth paying; and however many pounds the cost of a camera may run to, an effective instrument will prove ample return. Once a really reliable camera of this style, in conjunction with a wide-aperture lens has been handled, few, I fancy will ever care to return to a more or less blind method of working and trusting to guess-work in focussing. Such has been my own experience when the reflex camera is what it pretends to be; but if it should be improperly or carelessly constructed, then woe betide the wretched owners, for failure—wholesale failure—is bound to be their portion.

W. THOMAS.

PRESENTATION.—At the annual general meeting of the Northern technic Camera Club, the students of the Photography Classes (ion 1906-07) showed their appreciation of the instruction given hem and of their teacher by presenting Mr. W. T. Wilkinson with mpanion set of pipes, pouch, and silver vesta box suitably ared.

HE "BLUE BOOK," the year book of the Scottish Photographic ection, for 1907, is to hand, with abundance of evidence as to ctivity and energy of the body it represents. The book itself enlarged by twelve pages, and, owing to the increasing number

of Associates, it has been necessary to print 3,500 copies of the pre- sent issue. Amongst other features, it contains a list of federated societies, the rules of the Federation, list of competitions, calendar of the chief photographic events of the year, a list of photographic experts in various branches of photography who will give advice to any Associate applying to them, and a gazetteer of places of photo- graphic interest in Scotland, together with the names and addresses of local reporters and dark-rooms. The book being only of waistcoat pocket size is very convenient to carry about. The secretary of the Federation is Mr. John B. MacLachlan, Blairgowrie.

## THE EXHIBITION OF REFLEX CAMERAS.

THE collection of photographs which, in the words of the catalogue, "illustrate the facilities" of reflex cameras, is obviously miscellaneous in character, and it was inevitable and desirable that it should be so if the exhibition is to carry out, as we believe it does, our intention to make it as broad as possible; in other words, to allow it to make itself, within certain limits of space and technical interest. It will be found, for example, to contain, at one end of the scale, some of Mr. Percy Lewis's beautiful and oft-medalled pictures, and at another the highly factual records of jumping horses and athletic sports. Yet both undoubtedly "illustrate the facilities" of the type of camera, some thirty examples of which are brought together. It is perfectly true that the triumph of the most perfect reflex *may* be equalled by a camera in which the focussing is by judgment, not by eye, but the accent is on the "may," and the difference lies in the percentage of occasions on which the reflex succeeds compared with that of its competitor, that is in the destruction of the handicap under which the less skilful undertake their work. Reference will be made next week to the pictorial aspect of some of the photographs, and we must now content ourselves with pointing out, more especially for the benefit of the less experienced visitor, one or two instances of photography which by the ordinary methods is difficult work, but is made easier by the adoption of the reflex principle. We refer to the same matter in the editorial on another page, but the question will bear repetition in relation to concrete examples. Objects in very rapid motion present no difficulty as regards their sharp rendering on a plate—apart from full exposure—if they are a good distance away, or if, with a very fast shutter, a moderate aperture of lens

is employed. But when they are close, or if a large aperture be used (to secure full exposure), the difficulty of securing them when they are sharply focussed increases enormously. The such photographs as "Feeder and Striker at 'Cat,'" (No. 43), "Bowling at the Nets" (No. 44), by the Rev. H. Burton, the of sporting subjects shown by the Kodak Company, or the "Tennis" of Messrs. Watson (No. 67), are of a kind which many may be exposed to get one print for exhibition, though the need not be better in one case than the other. Actually state of plate expenditure alongside prints obtained would be the first of the value of a reflex camera, and one under which we hope it would show up well.

To take an entirely different class of work, "Going Off to the Gun" (No. 26), by W. Thomas, is an enlargement from one single negative taken through a yellow screen with a shutter exposure. The rendering of the sky at the same time as of the dark red sails of the fishing boats is evidence of its method of production, the essence of which was the use of a large aperture lens on a reflex camera. The figure study, "Bother the Children" (No. 13), also by W. Thomas, is a similar instance, this time, not of the use of orthographic rendering, but of the need of the large aperture and of sharply focussing when working in dark places. Cognate difficulties will no doubt have been experienced by our readers, and a study of the methods of others, side by side with the actual apparatus itself, proves of service to the photographers desirous of making the best use of their experience and of advancing the standard of photography, one of our aims in planning the exhibition was accomplished.

### A REVIEW OF THE APPARATUS.

NOTE BY REVIEWER.—The task of describing the many different instruments collected in the exhibition is one which is rendered difficult by the very diversity of the means taken to obtain the common end, as well as by the limits of space, if the desirable course of assembling the reviews of all in one issue is to be followed. Fortunately, many of the cameras specified below were well known to me; some had been in regular and appreciated use, whilst others were seen for the first time only a day or two ago. Yet while the method of rapid review has its opportunities for error, it has also the advantage of assisting the reviewer in seizing on the points peculiar to the different instruments, the result of which is, it is hoped, apparent in the pages which follow and have, it should be stated, greatly exceeded the number originally thought sufficient for the purpose.—G. E. B.

#### Adams and Co.

OF the "Videx" of Messrs. Adams and Co. a long article might be written without exhausting the many excellent features of this widely-used instrument. Messrs. Adams have long been continuously at work upon hand-camera construction, and it is not too much to say that the "Videx" represents a degree of perfection of design beyond which it would seem impossible to go. In the "Videx" the focussing and the shutter release are placed on the right and left of the camera respectively, an arrangement which the makers put in the very forefront of reflex camera work on account of the facility which it offers for focussing a moving near object right up to the instant of exposure. We shall refer to this question in a leading article next week, but we may mention here the very great favour extended to this system by a press photographer with whom we have discussed the relative advantages of such a system, and that of focussing on a given distance, and then waiting for a figure or other moving object to come into focus. The experience of our friend was absolutely in favour of the constant focussing up to the instant of exposure, or perhaps we more correctly describe his attitude if we say that he regarded the ability to do so when necessary as an essential feature of a reflex instrument, and we know that in his case and in that of others employing the same system, the manipulation of the focussing pinion with the object of keeping the subject in sharp focus has become a matter of habit. The "Videx" is, of course, a double extension instrument, the longest extension from lens panel to plate being 11½ inches (quarter-plate). The extension bars give a very rigid support to the front. The rising and falling front is likewise actuated by rack and pinion, and works with all the ease which such a movement should have to be of real comfort in practical work. In addition to the rise and fall, the "Videx" possesses the unique feature of a swing front, which not only tilts the lens upwards or downwards, but automatically brings it back to the position of "squareness" to the

plate, the whole process dispensing with supervision by the eye of the operator, and being done by touch. The swinging panel is reversible, and may be used the other way of the plate, although the reasons for it in this latter position are not so numerous as in the former, for, as a little consideration will show, the very common instance

which a subject such as a procession or a crowd of people is being photographed from a standpoint above them—often the only one a press photographer can get—the use of the swing front will enable the photographer to bring into focus both foreground and distant even with the lens at the large aperture of  $f/4.5$ . The movement is an "extra" to the "Videx," but one which a press photographer

cular and many an amateur worker will find of the greatest use.

The lens panel is hinged so that the back of the lens is instantly visible for cleaning, and the same operation gives access to the mirror, which can thus be dusted in a few moments before commencing work. The lens, too, is well sunk into the front, a point of great importance when using anastigmats of large aperture, the access of extraneous light to which must be prevented as much as possible, or at least easy to obtain veiled negatives. The same applies to almost all lenses when working against the light. A lens hood is also provided to the same end, and is used also to cover the lens entirely. Coming to the shutter, the "Videx" has all the advantages of other cameras, of rapid adjustments and of alterations to the speed whilst the shutter is set, and the plate remains uncovered. Moreover, the shutter alone provides for time exposures instead, as is usually done, of raising the mirror of the camera for commencing the exposure after setting the shutter open, and closing by releasing the shutter. The difference is perhaps not of the greatest importance, when, as in the "Videx," the mirror rises without tremor, but it may be somewhat convenient to make time exposures altogether with the shutter.

What is to our thinking the great virtue of the "Videx" construction is the very rapid change from instantaneous to time, necessitating only the turning of the "T. and I." disc, and the setting of the blind aperture to "T.," a most convenient and workmanlike device.

The range of speeds in the quarter-plate size is from 1-8th to 1-1,000th of a second, and are all obtained by altering only the width of the aperture in the blind. This is done by simply pulling out the winding lever on the right and pressing it backwards or forwards until the desired speed mark on the dial on left comes opposite to the pointer.

A fine adjustment can be made at the instant before exposure. The mirror and the means for the examination of the image are very easily looked after in the "Videx." The former is well balanced, and its motion on release is, as we have just stated, marvellously gentle. The camera is very efficient and comfortable 8 in. in height is employed, and is fitted with self-erecting springs, and fitting very comfortably around the eyes. When out of use it folds in under hinged portion of the camera top, the handle on which affords a very convenient hold of the camera.

The "Videx" is fitted with revolving back, changing the plate, all ready for exposure, from horizontal to vertical, and vice versa, and like other movements of the camera is contrived in exceedingly compact space, and is made, for smoothness of working, of German silver.

The extension struts of every "Videx" will be found marked with numbers at which the "Adon" telephoto lens works when at this distance from the plate, this addition facilitating exposures when using this compact form of telephoto lens.

We have some lingering doubt as to whether we have not omitted to mention some minor facility of the "Videx," but we believe the provision of the small drawer (which springs open) in the base in which a light filter or other small accessory may be carried, completes the enumeration of the virtues of this modern instrument, as fully supplied, though Messrs. Adams also fit several accessories for investigation, chief among which is a mirror on the front, with which to photograph exactly at right angles to the line along which the instrument is pointed. The outside dimensions of the quarter-plate instrument are  $6\frac{1}{2} \times 7 \times 5\frac{1}{2}$ , and the price, without lens, but with three double slides, is £22.

### W. Butcher and Sons.

MESSRS. BUTCHER send a quarter-plate reflex which they style the "No. 6 Ralli," which presents one or two features out of the ordinary. The front carries a panel to which is fitted a box which, in turn, carries the lens. The panel may be placed with the box either behind or in front of it. The former arrangement recesses the lens and shields it from direct light; the latter affords an addition to

The No. 6 "Ralli."

the normal camera extension. The device, too, renders lens and mirror very accessible for cleaning.

The hood consists of an upper headpiece, supported on an upright bellows extension, and is adjustable to any height by a lazytongs strut inside it. The mirror, shutter, rotating back, and focussing

The No. 5 "Ralli."

arrangements are similar to those of other cameras, providing for the mirror being always down unless latched up, and giving instantaneous exposures up to 1-1,000th of a second, and time exposures without the mirror—i.e., with the shutter alone. The price of the camera without lens and with three slides is £8 8s.

## THE NO. 5 RALLI.

This instrument, shown in half-plate size, is similar in general arrangement to the No. 6 of the same series, the chief point of difference being that the front is fitted with a rotating lens panel, which gives a rise of front either way of the plate. This adjustment is necessary when turning the camera on its side for vertical pictures. The lazytongs hood and other accessories are the same, and the price of the camera, with three slides and without lens, is £7 7s.

## City Sale and Exchange.

THE "Planex" camera of the City Sale and Exchange is notable for its long extension, which, in the quarter-plate size, is 12in. from lens-panel to plate. The extra extension is obtained simply by pulling out the front and then using the rack, for which latter a set screw is provided. The front has also good rise and cross movement. The camera has a self-erecting hood, rising to 5½in., and is fitted with detachable reversing back. The shutter arrangement provides for a range of exposures by means of alteration in the spring-tension of the blind aperture, a convenient short table for which on the camera gives speeds from 1/10th to 1/1000th of a second. The alteration in speed is made by winding the shutter until the slit is at the top of the plate, when, on pressing in the button on the left, the aperture can be opened to the full height of the plate necessary for time exposures, and, of course, to apertures for intermediate speeds. For this latter the two separate levers on the right hand are set to "T," when pressure on the release opens the shutter and a second pressure closes it, the movements taking place without the assistance of the mirror. The tension adjustment allows of the speed of the shutter being altered immediately before exposure to the extent of one-half.

A stereoscopic form of the "Planex" is made of slightly different design as regards the shutter mechanism. The alteration in the width of the slit in this and in the half-plate pattern before us is made by winding the blind until the bottom edge of the upper blind is level with the upper edge of the inner frame of the back. The lever on

the left of the camera is then pushed to the top of its slit, and the shutter winding key can then be turned in either direction to give the width of slit shown on the indicator on the left. When the one required has been obtained the lever on the left is pushed to the bottom of the slot again, and the shutter can then be wound for exposure. The full width of the plate can be obtained and time exposures made by means of the two levers on the right of the camera. A feature of the "Planex" in both patterns is, that, unless specially locked in the up position, the mirror is always down, protecting the plate. The price of the quarter-plate "Planex," without lens, and with three slides, is 7 guineas; that of the stereoscopic "Planex," taking a plate 5½ x 3½, without lens, and with three double slides, is 9 guineas. The latter camera takes pictures suitable for postcard size.

## J. H. Dallmeyer, Limited.

UNDER the name of the "Naturalist's" camera, Messrs. Dallmeyer show a special model of the camera body made under Kershaw's

patent, which they have now adopted in place of the former design of instrument sold by them. The great feature of the camera is its long and rigid extension, fitting it for use with telephoto lens, one of which is shown in position, and will be found to bring the bar entrance of "The Old Bell" on the opposite side of Wells

Street from the "B.J." offices agreeably, if ineffectively, near. Such delicate work as telephotography the steadiest focussing is, of course, an important point, and Messrs. Dallmeyer provide an additional aid in this direction in the tightening screw which they provide for the focussing pinion, by the use of which as stiff a focussing movement as may be desired is obtained. Another convenience is a small drawer in which the focussing magnifiers, necessary when working the small apertures of the telephoto lens, may be kept. The apparatus thus provided is by no means exclusively a naturalist's camera, but a camera for various special branches of photography, where exact rigidity is of importance.

## Houghtons, Limited.

SEVERAL examples of the "Holborn" reflex cameras, made by Messrs. Houghtons, which are shown, represent a type of reflex camera with plane shutter, and are in other respects constructed on the lines

of the "Ilex" series of cameras. They have the "Ilex" magazine changer, a changing device which, as regards certainty, may be classed with the bag changer, and is superior to the latter in rapidity of action. This changer occupies the rear portion of the camera. The instruments are built to focus a horizontal picture with the mirror; an upright is focussed by scale and sighted in the finder. Mirror and shutter are set simultaneously by drawing down the

which projects from beneath the camera, and when set to "simultaneous" are both released by pressing down the lever on the right. When set to "T," the mirror may be released into the position and the shutter opened by one pressure and kept so released. The finder for vertical pictures is of the "brilliant" type. For the size of plates which they take the cameras are of small size, measuring, in quarter-plate,  $5\frac{1}{2} \times 6\frac{1}{2} \times 9$ , and they are substantially made and self-contained. The prices vary from £5 5s. to £10 10s., depending chiefly on the lens. The changer and shutter are practically identical in all, the latter giving exposures down to 1/1000 of a second.

#### Kodak, Limited.

The cameras, of quite different design, the "Auto-Graflex" and "Reflecting Premo," are shown by the Kodak Company. The "Auto-Graflex" is represented by a number of examples, claims

to be first. We may best commence by drawing attention to two characteristic features of the instrument, and then refer to the more ordinary movements. The focussing hood of the camera is shown in Fig. 1, which while it affords an unobstructed view of the ground glass, has its peculiar design in order to accommodate a mirror in the inside of the hoodboard, A. This, to allow

the camera being raised to the level of the eye and a picture taken, is often of service in cases when a view is secured over a fence, or on the many occasions of press photography. The notable features are the very quick wind, half a revolution, and the key required to set the shutter, and the easy way in which exposures are obtained, this latter and all other adjustments being made from the outside. As the shutter adjustment is rather out of the ordinary, we will briefly explain it. The shutter has five slits, the widest being the full width of the plate, the narrowest about 1/8 inch. Any one is brought into action by turning the winding key, the apertures being shown on an indicator as T (time) 1/2, 3/8, 1/4, and 1/8. The speed with a given slit is

altered by increasing or reducing the tension of the spring, the range, to take the - slit as an example, being from 1-160th to 1-25th of a second: with the 1/8 slit it is from 1-1,000th to 1-175th, so that the range is more than sufficient for the variations needed whilst doing a certain class of work. The tension alteration can, of course, be made with the shutter set and the plate ready for exposure. For time exposure the disc on the mirror lever is set to T, the shutter aperture also to T, and the mirror released to the "up" position. Pressure on the right-angled lever then commences exposure, and a second pressure ends it, the movement being very gentle and preferable in the case of most cameras to using the mirror for commencing the exposure, as with the shutter (at low tension) there is no risk of vibration, which is more than can be said of all cases of exposing by mirror, particularly when the tripod stand is not the most rigid.

Focussing and release are on opposite sides of the camera.

The "Graflex" is a single extension instrument, the quarter-plate size having an extension of 6 1/2 inches from lens-panel to plate, and external measurements of 6 1/2 by 5 1/2 by 7 inches. The back is supplied to take dark slides, roll-holders, or "Premo" film-pack, and the price, without lens, quarter-plate, is £15 12s. 6d.

#### THE "PREMO" REFLECTING CAMERA.

The "Reflecting Premo," as shown in the drawing, is fitted with an extending bellows in front, which, on its baseboard being released, emerges from the camera body and locks itself into position. The lens is brought forward in the usual manner. The camera is

fitted with an extra tall hood (9 inches to ground glass), which is firmly held by a lazy-tongs support, and instantly collapses on being pressed back into the camera. The focal-plane shutter is adjustable to ten different apertures, which are changed after the shutter has run down, by pressing the right-hand button on the camera top and turning the winding screw to the required number on the scale, and to six tensions of the spring, likewise adjusted, before or after exposure, by pressing the left-hand knob and turning the right-hand key in either direction. By suitable combinations of slit and tension exposures (as shown in the table in the lid of the camera) of 1-200th to 1-75th may be given. For time exposures a button on top of camera is turned to T, the full aperture of the blind (No. 10) is set, the mirror lowered, and the shutter wound. Pressure on the usual release then opens the shutter, and moving of the button to "T" closes it. The camera, as exhibited, also has time, bulb, and instantaneous shutter on the lens, and exposures are made with it in the ordinary way after setting the focal-plane shutter fully open. The release of the camera is on the opposite side from the focussing.

The 5 by 4 instrument measures when closed 8 by 7 1/4 by 5 inches, the extension from lens-panel to plate is 8 3/4 inches, and the price £17 15s.

**J. Lizars.**

THE "Challenge de Luxe" Reflex is shown by this Glasgow firm in the quarter-plate size, which is built to give an extension of  $10\frac{1}{2}$  inches and afford half an inch rise of front, with rack and pinion adjustment. The well recessed mounting of the lens deserves attention, and, in addition, the front of the camera is provided with a hinged panel which acts as an efficient lens shade and locks flush as protective shutter for the lens. The hood springs up, is self-erecting, to the height of  $7\frac{1}{2}$  in., and is mounted on a hinged frame, which immediately exposes the focussing screen, and on the latter being removed, gives access to the mirror. Both of these latter movements are of course of advantage in practical work, as focussing on a wet or dirty screen is an uncertain process.

The focussing screen is placed on the right, the shutter-release on the left of the camera, and the other adjustments of "T and I,"

alteration of blind aperture, and "Antinous" release are conveniently disposed. One excellent feature of the shutter is its quick wind, less than half a revolution. The alteration of slit is done with the plate covered, by winding the existing aperture to the top of the plate and then narrowing or enlarging the slit by pulling out and turning the small key on the right. The tension of the shutter spring is made adjustable to five different strengths, and the table of speeds— $1/10$  to  $1/1,000$  of a second—is conveniently placed on the camera. The instrument is fitted also with rotating back and with hooded focussing screen for direct work without the mirror. With three double slides, the price of the "Challenge de Luxe" is £12 without lens. The outside dimensions of the closed camera are  $5\frac{1}{2} \times 7\frac{1}{2} \times 7\frac{1}{2}$ .

**Marion and Co., Limited.**

THE "Soho" camera (Kershaw's patent) is one of the later models of the reflex type, and is supplied by Messrs. Marion in postcard, quarter-plate,  $5 \times 4$ , and half-plate sizes. One leading feature of the instrument is the short focus of lens which may be used with it. The quarter-plate is arranged to take a 5 or  $5\frac{1}{2}$  in. lens, and the makers tell us they have fitted as short as  $4\frac{1}{4}$  in. This is obtained by the movement which the mirror first makes on being released. It first ascends directly, and afterwards, when almost in the horizontal "up" position, makes a move forward. The reverse takes place when the mirror is put down, the mirror moving slightly backwards before descending. As a result, a rather larger lens can be accommodated than would be the case in a camera of the same size without the aid of some such device. On putting down the mirror the mechanism also raises from the bottom a cut-off piece, with which the mirror, when completely down, forms a light-tight junction shielding the plate. In the "Soho," focussing is done on the left hand, whilst the other adjustments are on the right. That for the mirror takes the form of a short rod moving in a vertical slot, A in the figure. When the rod is up the mirror is up, and vice versa. The shutter has very distinct time and instantaneous adjustments, and a quick wind which re-sets the blind in less than  $1\frac{1}{2}$  revolution of the key D. The speed indicator is on the left-hand top

corner, and gives the speeds direct. The adjustment of the lat is done (with the plate covered) by pulling out the milled screw C about  $\frac{1}{8}$  in., and turning to the required figure, the screw

having been set with the notch in it opposite to the mark on the camera. The extension of the front is very rigid on the base

struts on each side, and in the quarter-plate size gives  $10\frac{1}{2}$  in. from lens panel to plate. The camera has reversing back, square mark

Showing the Two Movements of the Swing Front.

focussing screen and hood, giving a height of 5 in. above the plate and firmly supported by a hinged metal strut.

We should mention in this connection the focussing magnifier which Messrs. Marion fit to the hood of the "Soho," and of most

reflex cameras. It consists of two paired lenses, which may be selected to suit individual eyesight on particulars being given of spectacles worn; and, in addition to permitting of very exact focusing, excludes extraneous light. The price of these magnifiers is £s. per pair.

One should draw attention, too, to the swing-front movement which is fitted to the camera at an additional cost of from £2 to £3. It gives swing movement to the lens panel, not only of the usual "looking-down" form, but also and at the same time a sideways swing like the side swing of a camera back. This latter adjustment is made simply by moving the focussing screw, while at the same time pressing in. The effect is obtained in either direction simply by misaligning the movement of one rack. The camera has also a rise of front in the quarter-plate, the outside dimensions being  $5\frac{1}{2} \times 6\frac{1}{2} \times 7\frac{1}{4}$  inches. The price in the same size with three double backs is £12.

### Newman and Guardia, Limited.

"Square-Reflector," which is the reflex camera made by Messrs. Newman and Guardia for general and tourist requirements, is characterised by the arrangement of focussing and release both close together on the right-hand side, where, also, the "time to instantaneous" movement and the mirror adjustment are made. The two-hinged level is also on this side, and is brought into a position in which it can be seen by a quick glance from the hood when the camera is watching the image on the screen. One minor but immensely convenient feature of the mirror adjustment is the fact

FIG. 1.

the position of the adjusting lever, \ or —, corresponds with the "down" or "up" position of the mirror, and this shows at a glance whether the plate is covered or not. Yet the user is not left to his eye alone, for the locking mechanism of the camera prevents the shutter being wound and the back being reversed until the mirror is up, and thus renders it impossible to expose a plate or film when, as in using a changing-box or a roll-holder, not shuttered after each exposure as it is when using dark slides.

As its name indicates, the "Square-Reflector" is built square, and rotating back, which quickly assumes the horizontal or the ver-

FIG. 2.

position, and carries with it the shutter and dark slide, changing-box, or other plate-holder in readiness for exposure. The focusing screen is distinctly marked for the "upright" and "landscape" picture.

In its normal extension the "N. and G." takes a lens of as short a focus as  $5\frac{1}{2}$  in. in a quarter-plate size, a facility which every reflex

camera does not possess. It should be mentioned that when racked home the Zeiss "Protar," or other suitable lens, is at focus for infinity. The double extension is obtained very quickly and without racking by releasing a screw below the baseboard and at once pulling out and clamping. The rising front is very conveniently actuated by the central screw seen in the drawing.

The lens usually supplied with the "N. and G." reflex is the Zeiss Protar, of  $f/6.3$  aperture, which is specially mounted for the purpose, so that the front combination is instantly removable to allow the back to be used as a lens of double the focus at  $f/12.5$ . Space is provided for the front component in the small chamber at the side shown in Fig. 3, and we can say that the operations of extending the front and removing the front lens are the work of not many seconds, and may be done whilst the worker has his eyes on the subject for which he is making the change. The complete lens is removed by pressing the two small handles in the special mount. The two separate components may then be replaced in the original mount and used on another camera if necessary.

Mention has already been made of the block system by which the shutter is prevented from being re-wound until the mirror has been turned down, but it should be added that the shutter works at a constant tension of spring, and obtains the range of speeds (1-10 to 1-800 of a second) in the quarter-plate by reducing the width of the slit, the 1-10 speed being the full aperture of plate. This adjustment of speed may be made when shutter is set, and

FIG. 3.

up to the moment of exposure—the speed scale is in quite the most convenient position for viewing in the case of a vertical picture, and almost equally so for horizontal pictures—and Messrs. Newman and Guardia's reputation for the accurate marking of the speeds is one which is universally acknowledged. The "N. and G." hood differs from that of most patterns in being erected on aluminium supports, which spring into position on the hood being pulled up. The hood can be lifted out of its clips at the base and the ground glass cleaned, and the latter can also be removed to dust the mirror. For critical focussing a binocular eye-piece is supplied.

The camera back is built open, and thus allows of the use of film pack, dark slides, changing-boxes, and other exposing apparatus, for several of which a specially registered carrier is supplied.

The large rise of front—one inch—and its comfortable adjustment by the milled screw seen on the front in Fig. 2 are two excellent features of the "N. and G.," as are also the recessed position of the lens and the lens shade, which also acts as a cover or cap for time exposures. When closed, the measurements of the camera are  $6 \times 6\frac{1}{2} \times 6\frac{1}{2}$ , and the instrument is free from projecting parts which may be accidentally damaged. The thorough workmanship of the instrument is of a kind on which the makers justly pride themselves. The price of the camera without lens and with three slides is £27 10s.

### Ross, Limited.

THE reflex principle in a different form is embodied in the two cameras shown by Messrs. Ross, Ltd., in which two lenses are used, one for focussing and one for exposure, the image from the upper one being cast, by means of the mirror, on a horizontal focussing screen. This adaptation amounts to the old twin-lens camera deprived of the inconvenience of examining an inverted vertical picture. In the quarter-plate camera shown the lower of the two "Homocentrics" is fitted with the Koilos shutter, the  $5 \times 4$  having an Ernemann focal-plane. In other respects the two cameras are identical. Both have rise of front with rack adjustment, in both the top of the camera is hinged and is released by two catches in the front, and thus permits of the mirror and ground glass being readily adjusted. Both have a turn-

table back, to use which the hinged piece at the back of the camera is released by the button on the right, when space is afforded for the rotation of the back. The hood is of ample dimensions, and rises seven

inches above the ground glass. The cameras are covered in hard black leather of practically everlasting wear, and are most substantially made in other respects. The size of the quarter-plate when closed is

$5\frac{1}{2} \times 6 \times 9$ , and the prices complete, with two Homocentric lenses,  $f/6.3$ , and three dark slides, £17-18s. In the  $5 \times 4$  the dimensions are  $6\frac{1}{2} \times 7 \times 10$  in., and the price, with lenses and slides as before, £24 12s. A smaller and less expensive pattern of the twin-lens reflex is made without the reversing back. It is in other respects similar to the two patterns shown.

#### Sanders and Crowhurst.

THE "Birdland" camera, an example of which is not in the exhibition at the moment of going to press, but which it is anticipated will be on view when the collection is opened, is an instrument of a particularly wide range of movements, and is manufactured specially for the more serious branches of photography, not solely for naturalistic work, although that is the primary object of its design. The  $5 \times 4$  size, which we are now reviewing, has a normal extension of  $8\frac{1}{2}$  to 9 inches from lens-panel to plate, but the distinguishing feature of the apparatus is the very great extension

obtainable with it. The front board of the camera pulls down and locks to form a baseboard, on which an extra extension of six inches is at once obtained by pulling it. A subsequent use of the rack brings the total extension to no less than 22 inches from lens-board to plate. In this  $5 \times 4$  size the camera has a rise of front fixed by a set screw, and, when fully extended, is remarkably rigid. The shutter is a Goerz model "A," which provides for instantaneous exposures up to  $1/1,000$ th of a second, bulb automatic exposure from

$\frac{1}{4}$  to 5 seconds, and also time exposures. One good feature of the shutter is its remarkably quick wind, only about one quarter of revolution. The shutter-blind is of the two-aperture pattern, but higher speeds being obtained by increasing the tension of the spring. The change from time to instantaneous exposures is thus very conveniently made. A focussing lever is placed on each side of the camera. As regards the hood, the makers adopt a two-fold system first, the ordinary one in which the ground glass screen is examined from the aperture of the hood vertically above it; and, secondly, by means of a second form of hood with which the camera can be held at the eye-level, and an inverted image seen in a mirror fixed in the front of the hood. This second system is brought to a still further

degree of perfection by means of a different pattern of hood, which forms a solid prism-shaped erection over the ground glass and carries a telescopic focussing eye-piece. This latter accessory is specially serviceable for telephoto work, as it permits of the most accurate focussing even at a comparatively small aperture. In respect of construction, the camera is throughout of very substantial build and while its cover of green leather particularly fits it for the purposes of the naturalist-photographer, appearance is not in any way sacrificed. The price of the camera without a lens in the  $5 \times 4$  size is £25; quarter-plate £20 17s., in each case with three slides.

For use with the camera the makers supply a specially short tripod giving a position of only about 2 feet from the ground, and supplied with a top measuring  $7 \times 8$  inches in the form of a tilting table, by which the camera can be firmly pointed at any angle, or may even be directed vertically upwards or downwards.

#### Spiers and Pond, Limited.

THE new "Specto" reflex of this firm is not to hand at the time of going to press, but it will doubtless be among the exhibits when the exhibition opens, and we shall notice it in due course.

#### O. Sichel & Co.

A SMALL reflex taking the now popular size of plate of  $2\frac{1}{2}$  in.  $\times$   $3\frac{1}{2}$  in. is shown by Messrs. Sichel. It carries a focal-plane shutter giving

time and instantaneous exposures, and has the good feature that the mirror automatically returns to the "down" position unless specially

sh to remain up. The focussing is provided by the lens which supplied in a mount of this description. It costs, with a  $4\frac{1}{2}$  in. anastigmat ( $f/6.8$ ), £7 7s., or without lens £4 5s. These prices include six single metal slides. The camera is a very compact one, appears to us to be strongly made. It is sold also in a superior form with reversing back.

#### A. E. Staley and Co.

The "Royal Reflex" long extension camera is shown by this firm, presents several distinct features. The mirror lever acts also as the shutter release, and does not of itself lock the mirror in the "up" position. The mirror is thus always down unless released "up." For this, the small locking knob immediately behind the release bolt must be moved, but the auxiliary movement may be made almost simultaneously with the first. The shutter is provided with adjustable slit and tension, both of which movements may be made while the shutter is set and the plate waiting exposure. That of the slit is done by pressure on the grooved knob on the left of the camera, and turning the knob on the right-hand side until the required aperture (1 to 8 millimetres) is indicated in the opening. A separate "T" aperture of slit is provided in the same way for time exposures. The tension is adjusted in the usual way, and the two movements together are

safeguards the plate during rewinding. The focal-plane shutter is adjusted as to width of slit and tension in the same way, and the time exposures are given with it. The camera extends to  $7\frac{1}{2}$  inches from lens-panel to plate, and will take a lens

of as short a focus as  $4\frac{1}{2}$  inches. It has rotating back, rising and cross front, and collapsible hood 5 to  $6\frac{1}{2}$  inches from the ground glass. It is sold, with 6 single light metal dark slides, at £7 7s.

#### Talbot and Famer.

MODEL C is shown of this firm's series of reflex cameras, the London agents of which are Messrs. Taylor, Taylor, and Hobson. This model is not of the focal plane pattern, but provides for exposures up to 1-100th of a second. The mirror is set by pulling down the cord emerging from the bottom of the camera, this same operation also setting the shutter. The speeds are altered by increasing the tension of the shutter spring, just as in a Thornton-Pickard roller-blind shutter, and are marked for 1/10, 1/20, 1/40, 1/60, 1/80, and 1/100. For time exposures the shutter and mirror are set in the ordinary way, the small stud on the right is then pulled out and the release pressed to raise the mirror. The exposure is ended by pressing the small stud. The camera is fitted with a sliding reversing back for vertical and horizontal pictures, the back being made separate and square, so that it may be used either way of the plate.

A rise of 1 inch of the lens is provided with very convenient rack adjustment at the base of the camera on the right. Release and focussing are on opposite sides, and the hood,  $5\frac{1}{2}$  inches in height, has a very strong hinged strut. When closed, the camera measures  $5 \times 7\frac{1}{2} \times 6\frac{1}{2}$  inches, and costs, with three double slides, but without a lens, £5 15s. It is fitted also with focussing screen for direct work on a tripod.

#### Taylor, Taylor, and Hobson, Limited.

to obtain the speeds tabulated on the side of the camera from 1-1,000th to 1-6th of a second.

Time exposures are given without the aid of the mirror, by turning the slit to "T," setting knob No. 4 also to "T," and locking the mirror in the "up" position. The knob No. 7 is then pulled back to open shutter, and again pulled to close a series of exposures, which are made in less time than it takes to describe them, and dispense with the mirror.

The hood is built square, and, in the  $5 \times 4$  size, is  $5$  to  $7\frac{1}{2}$  inches from the ground glass. The camera has a double extension, the length from lens-panel to plate in the  $5$  by  $4$  size being 5 inches. The extra length is obtained by pulling out two small bolts, pulling forward the front, and again locking with the front. The back has a rotating turntable, and rising, falling, and front movements are also provided. The total dimensions of the  $5$  by  $4$  camera when closed are  $6\frac{1}{2}$  by  $6$  by  $7\frac{1}{2}$  inches, and the camera without lens, but with three double slides, £8 8s. In quarter-size the price is £7 7s.

#### THE MITE DE LUXE.

This reflex camera for a  $3\frac{1}{4}$  by  $2\frac{1}{2}$  plate is in many respects similar to the foregoing. The mirror, however, is arranged to catch in the "down" position, its lever, which is also the shutter release, being to be depressed to obtain it in the "up" position. It thus

The well-known firm of "Cooke" lenses, in its contribution to the exhibition, shows the first actual evidence of its entrance into camera manufacture, a branch of work which, as we have long known, it has been their intention to undertake sooner or later. The camera, which at the moment has not been christened, is designed for use with a "Cooke" focussing lens in which, as our readers should know, focussing of nearer objects is done not by moving the lens from the plate, but by shortening the focal length by a slight movement of the negative component of the lens. The use of a lens of this type thus dispenses with one necessary movement in the camera, and the lens is so mounted that it can be used in another camera. Messrs. Taylor take a short cut to portability by omitting the reversing back and building the camera to take the picture the landscape way of the plate, and in regard to lightness, the use of aluminium, vulcanite, and thin wood, is applied to reduce weight consistent with the retention of strength, with the result that the weight, complete with focussing screen, is 2lb. 12oz. in the quarter-size.

As regards the manipulation of the camera, the makers arrange all the adjustments to be performed by the right hand, whilst the camera

is grasped by means of the carrying strap on the left. The instrument is fitted with a locking device, which prevents the plate or film from being accidentally uncovered, an adjustment which is applicable to reflex cameras with peculiar ease, and finally the outside is commendably free from projections, the total outside dimensions being  $6\frac{1}{2} \times 5\frac{1}{2} \times 4\frac{1}{2}$  inches.

The camera has rising front, each way one quarter the height of the plate, that in the vertical direction being geared to the finder, and tilting its lens, as the front rises, so as to show the exact view on the plate. The focal plane shutter is of the single-slit type, and allows of the width of the slit being increased or reduced after the shutter is set. The setting mechanism works very silently, and time, bulb and instantaneous exposures—the latter within the range of 1-10th to 1-800th of a second—can be given. The shutter, as already stated, cannot be set whilst the mirror is up.

In using the shutter, the winding key is pulled out and turned backwards and forwards until the required actual speed is seen in the recessed aperture just above the key. The "hand" exposures, as Messrs. Taylor term the usual "bulb" exposures, are made by setting the lever above the winding key to H, setting the blind aperture to 1/10, and winding the shutter one revolution only, that is to leave the plate uncovered by the blind. Pressure on the release then raises the mirror and commences the exposure, and the plate remains exposed until pressure is withdrawn.

For time exposures, the lever is set to T, a smart decided pressure on to the release then raises the mirror, and exposure continues until the lever is moved from T to H. All three forms of exposure may be made by the Taylor-Bowden release, or by pneumatic bulb having a similar fitting.

To the hood, which is of light metal, an adjustable stereoscopic eyepiece is provided, its distance from the ground glass being  $4\frac{1}{2}$  inches. The back of the camera is built open so as to admit dark slides, changing-box, film pack, Mackenzie-Wishart slides, or indeed any of the usual plate or film-holders. Mention should also be made of the convenient fitting for holding single metal dark slides. Pressure on a bow spring releases the slide or permits of its insertion. A similar quick lever secures the ground screen which is fitted for focussing direct, a useful provision when using the camera on a tripod.

### Vogtlander and Son.

The standard reflex camera of this old-established optical house, represented in this country by Mr. F. G. Phillips, of Charterhouse Street, E.C., is quite distinct in construction and manipulation. The hood is square pattern ( $4\frac{1}{2}$  in. each way), and is erected by hinged spring struts inside it, which maintain a clear view of the focussing screen at eight to nine inches. The board carrying the hood is hinged and turns back, exposing the focussing screen, which in turn

is instantly removable, giving access to the mirror for dusting, etc. The extension in the quarter-plate size is 10 $\frac{1}{2}$  in. from lens panel to plate, and the distance from the mirror (at the most forward point in its course) to the inside front of the camera is four inches, distances which will give an idea of the focal lengths of lens which may be used. Usually, the camera is supplied with a Heliar of  $f/4.5$  of 7 $\frac{1}{2}$  in. focus.

The front has both a rise and fall of nearly one inch, and contains a removable panel for the lens, which in the quarter-plate size is under review is mounted in a short extending tube to avoid contact with the mirror in certain positions. In the case of the half-plate camera this is not necessary.

The focussing and shutter release are placed on opposite sides of the camera (on the left), the pinion for the former being provided with a set screw on the right. The lever for getting the mirror also placed on the left, whilst the remaining adjustments of width of slit and tension of shutter are on the right. The selection of blade aperture and tension spring are designed to give a range of speeds from 1-12 to 1-1,000th of a second, in addition to which there is provided a brake for the spring tension (to be used with caution) giving a still slower shutter exposure.

A good feature of the shutter is the fact that it gives time exposures without the aid of the mirror. The blind aperture having been set to full width of the plate, pressure on the release opens the shutter, and a second pressure closes it. Mention should be made of the reversing back of the camera and of the telephoto attachment fixed focus giving a magnification of  $2\frac{1}{2}$  times, i.e., with an equivalent focal length of 18 inches.

### THE VOIGTLANDER BIJOU REFLEX.

One of the novelties of the exhibition is a tiny reflex camera, the only example in England, of a new reflex camera taking a plate about  $2\frac{1}{2} \times 1\frac{1}{2}$  inches. A set of the prints, and some enlargements therefrom from these small negatives will be seen on the walls, and testify to the fine definition of the lens and the exact focus obtained, a task not so difficult with a short lens as with one of longer focus. Although measuring only  $3\frac{1}{2} \times 4 \times 4$ , the camera has yet the adjustments of its larger prototype, including a reversing back and focal-plane shutter. This latter is provided with two slits, both of which may be used for rapid shutter exposures, whilst the wide full width of the plate, serves for time exposures. Alteration of the speeds by increase in the tension of the spring is also provided. The camera is fitted with a changing box carrying a dozen plates, and accommodates, if necessary, a focussing screen for direct horizontal use.

A telephoto negative lens screws into the flange on the camera front, and the Heliar lens being screwed into its other end, a telephoto system is produced of sufficient rapidity for snapshot work, and places subjects within the grasp of the user of such a small camera which would be impossible without such aid.

### W. Watson and Sons.

THE "Argus" camera, which Messrs. Watson show in the half-plate size, is made in two patterns, horizontal and square, the latter having a reversing back placing the plate also in the vertical position.

The camera is of the double extension type, permitting in all sizes of the use of the single component of the "Holo-stigmat" lens with which it is fitted. The makers take advantage of the optical fact which they point out in the "Argus" prospectus, that a single anastigmatic lens placed in front of the diaphragm requires a camera extension which is shorter to a notable degree than that required by the same component used behind the diaphragm, like an ordinary landscape lens, but the size of the image is practically the same in either case. This curious behaviour of thick meniscus lenses, the point out, is due to the contraction of the cones of light within the lens in the first case, and a corresponding expansion of the cones of light within the lens in the second case, which causes the cardinal planes both to lie entirely outside the lens beyond the convex side. The extra extension of the "Argus" is obtained by simply pulling out the front; the rack and pinion is used in the usual way for focussing. A rising and falling front is provided, which normally is one inch each way in the half-plate size, though the construction of the front allows of more in one direction being obtained at the expense of the other.

The focal-plane shutter has adjustments, both of tension and speed, which together give the range of exposures, tabulated on the side of the instrument from 1/25 to 1/800 in the camera shown. The alteration of slit is made, with the plate covered, by turning the winding key till the two arrow marks coincide, the upper pinion traversing

back of the camera is then pushed in on the left, and the head on the right turned until the required width of slit is indicated on the left. Slits of 2, 5, 10, 20, 30, 40, and 50 millimetres are provided, as also one the full width of the plate for time exposures. The tension adjustment is made in the usual way by the pinion passing through the lower portion of the camera. It allows of the head being altered—to the extent of  $\frac{2}{3}$ , the time with the lowest tension—immediately before exposure.

The working of the shutter and mirror is done in conjunction with the lever marked E in the drawing. The mirror, unless latched the "up" position, is always "down," the lever E being then the top of the slot, as in the drawing. On now turning

winding key—which, by the way, sets the shutter in one and a half revolutions—and setting the other adjustments to "I," the camera is ready for instantaneous exposures. It is released by pressing on E, which raises the mirror and releases the shutter. Finally, after the shutter is released, the mirror falls again and shields the plate. As, without needing attention, plate after plate in a changing box or film, a roll holder may be exposed, inserting a shutter every time the shutter is re-wound. The feature is a point in favour of the camera for press or other hurried work, in contradistinction from cameras where the shutter can be re-wound, while the mirror remains down after an exposure.

For time exposures the full "T" width of slit is first obtained, the two other levers set to "T." The shutter is then wound the release pressed down. The mirror is thereby raised and locked in the "up" position, and the shutter opened; a second pressure on the release closes the shutter. In order to get the mirror more into the position for focussing, the front "T" lever is moved to "I," when the mirror is unlatched and falls. These series of movements, though lengthy to describe, are very quickly made, the mechanism impresses us as very strong and capable of standing a good deal of hard usage.

The half-plate size is fitted with a  $\frac{9}{16}$  in. hood, has ground glass screen for horizontal direct focussing if occasion requires, and measures  $8\frac{1}{2} \times 7 \times 8$  inches. Its price, with three slides and a lens, is £12; or with  $\frac{8}{16}$  in. "Holostigmat," f/6.1, £21 2s. 6d. Watson's list, obtainable at the exhibition, should be consulted for the full list of prices.

#### THE "VANNECK" CAMERA.

The older pattern of reflex camera still supplied by Messrs. Watson, and, in fact, one of the oldest cameras on the market, is shown in the drawing, which is a box form of hand camera, arranged to focus the mirror for horizontal pictures, and by scale with a finder for vertical. It provides for three speeds, includes a bag-changer magazine, and measures, in the quarter-plate size,  $4\frac{3}{4} \times 8\frac{1}{2} \times 6$ . It allows of time and shutter exposures.

#### Chas. Zimmermann and Co.

Another camera which is shown for the first time in this country is the "Ernemann" of Messrs. Chas. Zimmermann, possessing a very complete range of movements, and fitted with the already well-known "Ernemann" focal plane shutter. The front is a special feature of the camera on account of its large lens-shade— $4\frac{1}{2} \times 4$  inches—and a great rise, close on  $1\frac{1}{2}$  inches. The latter movement is made by rack and pinion adjustment, the screw of which rises in one quarter inch from its working position. The lens-shade is removable to give access to the mirror. The hood is attached to the top board of the camera, which supports it in the front and by its provision of a carrying handle gives a convenient

hold of the instrument. It is of convenient height (7 inches). Close in front of it, on the camera top, is placed a circular spirit level in a convenient place for observation. The camera is made square, with rotating back, and is adapted to work with dark slides or with the Ernemann changing-box.

The shutter adjustments are those of tension and slit, familiar already on other patterns of the Ernemann camera. They provide for exposures rising from  $1/25$  to the most rapid. Time exposures are given without the use of the mirror, a separate release being provided on the right-hand side of the camera, while that for instantaneous exposures is on the left, on the opposite side from the focussing pinion. Closed, the camera measures  $6 \times 6\frac{3}{4} \times 7$  inches; its price in quarter-plate size being £16 with "Ernemann" anastigmat. Mention should be made of the very neat and effective hood for the vertical focussing screen.

## Exhibitions.

### M. ROBERT DEMACHY'S OIL PRINTS AT THE ROYAL PHOTOGRAPHIC SOCIETY.

M. DEMACHY, having written with all the force and fervour that his graceful style allows, has now followed up his words by deeds: having, on several occasions, made his manifesto as to the incompatibility of "art" and "feeling" in uncontrolled photography, he now invites the world to a collection of over fifty prints in the oil method, saying, as it were, "Is it not all just as I said?"

This important exhibition opened at the rooms of the Royal Photographic Society on June 12, and will be free to the public between the hours of 11 a.m. and 5 p.m. until the closing day, July 27.

It is not in the least doubtful that these pictures will be generally voted artistic, though it must not be forgotten that the term means different things to different people. If we are not mistaken, it very narrowly escapes being a term of opprobrium for some critics. Artistic, at any rate, M. Demachy's prints decidedly are. And in our definition of the term, that would mean that we find them the work of a man sensitive, almost hypersensitive, to every influence that would endue them with a touch of the poetic, the romantic, the precious, and the sensuous. M. Demachy, indeed, seems not to care a jot for a picture that cannot make an appeal to minds open to such influences, and we think that herein lies his great difference from the generality of other workers, also artistic, in whose minds fancy does not breed so readily as logic. He openly avers that these pictures are not photographs; a very wise position to take, as we think, for it disarms paltry and unprofitable criticism. They are merely pictures; fancies, perhaps, would be a truer name, since there are few having the completeness demanded by what is understood as a picture.

Taking them then for what they are, and for what M. Demachy does but claim them to be, we unhesitatingly pronounce them to be extremely delightful excursions into the domain of art. Were they but independent of a photographic basis, M. Demachy might rank as a man of note in that domain. But although he shakes himself as free as he can from this, their birthright, he cannot do so entirely. Their roots hold firm in photographic soil, and give them more sustenance than perhaps M. Demachy himself might, with pride, admit. To cut them free of the debasing commonplaces of the camera would not only rob them of their roots, but to skip from vegetable to animal, of their present backbone into the bargain. The farther M. Demachy disentangles himself the more he risks. Using another metaphor, we might say that, with the life-line of photography, M. Demachy floats admirably, and could he but swim upon the waters of art, he would, of course, no more bother himself with that line than does any other artist who paints, etches, or draws independently of any adventitious aid. For our own part we ardently advise M. Demachy to try. There is such abundant evidence of power in his manipulation of pigment, in his appreciation of "quality," and his charm of lighting, that it is hard to believe that a more direct process, like drawing in charcoal or painting in monotone, should not bring him good results after a short course in draughtsmanship, if that should really be needed.

For the present, however, he takes what he wants of a theme

photographically arrived at, and plays variations upon it as a master in music takes some humble folk-tune and uses it merely as a stimulus to his own musical thought and feeling. No one can deny the pure legitimacy of such a course when the results are not put forward with wrongful claims. The only difference between Bach and Demachy is that the immortal "Variations" do not owe their beauty to anything but Bach's own feelings, he having been quite man enough to write the theme as well, if he had chosen; whilst in the other case the theme is a *sine quâ non* which must be imported. Hence M. Demachy's pictures are exhibited in Russell Square, not in Bond Street, and all the small fry of photography may claim his reception and not be entirely beyond their rights in passing judgment from their own point of view. M. Demachy opens his door to adopt the photographic theme, and in rush all the photographers at the same time, and there is no help for it.

The state of affairs has not improved when M. Demachy hangs a "straight" print cheek by jowl with his variations, for the photographers naturally will seize upon that as constituting their opportunity. "Now," they will say, "here is a girl's head with dark hair of a heavy silky quality that is proper to hair, and has its own sensuous charm, too. Her face is pale by contrast, with modelling delicate and refined: a face that has a distinctive effect by being broadly and largely treated without accentuation of the separate features, contrasting as a whole with the dark hair that frames it in. This effect is truthful, and, to most of us, beautiful. How far has your variation outstripped it in beauty? You have first of all changed the heavy silky texture of the hair, which to us seems to be romantic and dignified, and have given it a light coloured, fluffy appearance, which we associate with barmaids and ladies 'of no visible means of support.' (We do not deny romance and dignity to such ladies, but the association of ideas is against them.) Next, you have put a lot of forcible modelling and shadow into the features, so that, in the matter of contrast, the face and the hair have transposed their effects. You have centralised the dark and reduced the hair to nothing more than a substance easily lending itself to vignetting. If it is hair, it is without character of its own, and of a tow-like texture that is a further remove from beauty rather than an approach to it. Where has your control 'come in' with advantage, in this case, at any rate?"

M. Demachy would, of course, answer that these matters are entirely questions of taste which cannot be discussed, because of a want of commonality of premises. "What I like, you don't." In all probability this essay has been hung to show the enormous scope of control which the oil process admits. M. Demachy would not maintain that, in principle, dark surrounded by light is any more beautiful than light surrounded by dark. As an example of such inversion of tones the print is remarkable.

In another case where comparison is invited between a bromide and an oil print—a street scene—the "straight" print is by no means a fine thing in itself. It is due to an exposure when the effect was particularly flat and unpromising. Another attempt might have resulted in a fine effect of light and shade, and this no doubt more convincing than M. Demachy's oil print of the same print, which has an abundance of effect, but less of plausibility. Its scheme of light and shade is not explained in a title. Sunlight it is certainly not; moonlight it may be; but a hidden arc light seems to us the only hypothesis that would satisfy one who had made a loving study of street effects. We do not deny that it has feeling and charm, which the bromide print entirely lacks; but M. Demachy, who has faith in his process sufficient to remove lamp-posts, has made a *fantaisie* of it. *Fantaisies*, such as his No. 2, may be delightfully fairy things in figure work, but somehow in a street of houses the fantastic seems most fit and proper when confined to the architecture.

"Sourire," "Etude de Geste," "L'Orient," "La Curieuse," are all specimens of this *fantaisie*, this light, almost inconsequent touch, which lifts the work of M. Demachy far into a higher region of achievements. They are quite delightful, because they admit, in their subject and the manner of approach to their subject, a light, unworldliness, best understood to an Englishman by the term "French" (not "frenchy"! ) In such exercises of art, purely for art's sake, we are not troubled, because a lady's garments end in smoke. It does not much matter that we cannot quite trace out the whereabouts of an arm or a knee. These charming pictures are trifles at the best, but a best that few of us can produce, and fewer still

would be without. They are in the realm of *fantaisie*, and as such no obligations, tonal, structural, or optical are insisted upon. Control! Yes, as much as the talented author likes to give us in this department of art. We are in his hands, and they are hands we can trust.

But if we step on to the solid ground of nature, to which alone "trusts the mind that builds for aye," are we satisfied that, all other things being equal, this magic touch that sets us dreaming of things we do not see when awake, is good for us all round, and in every case? Are purely photographic results so hopelessly devoid of truth and charm that the touch of a brush can at any time better them? The beauty of the play of light amongst houses is due to the working of inexorable natural laws. If we love the effect of that play of light, do we act wisely in not striving to preserve them as they are, or as we can catch them by photographic means? In landscape, the effects of natural phenomena are just as distinctly beyond our making. We may try to create them in the studio for ourselves; but we cannot do so at all unless we know them by heart first, and knowing them by heart means years of sharp-eye watching and slavish copying. We have no knowledge of M. Demachy's past history; he may have gone through this mill; but unless he has done so, it is doubtful whether he will ever succeed in improving even a poor photograph of a really fine effect by "controlling"—that is to say, intensifying here, lightening there, and so on, with incentives other than those which would jealously preserve the record of the effect.

And this is the point where we think he leaves us, taking his own road. His undoubtedly sensitive and artistic nature is most influenced by qualities of tone, design, idea, richness or lightness of the result and all those considerations than it is by the sensitivity of the realist who is set afire by such simple things as cloud shadows racing over downs, or the vibrating atmosphere over sunnycornfields. Both kinds of sensitiveness are artistic; but the one we take to the controlling processes and the other to the "straight" print, provided it comes of the best and most skilful photography; and abjures printed-in skies and other abominations that are the laughing-stock of those who can detect them.

It is ridiculous to compare these two artistic natures, still worse to decri one at the expense of the other. They are both valuable to the world, and each the complement of the other.

On Tuesday night the exhibition was formally opened, and a sheet of paper, written by M. Demachy, to introduce his pictures, was read by the president and highly appreciated by the audience, who all listened with marked interest to the article recently contributed "Camera Work" by M. Demachy.

Listening to these readings, we were struck with a thought which seems to put a new complexion upon the claims advanced for the oil process. It is affirmed that the tonal values of pure photography are usually wrong, and may be more readily adjusted by oil painting than by any other method. The question arises, What is meant exactly by "wrong"? "From an artistic point of view," adds M. Demachy, which leads us to suppose that his need for adjustment is after all only the need to alter the scheme of dark and light in a print, prompted by his individual feeling; it is not perhaps that he attempts by alteration to come nearer to a truthful record of the tonal values of nature than the best photography could give him. If, then, his need of control arises from this perfectly gratuitous but artistic desire to readjust the values, the question is not one of falsity of tone values at all, it is simply a question of chiaroscuro in its larger connotation, which includes all the balance of light and dark in a picture, not only that due to shadows.

---

"LA REVUE SUISSE DE PHOTOGRAPHIE" in the current number announces its decease, because it cannot obtain sufficient new matter every month to fill its pages.

"BRITISH BIRDS" is the title of a new illustrated monthly published by Witherby and Co., of 326, High Holborn, W.C., which is to be devoted entirely to the study of birds of this country. No. for June, contains articles by such well-known ornithologists as Howard Saunders, P. H. Bahr, P. L. Slator, F. C. Selous, and J. H. Gurney; whilst others of equal note have promised contributions for future issues. The price of the magazine is one shilling per month, or 10s. 6d. per annum, post free.

## Patent News.

The following applications for patents were made between May 27 June 1:—

**DEVELOPMENT.**—No. 12,249. Improvements in developing and fixing apparatus. Arthur Clarence Hayden, Norfolk House, Norfolk Street, London.

**PHOTOGRAPHIC PROCESSES.**—No. 12,304. Improvements in photographic processes. Henry Solomon Wellcome, Arthur Gerald Bates, and Frank Clement Starnes, Snow Hill Buildings, London.

**PRINTING FRAMES.**—No. 12,424. Improvements in photographic printing frames. John Batty, Carlton Buildings, Paradise Street, Birmingham.

**SLIDER HOLDERS.**—No. 12,459. Improvement in colour-screen, or filter-holders for use with photographic cameras. Edgar Samuel Hunter, 88, Chancery Lane, London.

**STANDS.**—No. 12,481. Improvements relating to camera stands. Edmund Healiss Harrison, 165, Queen Victoria Street, London.

**OPTICAL PURPOSES.**—No. 12,662. Improved camera for photographic and optical purposes. Alchanan Cohen, 53, Chancery Lane, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

The specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**PACKS.**—No. 11,033, 1906. The invention consists essentially in the combination in a sensitised film of this type having film and tab in one, of an anti-curling coating or back and of an opaque medium to prevent the passage of light, either with or without any other coating or layer of material of service for photographing under different conditions. John Edward Thornton, Altrincham, Chester.

**TRIMMING PRINTS.**—No. 11,846, 1906. The invention relates to substitutes for the trimming shapes used for photographic prints. The inventor provides for this purpose a sheet of celluloid, gelatine, glass, or other transparent material having marked thereon a number of geometrical figures—e.g. rectangles, circles, or ovals of different sizes. In addition to these figures marked on the transparent sheet, the sheet is perforated with pin-holes arranged along the lines forming the rectangles at or near the corners of the rectangles, and in the case of circular and oval figures at suitable distances apart on the circular and oval lines forming the figures.

Fig. 1 represents a transparent sheet marked with a series of rectangles of sizes proportionate to the standard sizes of photographic plates, and having perforations at and near the corners.

Fig. 1.

Fig. 2 represents a transparent sheet marked with two series of parallel lines extending for the most part across the plate, one series being at right angles to the other, thus dividing the plate into a series of rectangles. At each intersection of two lines is a perforation.

The device is used as follows:—The transparent sheet is laid the face of the photograph or picture and the lines thereon are used in making the selection of the portion of the picture desired

both as regards size and position. Then by a pin or pointer passed through the perforations *a* in the sheet at the corners of the rectangle, or around the circle or oval, selected, marks are pricked out on the photograph or picture, after which the

Fig. 2.

transparent sheet is removed and the picture can then be cut out, using the pin-pricks as a guide. One advantage of this arrangement is that the pin-pricks pass through the picture and show at the back thereof, where they can be seen more easily than at the front, and can be used for ruling or marking the outlines of the picture. By this means the face of the picture does not require to be marked. The picture can be trimmed, using a narrow metal rule, which is more convenient than glass, as it is not as liable to slip. Frederick Colin, Viscount, Maitland, Lieutenant-Colonel, Royal Body Guard, 14, Lower Sloane Street, London, S.W.

## Dew Apparatus, &c.

The Airolestyle (Air-brush). Made by the Airolestyle Syndicate, Limited, 35, St. Bride Street, London, E.C.

We have had submitted to us by the Airolestyle Syndicate, Limited, a new form of air-brush, for which many advantages are claimed over the older forms, especially in the matter of durability and simplicity. One important feature of the "Airolestyle" is the shape and position of the needle, which allow the latter being easily removed for cleaning and dropped back into its place at once. Moreover,

Fig. 1.—"Airolestyle" Ready for Use.

should the point of the needle by any chance become damaged, a new point (two extra being furnished with each instrument) may at once be screwed in in place of the old one.

The valve has but one movement, being simply drawn backward to a greater or lesser degree, according to the amount of colour it may be necessary to pass through. The working is in this respect somewhat similar to the old form; one has only to forget the pulling-down movement to admit the air, the construction of the valve obviating the necessity for this.

Two other points are worth mentioning. The first is that, as the needle works outside the handpiece, there is no opening in the reservoir; thus obviating the risk of colour flowing back into the mechanism. Also, no washers are needed in the adjustment of the cap, a feature which bears out the character of the whole apparatus

for getting all the facilities of air-brush work in the simplest possible way.

The reliability of the brush and the smoothness with which it works are beyond criticism, and undoubtedly the workmanship and finish are of the highest excellence, the adjustment of every part

Fig. 2.—“Airostyle” Showing Needle Withdrawn for Cleaning Purposes.

being as perfect as the mechanism of a gun. The firm have every reason to be proud of their success, a great many airostyles being at present in use in the Potteries and other industrial centres, meeting everywhere with the highest approval. The price we understand to be four guineas.

## New Materials.

“Autotype Spirit Sensitising Solution for Carbon Tissues.” Prepared by the Autotype Company, 74, New Oxford Street, London, W.C.

THE Autotype Company, who are introducing a new sensitising medium for carbon tissue under the name of “Spirit-sensitiser,” have been good enough to send us a bottle for trial. Before saying anything about the advantages of the new preparation we may appropriately refer to the usual methods of sensitising, and drying, the tissue, and their drawbacks to those who only require to make use of the carbon process occasionally. These, to an extent, have hitherto prevented many from working the process at all. It is quite true that the trouble of sensitising one's own tissue is avoided by purchasing it ready sensitised, and some years ago the Autotype Company set the example in supplying ready sensitised tissue in small quantities, a practice which, we believe, is now generally adopted. Even when the tissue is bought in small quantities, waste is often entailed, as the purchaser has to take a dozen pieces, when, possibly, only three or four are required for immediate use, and the remainder becomes insoluble before the process has next to be employed.

The usual method of drying the water-sensitised tissue is, of course, bound to be a somewhat slow process, owing to the amount of solution absorbed by the gelatine tissue; and though an improvement was made in it by the Autotype Company about a dozen years ago, when the plan of squeegeeing the sensitised tissue on to ferrotype, whereon it dried under the protection of its own yellow-stained paper, was introduced, even on this system the time of drying occupies some hour or two. These drawbacks are quite overcome by the new quick-drying sensitiser, which is evidently a bichromate salt dissolved in volatile solvents. It is of quite a pale tint, and has a not unpleasant odour. Being affected by light, the bottle containing it should be kept in the dark.

The sensitiser is applied to the surface of the tissue, which is laid on a piece of paper, by means of a Blanchard brush. This is simply a piece of swan's-down, or flannelette, fixed with india-rubber band on the end of a strip of glass. A little of the solution—a very little is required—is poured into a small dish, or saucer. The brush, lightly charged with it, is then passed over the surface, first lengthwise and then crosswise, but in a fairly free and easy manner, so as to avoid regular streaks by traversing the same route repeatedly. It is then hung up to dry, of course, in a darkened or shaded room. The drying takes place in from ten minutes to a quarter of an hour, according to the temperature, and the tissue is then ready for printing. When the tissue has become surface dry a second coating may be applied if desired. This renders the tissue somewhat more sensitive, and, probably, better suited for negatives with very harsh contrasts. But we have not found this necessary even with very contrasty negatives. There is nothing new, it may be mentioned, in sensitising tissue on the

surface only, for such was a frequent practice when the carbon process was first introduced—now more than forty years ago—and the Autotype Company's new preparation has therefore every classical precedent.

In our trials of the new sensitiser, the tissue was dried in an ordinary room with the blinds drawn down. The tissue was pinned on the back of a fire-screen placed on the table. It dried in about fifteen minutes, and was then printed. The sensitiveness, it might be surmised, may be rather less, as so little sensitiser is used, but nevertheless we did not find this to be the case, and precisely the same exposure as for tissue sensitised in the ordinary way was given and proved ample. The prints we obtained were amongst the very best carbon pictures we have ever produced. In developing them, water rather cooler than we are in the habit of employing was used, and the backing paper was stripped off rather quicker than usual, the prints developing quickly and evenly. This will readily be understood when it is considered that it is only the surface of the gelatine—that which forms the image—which is permeated by the sensitiser: the backing paper is not even stained by the bichromates. After several prints had been soaked in the same water, prior to mounting them on the support for development the water was but very slightly coloured, a point deserving notice, as the small quantity of the bichromate salts in this tissue will be a great boon to those who suffer ill-effects in their hand, from working the carbon process.

It may be supposed that the “brush” method of sensitising may give rise to unevenness of the print, but it certainly did not in our experience. The largest pieces we have sensitised in this way, were 10 x 8, and the prints made on them showed no trace of markings, though the brush we used was a somewhat narrow one. The Autotype Company, too, have sent us a 15 x 12 “print,” made on tissue sensitised with the new preparation, applied with “brush.” The tissue was merely exposed to light for a short time and then developed, and the print is of a perfectly even tint all over, without the slightest trace of brush marking. Such a print is of course, a delicate test for evenness.

After what has been said it is scarcely necessary to remark upon the advantages of the preparation. The amateur user of carbon, in particular, will be gratified by the ease with which tissue can be thus sensitised on the day of printing—a boon, surely, in this erratic British weather. Moreover, the process supplies the means of quickly repeating prints which may not be satisfactory in the first instance—a protracted operation by the old process. In short we can commend the preparation to carbon workers, and to those who have not yet made their trial of the process. The sensitiser is sold in bottles containing about 10 oz., at the price of 1s., which includes a “Blanchard” brush.

CREAM CRAYON “SELTONA” POSTCARDS.—The Leto Photo Materials Co. (1905), Ltd., send us samples of a “cream crayon” brand of their well-known “Seltona” product, which they are placing on the market in the form of postcards and “boardoids.” The colour of the surface is a very agreeable pale cream, and the firm matt surface is one which well suits the great majority of work. Both forms of the new variety are sold at the standard prices “Seltona,” namely, twelve postcards and two masks per 1s. packet or twenty quarter-plate “boardoids” at the same price.

## CATALOGUES AND TRADE NOTICES.

The current second-hand list of the City Sale and Exchange, 8, Aldersgate Street, E.C., gives a very long list of bargains in high class hand, field, and studio cameras, shutters, and other apparatus and is a list which anyone in need of fresh apparatus may be recommended to procure, the firm's facilities of suiting the various requirements of customers being very complete. The list is sent free. It contains also the first particulars of the stereoscopic and postcard “Planex” reflex camera.

Messrs. A. E. Staley and Co., 19, Thavies Inn, London, E.C. recognising that good things deserve to be well described, have issued a new and very well arranged price list of their photographic lenses and other apparatus, which is admirable not merely for its stylish appearance, but because the arrangement and typographical facilities reference to it. Very full particulars of the excellent “Euryplan” and “Planastigmat” lenses are, of course, a prominent feature, but there is scarcely any form of modern high-class apparatus

Messrs. Staley are not in a position to supply. Full part of the "Mite" reflex camera, which we review on another page are here given for the first time. The list is quite worth the penny stamps, on receipt of which Messrs. Staley will send it.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JUNE 15.

London Photographic Society. Outing to St. George's Hill.  
London District Photographic Society. Outing to Waltham Abbey.  
London and District Photographic Society. Outing to Highams Park.  
Camera Club. L. and C. P. U. Excursion to Barrow.  
Photo. Art Club. Outing to Woodlands, Emswolden.  
London Photographic Society. Outing to Purley Beeches.  
Ham Photographic Society. Excursion in conjunction with the Coventry Photographic Club, to Binton and Welford-on-Avon.  
North Photographic Society. Outing to Broadway.  
Star Amateur Photographic Society. L. and C. Union Ramble to Barrow.  
Polytechnic Photographic Society. Outing to Dartford.

MONDAY, JUNE 17.

London Photographic Society. "Tri-Chromatic Photography." Hy. J.oley.

TUESDAY, JUNE 18.

Star Amateur Photographic Society. "Making Stereoscopic Transparencies." J. Oliver.  
Photographic Society. "Just Across the Channel." Wm. Rawlings.

WEDNESDAY, JUNE 19.

London and District Photographic Society. "Dry Mounting." Mr. Biss.  
Petition, June 1 Prints.  
Suburban Photographic Society. Portfolio Chat and Criticism of Prints.  
Camera Club. Evening Excursion—Cockersale.  
g Camera Club. Outing to Steyning and Wiston Park.  
Middlesex Photographic Society. "Gum Bichromate." A. H. Piddington.  
North Photographic Society. Survey Excursion to Camp Lane.

THURSDAY, JUNE 20.

London and Provincial Photographic Association. Nomination of Officers.  
North Photographic Society. "The Action of a Lens." W. J. Foster.

### ROYAL PHOTOGRAPHIC SOCIETY.

Meeting held June 11. Mr. J. C. S. Mummery, F.R.I.B.A., (President), declared the exhibition of oil prints by M. Demachy to the members and the public, and read an address on the subject, written by M. Demachy. M. Demachy was of opinion that previous exhibitions at the R.P.S. of a revolutionary process as gum-bichromate has had considerable influence on the growth of that method of printing, and gratifying to see that its exponents were officially represented society. The oil process, after remaining in the shadow for so long, was now striving to occupy the important position it deserved. The whole of the pictures shown were printed on Illingsworth double transfer papers, the different grades of which offered great scope for varied interpretations. M. Demachy was unable to stand how it was ever asserted that numberless facsimiles could be produced by the process. Every square centimetre of the print was in accordance with the worker's judgment, and a facsimile was impossible. According to the artists, notably Lhermitte and Gerroche, who had seen the prints in M. Demachy's studio, the possibilities of the process were very great, and that there was no reason, save ignorance on the part of the photographer, for its values offending the eye. The superiority of the process in reproduction was due to handling alone. It was a useful, but sharp, cut with both edges. M. Demachy hoped that photographers would appreciate the new and great power that local inking placed in their hands. An animated discussion followed, in which Mr. Evershed and Messrs. Tilney, E. T. Holding, F. C. Lamont, W. Thomas, J. H. Gear, S. G. Kimber, Arbuthnot, E. J. and the President took part. The meeting terminated with a unanimous vote of thanks to M. Demachy.

**SUBURBAN PHOTOGRAPHIC SOCIETY.**—The first "Pilgrim's Outing" of this Society took place on Saturday, and was led by H. Snowden Ward, editor of the "Photographic Monthly." The attendance was rather disappointing, since, though the Society numbered over 140 members, only twenty-two enthusiasts, including women, assembled at Wrotham, the centre selected. Three parties, starting from London. One cycled down, arrived early, and got views from Wrotham Hill before the second party arrived. The latter derailed at Kensing about half-past two, picked up a

subject or two at the pretty little village of Inram; then struck the Pilgrim's Road in the hills and tramped in the track of the prehistoric tin merchants along it to Wrotham, passing St. Clare on the way. As the distance was over three miles, they were obliged to leave all the pictures away to their left for a future occasion, or else run the risk of breaking tryst with the third party, which travelled from Catford to Wrotham Station by a later train. One of the pilgrims, by the way, had a heavy whole-plate outfit, which two friends took turns in carrying over the three-mile tramp. At Wrotham the party fell upon the old church, and took it from every possible point of view, external or internal, Mr. Snowden Ward pointing out its peculiarities, the most interesting of which was, perhaps, the unique processional arch broken through the tower to enable processions to make the circuit of the building. Mrs. Carine Cadby was with the party, but had left her camera at home, and, to the regret of everybody, had to leave early on account of her husband's health. After tea at the "Bull" a hearty vote of thanks was accorded to Mr. Ward for the trouble he had taken in the matter. It was practically arranged that he will give the whole day to the S.S.P.S. "pilgrims" who go to Maidstone on July 27, as several of those who made a poor bag in the short time at their disposal at Wrotham are determined to make the trip to Maidstone in the morning, leaving the laggards to follow them down in the afternoon.

## News and Notes.

**BUSINESS CHANGES.**—The old-established business of Mr. Herbert Watkin, Scarborough, has been purchased by Mr. Shaw, of Camberley; and that Mr. Adolf Urban, Leeds, by Mr. Helliwell, Leeds. The transfers were by Messrs. Booty and Co., Walthamstow.

**DISAPPEARANCE OF A REIGATE PHOTOGRAPHER.**—Mr. Arthur Tee, one of the operators in the employ of Messrs. Frith and Co., of Reigate, had been in the neighbourhood of Bath for some weeks taking photographs of the district. He had written from that town to his relatives in a pessimistic vein, and has not since been heard of.

**AT COVENTRY COUNTY COURT** last week, Herbert Pearson, photographer, of High Street, claimed from Joseph Arthur Cross, butcher, 172, Spon Street, £12 12s., of which £5 5s. was for damages to artificial teeth, and £7 7s. for pain and suffering. His Honour gave judgment for plaintiff for seven guineas.

**PHOTOGRAPHIC ARCS.**—Something special in the way of arc lamp lists has come in from the Union Electric Co., Limited, of Park Street, Southwark, S.E. (writes the "Electrical Times"). This is a list (No. 1,362) which deals exclusively with arc lamps for photographic work, a branch of work which has, until now, not received an undue amount of attention in trade lists. The Union Electric Co. has reached, it believes, such a state of perfection in its photographic arcs that it considers they may be called standard patterns. The arcs are illustrated in the pamphlet and are complete with hanging slings, travelling carriages, stands, reflectors, and so forth. Certain of the types listed, for direct current only, are standard patterns for copying and printing work. Open arcs with parabolic reflectors are made for either direct or alternating currents.

**MR. C. CORN**, of the Metropole Studios, Cardiff, and of Islington, London, has taken over the photographic business of Mr. Lundstrom, 16, Hickman Road, Penarth. The premises have been renovated and fitted in thoroughly up-to-date style, and in order to inaugurate what should prove a very popular venture, Mr. Corn held a reception last week, and it is satisfactory to find the head of this enterprising firm, which undertakes all classes of trade work for other professionals, accorded a hearty reception in his new undertaking.

**DEATH OF HERR OTTOMAR ANSCHUTZ.**—It is with regret that we have to announce the death, on the 30th ult., of Herr Ottomar Anschütz, whose name was so long associated with high-speed instantaneous work, particularly that of animals. He was the inventor of a special form of focal-plane camera for this class of work, constructed with such excellence by the Goerz works. He was the inventor also of a special form of cinematograph in which full-size lantern plates were used.

"Hyro" is the name of a private photographic magazine conducted

by a member of the Wimbledon and District Camera Club, with a view to increasing the membership and also of keeping members who are unable to attend the meetings regularly in touch with the doings of the club. Its twelve pages consist of the club notices for the current month, editorial notes on topical matters, reports of club meetings, competition rules, answers to correspondents, and a page for advertisements for which there is no charge. Two of the most interesting features are a tourist article by the secretary, and by way of illustration, and possibly instruction for the younger members of the club, a portrait study, suitably mounted. The whole forms an interesting record of the club's proceedings, and we commend the idea to the notice of other secretaries.

**COMBINED OUTING OF THE LONDON AFFILIATED SOCIETIES.**—On Saturday, June 8, a large number of members of the above-named societies visited Abrook Common, where, owing to the favourable weather, a quantity of interesting work was done. The party then proceeded to Esher for a substantial tea, after which the official group was taken, and speeches made by Messrs. F. J. Mortimer, C. H. Oakden, and Dr. Evershed, the proceedings being concluded with a short entertainment by members of the South London Photographic Society.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.*
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, &c. Two unmounted copies of each photograph must be sent with the fee.*

### PHOTOGRAPHS REGISTERED :—

- J. H. North, 62, Boar Lane, Leeds. *Photograph of the Town Hall, Leeds.*
- Thos. Clegg, Park Studio, Rawtenstall, Lancashire. *Photograph of the Opening of the Carnegie Library at Rawtenstall, June 1.*
- A. Brown, 14, High Street, Montrose. *Four Photographs:—A View of the Ferry, Ferryden, near Montrose. A View of Red Castle, Lunnon Bay, near Montrose. A View of Lunnon Bay, near Montrose. A View of Marine Avenue from Churchyard Steps, Montrose.*

- B. J. Lloyd, 33, Stendale Road, West Kensington, London, W. *Photograph of a Small Flint.*
- F. Overton, 147, Beverley Road, Hull. *Photograph. Being a Copy of a Part Photograph and Part Drawing of New Promenade and Sea Wall, Hornsea.*
- F. C. Macmahon, 23, Academy Street, Inverness, N.B. *Photograph entitled, "The Three Majors" Highland Light Infantry. Photograph entitled, "Sailor's Hornpipe Dancer." Highland Light Infantry.*
- E. E. Carver, 6, Church Street, Maesteg, South Wales. *Two Photographs of the Rev. S. Jackson.*

**NAMING NEGATIVES.**—Can you tell me what is the best way to title negatives? What can you suggest? I might say it is for post-card work.—G. S. P.

The usual plan is to set up the titles in type, photograph down on to a photo-mechanical plate, and transfer by stripping on to the negative, a portion of the film being cut out to receive the title. We have an article in type on the subject.

**COPYRIGHT.**—Am I correct in supposing that one is at liberty to copy and publish photo copies of engravings, issued 1800-1825, without hindrance, and that one had no copyright prior to the Act of 1862?—DOLPHIN.

You will be quite safe in working from the original engravings.

**BLUE-BLACK LANTERN SLIDES.**—I should be very pleased if you would give me some information on the following: I want to make some lantern slides from ordinary negatives, which must be of a decided blue-black colour. I have a trade slide as a sample, and the tone is a cold blue. I have tried various plates (Mawson's, Paget Fast, and Imperial Special) and also various developers (hydroquinone, metol, and pyro ammonia), but can only obtain

a grey or black without any trace of blue. Can this colour be obtained direct, or must I resort to toning with gold? Information regarding plates, developer, exposure (full or under) will be very much welcomed.—BLUES.

Metol is the best developer in our experience for a bluish-black tone, but a pronounced tone is not easy to obtain. The course we think is to develop to a warm colour and tone in a gold sulphocyanide bath. We have got very fine blue-blacks this process.

**LENS.**—It is quite against our rule to express any opinion on the comparative merits of any particular maker's goods. All lenses you name are good. For cabinet portraits, as you say, the lens should not be less than about 12in. focus, but for portraits it would be better longer, as then better perspective obtained, and, as your studio is sufficiently long, we would suggest one of longer focus, say 14in. to 16in. It would be well, for convenience, to have one of about 8½in. or 9in. for very small pictures. A lens of 20in. or 22in. focus, with an aperture of *f*/6, would be very suitable for 15 x 12 groups.

G. H.—This is a question that we are continually answering. has, over and over again, been explained in these columns that when a photographer is paid for taking a photograph, whether portrait, a house, or a view, he has no copyright in the picture that is the property of the one who has paid for its being taken. Again, supposing that the photographer had a copyright in the picture, he can recover no damages for its infringement prior to registration.

DEVON.—Unless you have an agreement in writing you have no much of a case, as there has been no actual transaction. If your mother denies your right to the copyright it is open to you to charge her for the sitting. It is one thing or the other.

W. J. R.—We are sorry that the mistake was ours, as we know your firm would not misrepresent the outfit.

F. S.—Mr. Driffeld has written one number of the "Photo-Minute" (Dawbarn and Ward, 6d.), on the "H. and D." system, but you will not find anything of the slip system in it, as the latter is a method of Mr. Watkins, whose "Watkins' Manual" (any dealer, 1s.), is the book you require.

J. E. A.—Too long for this column. You had better study "Mounting and Framing," by Lambert (Hazell, Watson, and Viney, 1s.).

D. ROSE.—Certainly, you must register the final result, however the result is obtained.

T. M.—Not bad for a week only. T. S. Bruce, whose address you will see in our advertisement pages.

H. J.—Try the Commercial Photo Company, Ltd., Rajar, Ltd., Halifax Photo Company, and Treas Company.

G. K. DEVARE.—The print has been toned both with gold and platinum. Tone slightly in the gold and acetate bath and then with the phosphoric acid and chloroplatinite bath on p. 983 of the "Almanac" for 1907.

R. A. MC.—"The Chemistry of Photography," by R. Meldola, Also "Chemistry for Photographers" (elementary), by C. Townsend. (Dawbarn and Ward, Limited. 1s.)

1. See page 775 of the "Almanac." A brief answer is not possible.
2. O. Schel and Co., 52, Bunhill Row, E.C., is the most likely.
3. There is none.

\**NOTICE TO ADVERTISERS.*—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Reflex Camera Exhibition. Steps are being taken by the Photographic Convention to transfer the collection of cameras and prints to Hereford for the Convention week.

Further again in an editorial to the movements of reflex cameras and reference to different classes of work. (P. 459.)

Mr. Arthur Marshall expresses the highest opinion of the reflex universal instrument, and particularly because of the means of judging of the "photographic quality" of a subject.

Mr. Martin Duncan, writing on the use of the reflex in Nature photography, sums up some of the essentials of an instrument to be specially for that purpose. (P. 461.)

Notes by Mr. F. C. Tilney on the photographs in the exhibition, regarded as pictures, appear on page 463.

The Professional Photographers' Association reports its intention with a case of canvassing frauds. (P. 470.)

Mr. Hurley Lewis has published a brief interesting confession as to his aim in photographic portraiture. (P. 467.)

An interesting exposure of "spiritualism" by means of the camera was made at Leeds last week. (P. 458.)

Some figures for German imports and exports of photographic requisites for the first three months of the present year.

A widespread interest is taken in Germany in the protection of portraits from disfigurement by advertisements, etc. (P. 458.)

The conclusion of the review of modern progress in colour-sensitising. Mr. E. J. Wall appears on page 464.

Chromatic plates and flexible films are among the patents of the week. (P. 468.)

A suggestion of a lens of uranium glass has been made by Houdaille. (P. 458.)

## EX CATHEDRA.

**The P.C.U.K. at Brussels.** By their unanimous vote last week, the Council of the Photographic Convention of the United Kingdom recommended to the forthcoming general meeting, to be held on Tuesday in the Hereford week, the acceptance of the invitation from the Association Belge de Photographie for the Convention to make the Belgian capital its meeting-place next year. The friendly overtures of the Brussels society with which the leading amateur and professional photographers in Belgium are associated, should, we think, meet with the approval of the Convention as a whole, although the selection of a Continental meeting-place will send the Convention outside these islands for the first time. However, no more favourable venue than Brussels could be named. A comfortable night journey brings the traveller there from London in little over twelve hours, and at a cost (return) of twenty-five shillings. Moreover, the lower cost—something like one-half—of hotel expenses in Belgium will more than compensate for any extra railway fares which those in the North of England would have to pay. For those who prefer a shorter sea journey and daylight, a passage of three or four hours via Dover and Calais, or fifty-five minutes via Dover and Calais, will take them from London to Brussels in about eight hours. One factor, amounting almost to a guarantee of a successful Belgian convention, is the intimate knowledge, acquired from constant visits for so many years past, which Mr. F. A. Bridge has of the country and of the many highly picturesque spots easily reached from the capital. We hope the invitation of the Association Belge will be accepted.

\* \* \*

## Reflex Cameras.

It will interest those who are unable to see the present collection of cameras and photographs at the "B.J." office to learn that almost all of them will be exhibited at the forthcoming Photographic Convention of the United Kingdom, to be held at Hereford from July 15 to 20. There are one or two makers who are unable to grant the loan of their instruments for that occasion, but the majority, according to information received as we go to press, will allow conventioners to have the opportunity of inspecting their manufactures.

\* \* \*

## The Flattery of Imitation.

It has been pointed out often enough how photographers and painters interchange their points of view. The modern amateur pictorialist hangs on to the skirts of impressionism for some reason best known to himself. The painter, or, rather, the cheap illustrator, copies the hit-or-miss snappings of the camera user, giving us a foot and an outstretched arm of a figure, "trimming off" the

remainder of his anatomy. A very accomplished draughtsman in lead pencil shows at the New English Art Club a drawing called "St. Pancras," which is more like a bad photograph than anything else in the world. It may be described as a "bald-headed" print in platinum of a street scene, very flat in tone, and a trifle hard in its edges. Such, at least, would be the ordinary criticism of it from the mind of the average photographic critic. The irony of the situation is that the little sketch has delightful qualities, and is obviously the work of a man of talent—Mr. Muirhead Bone, in fact. Here we have art mimicking, unconsciously, a photograph at its worst, and we find the result good. Can there be any other explanation of so anomalous a state of things than that the hand of man endures a trifle in art with some mysterious charm denied to the purely photographic record? Fortunately, the mechanical work of photography has its own charms also, denied, in turn, to the hand of man. In fact, the two things are essentially different, and cannot be regarded from the same point of view. Such instances as the above only endorse and confirm this contention.

\* \* \*

#### **Landscape Protection in Germany.**

Some interesting light on the care with which the scenic beauties of the country are preserved in Germany is shed by a recent lecture delivered in Munich, which we find abstracted in "Nature." In all parts of Germany, but particularly in Bavaria, quarrying and forestry have been done under State superintendence, in order that a check might be set to the disfigurement of scenery by these operations, as well as by the erection of advertisements, telephone cables, and the like. The traveller in the picturesque and unfrequented byways of Bavaria finds much to be thankful for in the absence of disfiguring acts of vandalism, and one can only express a wish that some similar official aid might be granted to the bodies which in this country have had the same good aim before them, although we have cause to be proud, as Prof. Conmentz, the author of the paper, points out, of the lead taken by London in the retention of woods and forests as public places.

\* \* \*

**A Photographic Exposé of "Spiritualism."** We are glad to see our contemporary, "Truth," in whose pages the legion forms of trickery are pilloried, giving prominence to a recent exposure of an alleged medium in Leeds. The "medium" was a man named Chambers, whose manifestations of the materialisation of spirits have been accepted in spiritualistic circles in the North with mingled veneration and rapture. Some of his dupes were so satisfied of the genuineness of the phenomena which were produced by his mediumship that, with the idea of converting sceptics, they arranged for a photographer to be present at a private séance, with a view of securing negatives of some of Chambers' familiars. After the usual hocus-pocus on the part of the medium and the singing of hymns by the audience, the manifestations commenced, and from within the cabinet where the medium was concealed a variety of spirits made their appearance. One of these was a spirit known as "The Signor," who spoke broken Italian, and was announced as the medium's chief guide. "The Signor" was persuaded to give a sitting to the photographer, and by means of a flashlight exposure a couple of excellent negatives of the spirit form were obtained. The resultant photographs were published in the "Leeds Mercury," and admirably illustrate the bogus character of the manifestations. "The Signor" is obviously the medium himself, divested of his clothes and shrouded in a sheet, which he

is holding in his mouth in order to conceal the lower part of his face. The quaintest element in "The Signor" spiritual attire, however, is his headdress, which is formed out of a chest-protector which Chambers was wearing.

\* \* \*

#### **Uranium Glass Lenses.**

At a recent meeting of the Société Française, Colonel Houdaille exhibited results obtained with a lens made of uranium glass, and recommended it on account of screening effect. He found that in a thickness of millimetres it absorbed ten per cent. of the luminous rays and fifty per cent. of the photo-chemical, or presumably the blue. There is, therefore, an appreciable improvement in the colour-rendering when using orthochromatic plates. Incidentally, it is remarked that there is far more even illumination over the plate than with ordinary glass, the reason being that the convergent lens of uranium glass being less thick at the edges than at the centre, absorbs less of the oblique rays, and automatically acts the rôle of a compensator. No details are given as to photometric determination of this point, data which would be required as the absorption by the glass of the lens is the most important factor in producing unequal illumination. It is remarked also that only in very few combinations could it be used, and not in a lens of the anastigmatic type.

\* \* \*

#### **Coloured Lenses.**

It is stated that M. Atout Taille suggested in 1892 the use of yellow glass for the lens, but the idea of using coloured glasses dates much further back—to 1853, in fact, though then the idea was to use violet or blue glass to ensure perfect achromatism. We believe that Sir V. Crookes was the first to suggest the use of yellow-coloured lenses, in order to obtain better colour-rendering, the idea has been revived times out of number. Sir V. Abney has also suggested coating one of the surfaces of the lens with coloured collodion. Colonel Houdaille, in face of the fact that uranium glass cannot be used for making anastigmats, suggests that a suitable yellow glass would soon be made if the need arose.

\* \* \*

#### **The Photographic Salon.**

The fifteenth Photographic Salon announced to open its doors on September 13 at the gallery of the Royal Westminster Colour Society, Pall Mall East, and to close them on October 26, which is also the closing day of the Royal Photographic Society's Exhibition. The conditions of entry remain unaltered, except that, in the case of France, a special committee composed of M. Robert Demachy and Colonel C. Puyo will make the selection in Paris. In previous years, the avowed aim of the Limited Bazaar is "to exhibit only that class of work in pictorial photography in which there is distinct evidence of personal artistic feeling and execution." As also intimated last year, "pictures sent for exhibition to any other exhibition open in London at the same period are liable also to be disqualified," an announcement which may be emphasised to new comers into the exhibition field as a gentle reminder as to the way they should proceed if they would make friends with those who will sit in judgment in Pall Mall East—not only next September, but in other September years, and whose memories in such matters as the exhibition of duplicates are reported to be little short of infallible. Entry forms for the exhibition are obtainable from the honorary secretary, Mr. Reginald Craigie, 5A, Pall Mall East, S.W., and entries must, if packed, reach Messrs. Bourlet and Sons, 17 and 18, Nassau Street, London, on August 29, or may be delivered in all their native loveliness at 5A, Pall Mall East on September 2.

## REFLEX CAMERAS.

## II.

In the previous article we essayed the, to us, unnecessary of emphasising the advantage of the reflex type of camera. Yet, as we then said, it is not easy to convince occasional experienced workers of the gains derivable from a system which affords a short cut to a facility of working which they themselves have attained by steps which were painful and slow. If we were uncharitable we might attribute their disparagement to not altogether generous motives, for it is no nicer for a clever hand-camera worker to have the wind taken out of his sails by a recruit with a reflex than it is for a teacher of music to see a pianola being delivered in his neighbourhood. In addition, however, to the general points raised last week, there are some others relating to the comparison between focussing cameras and those of the reflex pattern, and others refer to differences among these latter themselves.

The objection alleged against the reflex is that it must, by its very nature, be used from a lower point of view than is often desirable, on account of the exaggeration of such a lower point bestowed on the height of buildings in the foreground. To this it must be said that at two patterns of reflex on the market provide for use at an eye level by means of a mirror in the hood, which reflects the image on the ground glass, and gives the photographer an actual, though inverted, picture, which he can focus and compose as he wants. We have heard, too, of heroic measures as holding the reflex upside-down when arms extended upwards, and viewing the image through the downward hanging hood; but we cannot offer recommendations as to the convenience or certainty of such a method. It may be said, however, that so far as focussing is concerned, this operation may be done at whatever level, the camera then raised to the eyes, and selection of the field made by judgment with the eye, and it will be found possible with practice to use the ordinary reflex with great certainty in this way, as the difficulty—the focussing—does not enter into the operation. In fact, the method is precisely that most commonly used by photographers of sporting and other events in which rapid movement occurs. With the best apparatus usual in the case of such subjects first to get the camera in focus on a certain spot, where the moving figure comes, but at the time of the actual exposure to keep the focus fixed on the subject itself, not on any image of it in the finder. The camera is best at the level of the eyes, and to be done, and a reflex camera is quite as suitable as any other for such work.

This brings us to one other point in connection with the photography of objects in rapid motion, namely, the desire for the instantaneity of action of the reflex camera and the ordinary focal-plane shutter such as the Goerz-Entz, which may be taken as the standard type of the ordinary focal-plane camera. Does the reflex respond as satisfactorily to the release in exposures of objects appearing to the camera or moving across its line of sight at high speed? The question, by whomsoever put, amounts to a confession of inexperience in high-speed photography, for the reason that the personal equation enters into all work when making the exposure, and the practised worker will mentally anticipate the arrival of the oncoming runner or cyclist in order that the exposure may be taken place when the latter has reached the pre-arranged point. In the case of a reflex we are not prepared to say that the interval between pressure on the shutter and the exposure is any longer, but admitting that the adjustment lies in the automatic anticipation of the point at which the release is made, a point which may

be observed when watching the object itself or its image on the ground glass of the reflex.

We may now say a word on the use of the reflex in the making of hand-camera studies of figures in streets, markets, and other places where the chief considerations are to keep the camera out of sight and to be able to bring it instantly into action. In these respects the reflex, saving its power of accurate focussing, is not so suitable as the well-known types of box scale-focussing camera, although, with the hood down and a focussing scale fitted, it is not one whit less suitable. If we were anticipating any proportion of figures among other subjects, we should certainly fit a scale for 10 ft. and 15 ft. to our reflex camera, and should expect to find these marks of service; or we should use a quiet moment to get a figure in focus on the ground glass on about the scale we wanted, and then, shutting down the hood, use the camera thus set. This is solely for the sake of securing figures before they had discovered they were being photographed. The reflex, it should be added, supplies a most ingenious method of securing the same end in the provision of a mirror placed on the lens panel at an angle of 45 degrees to the axis of the lens. The image is thus received at right angles to the direction in which the camera is actually pointing, and thus allows of figure studies being obtained under the very noses of the subjects. We cannot speak from our own experience of this method, but several well-known hand-camera workers have used it with great success, and Messrs. Adams regularly supply one form of it as a convenient attachment.

Coming now to the adjustments of the reflex camera itself, one of the first points of advantage is the co-relation of shutter and mirror, by which (1) the shutter cannot be wound while the mirror is up, or (2) the mirror always falls again after an exposure, unless purposely latched up, or (3) the shutter can be wound but not kept up if the winding key is turned while the mirror is up, thus exposing the plate. The last-named tells us at once that the mischief has been done, which is something, though not so good a movement as No. 1 or No. 2, of which we prefer No. 1 for the reason that on this system it is apparently easier to provide a gentle release than it is on No. 2, in which, in the commercial patterns, the setting lever for the mirror acts also as the release.

A point of importance as regards time exposures is the rapidity with which the shutter can be adjusted to give them. Usually, those cameras in which the shutter alone is used in giving the time exposure are the better in this respect, but in our opinion the best of all arrangements is to open the focal-plane shutter to its full aperture before exposure commences, and use a lens cap or lens shutter for the time exposure. This plan is preferable on account of the freedom from the vibration to which a large shutter such as the focal-plane is liable. There is one other point to which we must refer. Although it is one for individual consideration, yet it should not be overlooked in selecting a camera. It is the disposition of the focussing screw in relation to the shutter release. In some cameras these are placed on opposite sides; in others, near together on the same side. The first system is adopted in order to focus a moving object up to the instant of exposure, following it in the ground glass with the focussing screw, and keeping the finger of the other hand upon the release. In the second system the left hand is given the duty of holding the camera firmly, and the right that of focussing the subject and releasing the shutter, on the principle that the most accurate work is done, in the case of rapidly moving objects, by first focussing on a point in the stationary portion of the view, and waiting until the object just reaches it before making the exposure. Both systems have their supporters among users, though it must be said that

the makers by a large majority adopt the former. However, it is not a difficult matter to have a camera converted from one to the other.

In regard to the other features of a reflex camera, we think we may dismiss them as those of a good hand-camera;

those we have discussed in the foregoing notes relate more particularly to the reflex mechanism, and will, it is hoped, be of service to our readers visiting the present exhibition or studying the reviews of the apparatus there shown which appeared in our columns last week.

## THE REFLEX HAND-CAMERA AS A UNIVERSAL INSTRUMENT.

[As a commentary on the present interest in the reflex exhibition at the "B.J." house, and in the facilities afforded by the reflex type of hand-camera, more than usual importance may be attached to the following article by Mr. Arthur Marshall, the well-known maker of oft-medalled exhibition pictures, from the fact that, with one exception, all Mr. Marshall's exhibition work has been taken with his reflex camera in the first instance. An instrument of this type, as the article points out, is of immense value in judging of the "photographic quality" of a scene.—Eds. "B.J."]

THE qualities in the reflex type of camera which make it nearer to the ideal hand-camera than any other type are the following, viz. :—

1. The exact extent and composition of the image actually affecting the plate may be seen.
2. The degree of the illumination of the subject or strength of the light may be better judged.
3. Full use can be made of any type of lens.
4. Architectural studies can be made with better results.
5. To the study of insect life it is indispensable, or of birds on the wing.

The first point is of the greatest value to the picture-maker. Seeing the image the actual size it is represented upon the plate, with its groupings, composition, balance of lights and darks, its atmosphere and delicate tones of light, or the details in the depths of the shadows—are advantages which not even the stand-camera possesses; more particularly where the study of figures and expressions in face is concerned. These alone give a value to the reflex type which, to my mind, places it far and above any other kind. The brilliant finder of the ordinary type of hand-camera where scale focussing is adopted is most misleading, and not to be relied upon where certainty of work is a consideration—and I presume that it always should be. The pictures appear too small to judge of their most important qualities—namely, grouping and composition, and the proper relation of light to dark—and though the image is very pretty and bright upon the brilliant finder, it is absolutely no index whatever to the actual value of the rays of light which find their way to the plate when the exposure is made.

With the reflex finder this is reversed. The strength of the light acting upon the plate is seen upon the ground glass, and its strength is judged accordingly.

### The Reflex as Exposure Guide.

It is astonishing how easily the eye may become accustomed to the value of such light, and by careful observation of the same the length of exposure necessary may be easily judged also. This, again, is a most valuable feature possessed by the reflex camera, and to which there is no corresponding advantage in the other types of hand-camera.

Exposure tables may be all right as an approximate guide, but seldom have I found the subject which I was taking quite fit any of the headings so carefully worked out. Therefore, I would much rather trust to my own judgment and rely upon the appearance of the image upon the screen and expose accordingly. By means of the reflex camera this is quite possible, but with the ordinary type it is not.

There is no reason why there should be any spoilt plates at all with a reflex camera if a capacity for observation and the exercise of a little judgment are possessed by the photographer, the appearance of the image upon the ground-glass carefully noted, and the exposure made accordingly.

Different types of lenses can, I believe, be adapted to most reflex cameras, especially if the long-focus variety be used. This, again, is an immense advantage.

### An Optical Outfit.

To my own camera I have as a standard lens a Zeiss "Protar" with single and double combinations for ordinary use, a Becksteinheil Unar working at  $f/4$  for rapid work. (To this I have a telephoto attachment of Dallmeyer's.) Then I can use a 10 x 8 Dallmeyer stigmatic lens working at  $f/6$ , which gives very much larger image upon the plate, and which is useful for photographing figures and groups some distance away which would require a rapid exposure. There is certainly no form of hand-camera that I know of where so much is possible. It has all the good points of a stand-camera, with the additional advantages of portability and the power to follow moving objects and to keep them in focus at the same time.

### The Reflex in Architectural Work.

The valuable architectural work possible with the reflex camera gives it an additional value. No matter how carefully one may look through an ordinary finder, or how accurately the levels in the camera are adjusted, the small scale of the finder renders it more or less uncertain whether the lines of the subject are upright. There is always a moment when the camera leaves the levels to look at the finder, and that moment is usually long enough an interval for the perpendicular to be lost and the picture spoilt. With the reflex finder, carefully ruled with marginal lines and vertical and horizontal lines in the centre there is no possible chance of the subject being out of perpendicular, and it can be watched right up to the moment of exposure. For exterior views of buildings and streets there could be nothing better, and except for cases where an extreme degree of rising front is necessary nothing more is required than with a reflex camera can give you.

The study of insect life and birds on the wing (a branch of photography which is becoming very popular) may be better carried out by means of a reflex camera than by any other type. A bee in a flower, a spider on its web, may be represented life size with ease by means of the reflex, but with any other type of hand-camera there would be little chance of obtaining a satisfactory result.

### In Judging of "Photographic Quality."

The quality in a subject which one might call "photographic" is better appreciated and more easily judged by the appearance of the image upon the ground-glass of a reflex than through the ordinary brilliant finder—to my mind a most important point, as the photographer is frequently led astray by the prettiness of a subject when seen through the ordinary finder, and as frequently disappointed with the result of the exposure. The nearer the relation of tones in a subject the more capable is

good photographic rendering. In no other hand camera, ever, is it possible to ascertain the value of this tone relation by means of the finder.

To enumerate a few of the features, where perhaps it is hoped the improvement will in the near future be effected, is perhaps natural after having spoken so highly of the reflex type camera. To secure the reversing frame for upright and horizontal pictures perhaps a little greater bulk is necessary in the camera itself, and a corresponding increase in weight; but, the painter, when he goes out in search of pictures, does not mind carrying his stool, easel, umbrella, paint-box, etc.; should the pictorial photographer make so much of portability and weight? Efficiency and utility are sacrificed often for the sake of portability.

The noise of the simultaneous release of the shutter and mirror is at times rather alarming, and attention should be given to remedy this. It is really the only real disadvantage which I have found in its use. The particular make of instrument which I have used since it came out is very assertive in this matter; and upon one occasion, when snapshotting the King of Spain some two or three times at twenty yards' range, a tremor or alarm seemed to affect his courtiers. It is equally offensive upon many occasions where silence would be valuable; but even with this somewhat unpleasant defect, to my mind it stands to-day head and shoulders above any other type of camera for all the qualities which make a useful, valuable, and, better still, a reliable hand-camera.

ARTHUR MARSHALL, A.R.I.B.A., F.R.P.S.

## THE REFLEX CAMERA IN NATURE PHOTOGRAPHY.

In reference to the number of examples of natural history work in the reflex exhibition, the notes by Mr. Martin Duncan as to the essentials for success in such photography are of special interest.—Ebs. "B.J."]

There are the difficulties with which the naturalist-photographer has to contend, for the majority of his models are shy, restless, wayward creatures, frequently making the greatest demands upon his patience and skill, ere a successful picture can be obtained. Therefore, any piece of apparatus that will materially help to lighten his labours and give an increased certainty of obtaining a desired result is indeed a boon; and, without doubt, is a really good reflex camera. I say a really good reflex camera, because there are, unfortunately, many forms of this camera on the market that are, for various reasons, more or less useless for accurate work.

The ideal reflex camera for nature work will have many points in its construction that would not be very important in ordinary hand-camera work or press photography, but which are of vital importance when photographing animals, birds, insects, etc. First and foremost, the camera must be thoroughly well made throughout, because it will have to stand plenty of rough, hard wear. It must be perfectly unobtrusive in appearance, preferably covered with very dark green or black leather, and on no account must there be any brass or other bright metal fittings to reflect light and attract attention.

The camera must have a long extension of bellows, and must be rigid when racked out to its greatest extension. This is a point in which many reflex cameras fail, being only provided with sufficient extension for a short focus lens. Therefore, a reflex camera that is intended for nature work should have an extension of at least fifteen inches.

And here a word or two about lenses suitable for natural history work with a reflex camera may not be out of place. On account of the small size of the image on the plate, and the abrupt and more or less grotesque foreshortening of all objects, produced by a short-focus lens, it is most unsuitable for all natural history work. Really, for natural history photography, one should not use a lens of less than 7 in. focus on a quarter-plate. On account of its close definition and large working aperture, the best modern stigmat type is the ideal lens for the naturalist-photographer, the majority of his exposures have to be as short as possible, and not infrequently have to be made under anything but ideal conditions of lighting. Therefore, a lens working at  $f/5.6$  is an additional step towards success, enabling him to take a fuller exposure to his plate. Hitherto, the great drawback to the use of a telephoto lens for nature photography has been the small working aperture of the lens itself and the considerable extension of camera bellows required. Recently, Messrs. Emil Busch have introduced a new type of telephoto

lens, which I believe has a great future before it for natural history photography. It is called the "Bis-Telar" lens, has a working aperture of  $f/9$ , and does not require a long extension of camera. I am very pleased with the results I have obtained with one attached to my reflex camera; the definition is crisp

Larva of the Privet Hawk Moth. By F. Martin Duncan, F.R.P.S.

and excellent at full aperture, and as the lens works at  $f/9$ , one can use it for moderate hand-camera exposures in comparatively dull weather. When using any form of telephoto lens on a reflex camera, it is most important to hold the camera as rigid as possible at the instant of making an exposure.

To return to the construction of the camera. The mechanism

of the release of the focal-plane shutter and the mirror should be as simple in character as possible; and if it can be easily got at for repairs or any necessary adjustment, so much the better. It is most important that the setting of the focal-plane shutter, adjustment of its speed, and size of slit, should be of rapid, easy, and silent accomplishment, for one generally has no time for fiddling about with more or less troublesome mechanism, whilst clicking sounds are apt to draw attention to the camera, and cause the hasty retreat of the model. The focal-plane shutter should be capable of giving exposures ranging from 1-10th to 1-100th of a second; and that it will work smoothly and accurately at its slowest speeds is of far greater importance than its capability to give an extremely short exposure. The simultaneous release of the mirror and

Peacock Butterfly expanding its wings preparatory to first flight after emerging from pupa. By F. Martin Duncan, F.R.P.S.

focal-plane shutter should be as silent and free from vibration as possible.

The focussing hood, when in position, should be deep, perfectly rigid, and shaped to fit closely against the face, so that all light will be shut off from the front surface of the focussing screen when the face is pressed against the hood. The focussing hood is really a very important factor, as it has to take the place of the ordinary voluminous focussing cloth, and unless properly constructed is apt to prove a very poor substitute. The reflex camera should be fitted with a good rising front and a reversing back. The front should also have a flap lens hood, to act as a sky shade, which is a very necessary and important adjunct, making a very great difference in the clearness of the image obtained on the negative, and enabling one to work against the light.

Where the reflex camera is of such very great value and

assistance in nature photography is in the power it gives one of following all the movements of the subject to be photographed on the focussing screen, with the plate-holder in position and the shutter set, enabling one to focus critically up to the instant of making the exposure. Anyone who has attempted with an ordinary stand or hand camera to photograph some restless bird, animal, or insect, that is constantly changing its position, will at once realise what a boon the reflex camera is. The photographs which illustrate this article were all taken with a reflex camera, and are characteristic examples of subjects which are very difficult to photograph satisfactorily except with a camera permitting one to follow

Willow-Wren and Young. By F. Martin Duncan, F.R.P.S.

up to the instant of making the exposure. The young willow wren, for instance, was constantly changing its position hopping about after its mother in a way that would have made it almost impossible to obtain a picture with an ordinary camera.

To succeed in photographing natural history subjects, one must have a real love for the work, patience, determination and "learn to labour and to wait." Make yourself thoroughly familiar with the life and habits of your models, and study the environment in which they live, for with such knowledge your pictures will not only be far more natural and characteristic, but you will be able to approach much nearer to your subject. Never be in a hurry, but always be ready. Nothing alarms wild creatures more than quick, sudden movements.

F. MARTIN DUNCAN, F.R.P.S.

**DEATH OF MR. R. F. REYNOLDS.**—We regret to have to announce the death, on the 1st inst., of Mr. Richard Freshfield Reynolds, of the well-known firm of Reynolds and Branson, Ltd., Leeds. A short time ago Mr. Reynolds, who was forty-six years of age, fell in the street and sustained compound fracture of one leg, which, though not at first considered serious, led to complications, the immediate cause of death being heart failure.

**THE ROTARY PHOTOGRAPHIC COMPANY, LTD.**, have compiled a list of the causes of, and remedies for, the failures most frequently met with in working their "Rotary" carbon and colour photography processes. The tabulated form of the list makes it easy of reference, and the information should prove useful, not only to the amateur in his early experiments, but also to the advanced worker. A copy

of this list will be sent post free to any of our readers on application to The Rotary Photographic Company, Ltd., 12, New Union Street, Moorfields, London, E.C.

**NORTHUMBERLAND AND DURHAM FEDERATION OF PHOTOGRAPHIC SOCIETIES.**—The annual field day of the federation is fixed for June 27th when, at the invitation of the Morpeth Y.M.C.A. Camera Club, visit will be paid to that town. An interesting programme has been drawn up, and, provided the weather be favourable, an enjoyable and profitable time is anticipated. Parties will be formed to visit places of photographic interest in the town and surrounding district, and the Morpeth Camera Club will award a silver medal for the best picture taken at the outing. Full particulars may be obtained from Mr. James Whittle, 30, Bridge Street, Morpeth.

## SOME NOTES ON THE REFLEX-CAMERA PHOTOGRAPHS AT THE "B.J." HOUSE.

is perhaps claiming a little too much to say of reflex cameras, at by their works ye shall know them. In an exhibition devoted entirely to achievements by this latest development in photographic apparatus, there does not appear a sudden, dumbfounding advance in selection of subject and focussing. A technical expert (alas! I am the reverse) might be able to point out how certain facilities have resulted in certain felicities; but, in an ordinary way, a man would have to resort to guesswork if he went, say, round the autumn show at the New Gallery pointing his finger upon the prints due obviously to reflex cameras.

What might be said with some certainty is, that if so and so had possessed a reflex, he would have saved himself that lamentable focussing and that unfortunate selection. The ordinary camera working without a focussing screen is a hit-or-miss affair. It is often as not one does not get what one aims at. Vexation of spirit, to say nothing of ejaculations and expletives, await the amateur camera worker who trusts to his own calculations or to a view-finder alone; but he may make his developing a more salutary operation by the adoption of the mirror attachment. In my own humble and unguided efforts I have been a victim to the false clear finder bought separately and attached precariously to the top of the camera. This contrivance was purchased under the assurances of the counter-man that when fixed in its place it was rigid and dead-true. As a matter of fact, it was easily bent off by the caressing touch of a coat-sleeve; and its images were positively misleading. Its pictures, though small, were strangely spacious. A figure, in three paces, would shrivel up to a quarter its size: insignificant foreground objects occupied all the field. Verticals were never perpendicular in its pictures; but when they were made as upright as possible, they were worthlessly aslant in the negative. This little toy was soon abandoned. Guesswork was a deal safer.

With all these safeguards, prophecies, and checks, we should expect to find an exhibition of reflex camera work all that photographs should be. But there is one thing these cameras do not do; they do not give the user taste. Consequently, though all the exhibits at 24, Wellington Street are immaculate in the matter of focussing, they are not all faultless in the selection of subject. True, there are few that show men as pigs tramped down in half, or trepanned and amputated; but there are one or two that display awkwardnesses of composition clearly the fault of the camera, but the artistic peccadillo of the photographer.

On the other hand, it is fair to say that, with these few exceptions, the selection of the subject is obviously the best that could be made under the circumstances. Now and then there is one of those unusually happy arrangements wherein chance seems to have done more than all that forethought and design and taste and art together could have done in a week.

### Mr. J. H. Stewart's Yacht Photographs.

For example, the two yachts, "Sonya" and "Adela," which Mr. A. Stewart has captured, are exquisite. Their beauty of line, their swift, sweeping movement, the precision and crispness of their presentation, and their silvery scheme of tone, so true and so such fascinating gradation—all these beauties are photographic. Impressionistic they may not be, and I, for one, am fond of it. They are not even human visions of the things; but they are beautiful, nevertheless. It is not claimed, of course, that nothing but a reflex could have given them. The subjects

are common enough. But the point is that Mr. Stewart could see them swooping along without looking at them: his exposure was made just when they nicely filled the space of his plate, and when they looked right. A view-finder's word to "go" would have been, by comparison, an approximate business: the reflected image was a certainty.

### One Drawback (!) to Reflex Cameras.

Most of the pictures by H. Bairstow are similarly satisfactory; but his larger selection admits, naturally, more than two things, both first-rate. In his picture "Striking a Bargain" he has some men and women bartering sheep in the road of a provincial town abroad. It is all capitably arranged except for an empty upright panel-shaped piece on the right-hand side, which is awkward and pictorially unpleasant. His "Vegetable Market, Evreux," is likewise good in all but one respect, namely, a heap of cabbages which makes a painfully obvious triangular mass right in the middle of the composition. The one drawback to reflex cameras is that they allow no excuse for such pictorial sins, the blame for which they shovel unmistakably and unmercifully upon the operator. Mr. Bairstow's best selection is perhaps that entitled "Ahoy There!"

"Bother the Children," by W. Thomas, is a most neatly caught episode of a mother and two youngsters in a street of St. Ives, Cornwall. Quite happy in its arrangement and setting, it is an ideal genre subject ready to hand, and would paint well.

The Italian scenes of Percy Lewis are well known. They are always well chosen. His "Woodland Scene" is likewise a capital subject.

Even at the risk of being mutilated into piffle, I would suggest that, with a reflex in his hand, W. F. L. Wastell should have avoided bad balance by allowing less at the right-hand side of his "Adversity," a piece of first-class character photography, showing Cockney flower-girls upon the steps of the Piccadilly Circus fountain. But it was unkind of him to call a poor ugly old woman, in another example, "Herself the fairest flower of them all."

A choir, or some other such ecclesiastical procession, scuttling through a street into the portal of a religious building, is the subject S. S. F. Fletcher calls "A Procession, Cancale, Brittany." It was a thing worth securing, for it has humour, giving the undignified side of sacerdotal decorum. The flying vestments doubtless recommended it to Mr. Fletcher as a fitting subject for his "Birdland" camera.

This remark brings us to Mr. Pike, his "Kites and Eagles," and to all the other natural history pictures which photography has revolutionised. Riley Fortune, F.Z.S., has a "Flying Gannet," and Charles Kirk, "Gannet on Wing"—a nice distinction, which only ornithologists will appreciate.

Comedy is represented by a poor little birdling ruthlessly held in a horny hand and looking up to its captor with hatred and scorn whilst its beak opens with the denunciation "You Brute!" For tragedy we have a horrible octopus sucking the life out of a crab. It is a shocking and nauseating performance beautifully presented. Our only consoling thought before us is that, after all, that sort of thing is only what the crab himself has often done.

There are plenty of other pictures of natural history and portraiture displaying the facilities of the various types of reflex cameras. The examples here touched upon are neither the worst nor all of the best.

F. C. TILNEY.

## A REVIEW OF RECENT WORK IN COLOUR SENSITISING.

### IV.

SINCE the previous notes have been in type, an article by T. Thorne Baker (1) has appeared, in which he states that "certain dyes sensitise the plate in the region of waves of greater length than the wave length of the band of absorption of the dye, and other dyes sensitise the plate for a region of waves of shorter length. *In other words, the maximum of sensitising is sometimes to the left, sometimes to the right of the band of absorption.*" The italics are mine, and I think that this statement requires confirmation. So far as I am aware there has been absolutely no case recorded, nor can I find on reference to notes of my own sensitising experiments, any such shift of the sensitising towards the violet end.

It is obvious that if confirmation of Mr. Baker's statement is forthcoming it will seriously affect the now accepted theory of colour sensitisers, that is, that Kundt's law is the explanation of the shift towards the red, unless, of course, Mr. Baker's statement refers to but few dyes, and one accepts the old and erroneous adage that exceptions prove the rule. I may possibly be allowed to add that Mr. Baker gives no data as to the dyes that prove his statement, nor does he publish any spectrograms, and that the statement must be accepted with all reserve.

There is one other point in connection with the use of dyes and sensitising, and that is the influence of the chemical nature of the dye. This question was examined by Eder (2), who, from an examination of over 140 dyes, comes to the conclusion that there is no regular connection between chemical constitution and sensitising action.

#### Cyanine Sensitisers.

One would naturally expect that dyes of one family such as the cyanine and isocyanine derivatives may all be sensitisers, though in different degree possibly, because the substitution of nitrate for iodide, chloride, sulphate, or bromide would presumably have less action on the nature of the dye than a substitution in the grouping of the dye base itself. But as Eder points out, the bromo, chloro, iodo, and benzyl derivatives of fluorescein are all sensitisers, yet the introduction of the nitro radicle at once decreases, if it does not actually destroy, sensitising. Rosaniline is a sensitiser, but rosaniline sulphonic acid is not; here the introduction of the sulpho radicle  $\text{SO}_3\text{H}$  or  $\text{SO}_3\text{Na}$  has destroyed the sensitising action. On the other hand, benzaldehyde green and its sulphonic compound are both sensitisers. As a rule the introduction of the sulphonic group has but little influence on the dye as a dye beyond making it soluble in water, and as a rule making the dye an acid dye that is capable of combining with a metal base.

Dr. E. König (3) says: "The number of practically useful dyes is relatively small. Good sensitisers have been found in all classes of dyes. Dyes differing most widely in constitution and composition, of greater or less stability to light, frequently show very similar behaviour as sensitisers." It is obvious then that like chemical constitution is no criterion of like sensitising power.

MM. Lumière and Seyewetz (4), dealing with the relation between chemical constitution and sensitising, state that it is well known that the dyes which are used to sensitise gelatino-

bromide of silver for red, yellow, and green do not act only by staining the gelatine, thus forming a sort of screen which absorbs the complementary colours, for if this was so all colouring matters having the same absorption spectrum ought to be sensitisers. But experience has proved that this property is only common to quite a limited number of dyes, and that, of a number having the same absorption spectrum, some will sensitise whilst others are absolutely devoid of this property. The number of dyes of acid character is as great as those with basic properties. Testing almost all the known dyes, about 650, and classifying according to their constitution all the dyes which produce any effect, the authors noted that the sensitisers belong to a very limited number of classes of dyes, and that they were found in relatively large numbers in each of these classes. Thus there were found about:—

- 4 sensitisers amongst the derivatives of diphenylmethane, a group which comprises really very few dyes;
- 30 sensitisers in the phthaline or rhodamine group;
- 12 sensitisers in the rosaniline group;
- 10 sensitisers in the quinoline, acridine, and phenylacridine derivatives;
- 5 sensitisers in the thiazol or azothiazol colours;
- 10 sensitisers in the azodiamine derivatives of benzidine or its homologues.

The relatively large number of dyes endowed with sensitising powers which are found in the above few groups and isolated dyes in others would seem to prove that it is alone amongst the dyes belonging to the above groups that we must look for sensitisers. And what appears to confirm this hypothesis is that in the groups containing the active dyes, whatever they are, the sensitising action is always produced in the same region of the spectrum by dyes possessing the same absorption spectrum.

#### Sensitising Groups.

One may admit, then, the principle that in the dyes there is a group which gives to the dye its sensitising power. We may designate these groups "sensitising groups." To establish their composition it is sufficient to find what are the elements common to sensitisers of the same class. But it will be seen that they are the same as the chromophorous groups of the dyes. The following is the constitution of this group:—

Derivatives of diphenylmethane:

Derivatives of triphenylmethane:

Derivatives of acridine and phenylacridine:

Derivatives of thiazol or azothiazol:

Azo dyes (diamines):

It is difficult to determine with accuracy the sensitising group of the quinolines, but it would appear to be very analogous to those of the triphenylmethane derivatives.

It will be thus seen that there is really a relation between

<sup>1</sup> Rev. Suisse, 1906, No. 11, p. 310. The full title of the paper is "Sur la Théorie de la Sensibilisation aux Couleurs par les Colorants," par M. T. Thorne Baker, F.C.S. (Résumé complet des recherches récemment communiquées par l'auteur à la "Royal Photographic Society of Great Britain.") Although dated 1906, No. 11, this issue appeared in May, 1907.

<sup>3</sup> Vogel's "Photochemie," 1906, p. 318.

<sup>4</sup> "Résumé des Travaux Publiés," 1906, p. 75. Although no precise statement is made, I gather that this paper was read before the Congrès des Sociétés Savantes, 1898.

sensitising power of a substance and its constitution, variable to that which is found for its colouring properties.

### The Composition of Dyes.

This brings us to the question of chemical constitution from point of view of the photographic experimentalist who is a dye chemist. He is in most cases dependent on the dye manufacturer for his supply of dyes, and, except in special cases, has absolutely no guarantee of the purity of his dyes. Thus a common thing in dye practice for manufacturers to use dyes which are not adulterated but yet are diluted with substances, such as dextrine, or salts which are necessarily in the dyeing process, such as Glauber's salts. Taking consideration also the extremely complicated nature of the compounds used in the manufacture of a dye, one cannot be surprised if by-products, other than those usually intended, are produced. How then is the photographer to determine whether the sensitising action is due to the dye or the secondary product? For photo-chemical investigations it would be absolutely essential, therefore, for pure dyes to be used. In connection with this point it may be well to point out that the name of a dye is no criterion of its chemical constitution. As an example of this kind I may quote my experience with cochineal A, a dye I once used for the red screen in three-colour work. It is derived from naphthionic acid and *b*-naphtholdisulphonic acid and is actually an azo dye. Running short, some new dye was ordered, not from the same maker, and I received eosine lake as the correct thing. Naturally, the absorptions were totally different. Again, take the case of erythrosine, which is a tetraiodo fluorescein salt, but erythrosine B is the bromotetrachlorofluorescein compound. Again, erythromycin and BMP are again different. Again, there are five or six different eosines, though we understand eosine as the bromofluorescein compound.

References have been repeatedly made to Eder and Valenta's *Träçe zur Photochemie und Spectralanalyse*. This is the most complete and collected work on the subject, and contains the examination of over 600 dyes as sensitisers; it is, therefore, an extremely valuable work of reference. To those who wish to undertake the examination of dyes as regards their sensitising powers the above work is indispensable, as is also some text-book on dyes themselves.

### How First to Test a Dye.

The first thing to do with a dye is obviously to examine its absorption spectrum, as from this some clue, even if a rough one, can be obtained as to the region for which it will sensitise. Generally an absorption spectrum varies as the solvent of the dye, but the difference between an aqueous and alcoholic solution is not always great. The use of solvents such as chinoline or anything which cannot be used in the sensitising of a plate, is obviously absurd. Sometimes a difficulty may be found in dissolving a dye in water. In that case alcohol, or equal parts of alcohol and water, should be tried, and both rectified and methylated spirit, for a dye may dissolve in the latter and not in pure alcohol. The use of alcohol also, if only to form a stock solution, will often precipitate a diluent such as dextrine, etc. It is not advisable always to filter a dye solution; it is preferable to let any sediment settle, and use the clear solution, for, in filtering, the dye may be precipitated or adhere to the filter paper.

The measurement of the absorption of a dye is not an easy matter unless one has a spectro-photometer; but for photographic work probably the easiest method is to make a solution of known strength, measure as accurately as possible the limits of its absorption band or bands, and then dilute the solution to a definite proportion and again measure the limits of the absorption, naturally in the same thickness of solution, when the limit of maximum absorption may thus be roughly estimated and persists the longest, that is with decreasing strength.

The edges or centre of an absorption band are utterly useless, for, as Baly (5) says, "A great deal of quite valueless work has been done upon the absorption bands of solutions; many of the measurements have been based upon purely arbitrary scales, and further, insufficient attention has been paid to the position of the maximum absorption of a band. A measurement of a band simply stating the wave-lengths of the edges is of no use, because very often the middle is not the darkest part."

That the position of maximum absorption is not the centre of a band and *vice versa* is beautifully shown with a strong solution of ivy or parsley leaves; in fact, any solution of chlorophyll, if strong enough or thick enough, for the two terms are convertible, will show it. The absorption extends for the alpha band from about  $\lambda$  6,500 to  $\lambda$  5,280, and the D line is the centre of the band. Dilute the solution or reduce the thickness to one-tenth, and the band now extends from  $\lambda$  6,400 to  $\lambda$  6,000 and the D lines are no longer in the band at all.

Considering the extremely satisfactory sensitisers which we have, it is an open question whether, except for purely scientific experiment, the examination of dyes as sensitisers pays, except for special purposes. The work is extremely laborious, for one must test the dye in various strengths, though here its tintorial power is some rough guide, and one must also try the action of ammonia. The addition of silver nitrate, whilst possibly permissible for special work, is not so for average use, as plates thus treated will not keep.

One has to determine also whether a dye in conjunction with colour-sensitising also depresses or increases the blue-sensitiveness of a plate, or if for spectroscopic work whether it increases the sharpness of the Fraunhofer lines, which it may do without increasing colour-sensitiveness. For testing plates one should use not only a spectroscope but a colour chart, for a dye may act well in the spectroscope and yet prove of little value for practical work. In both cases to test the limit of sensitising it is always advisable to use a colour screen, such as the red filter for three-colour work. The use of such a filter, for instance, in spectroscopic work eliminates the scattered light in the spectroscope, and enables one to obtain records of the red end without undue exposure or solarisation of the blue end.

This device is well known in visual work (6). M. Stefanik has by the same device visually observed the infra-red up to  $\lambda$  10,000, and M. Millochau (7) has by this means photographed to  $\infty$  in the infra-red on Lumière ordinary plates bathed with a concentrated solution of chrysoidine, and using a liquid filter of chrysoidine malachite green and aniline violet.

Precisely the same principle is, of course, used in ordinary photographic work when a yellow filter is employed with a colour-sensitive plate. The filter does not increase colour-sensitiveness, it merely reduces the action of the blue and violet rays, and enables one to prolong the exposure sufficiently so that the much lower sensitiveness of the plate to the yellow and green rays comes into action, and yet not obtain over-exposure or solarisation with the blue.

### The Screening Action of Dyes.

There is one action of a dye which so far has not been touched upon, and that is the "screening action," which was, I believe, first actually drawn attention to by Von Hübl (8). He says: "The silver bromide must be dyed by the dye, and there is no purpose, except an actual prejudicial one, in adding excess of dye to the emulsion—that is, more than the silver bromide can take up. The collodion is coloured by the excess of dye, and the rays of light must penetrate the stained collodion in order to reach the silver bromide grain. The collodion acts then as a

<sup>9</sup> "Die Collodium Emulsion," Halle, 1894, p. 74.

coloured filter, which practically absorbs those rays for which the silver bromide was sensitised. The disadvantage of too strong a staining is very plainly seen with cyanine, as faintly stained emulsions such as are scarcely blue are incomparably more sensitive than those which contain larger quantities of dye."

It is generally admitted that the use of a prismatic spectro-scope is not so advantageous as the diffraction grating or a replica, because of the crowding together of the less refrangible rays. Still, this very fact may enable one to detect slight colour-sensitiveness, which might otherwise be overlooked with a grating. Whether, when such action is so faint that it requires this additional help to detection, it is of any practicable value is quite another matter.

If a grating is used care must, however, be exercised that the ultra-violet spectrum of the second order is not superimposed on the red and infra-red, and thus lead to totally erroneous conclusions. The ultra-violet can, of course, be eliminated by the use of aesculine, or if, as suggested above, a red filter be used, then the use with this of filter yellow K will save all trouble in this direction.

#### Colour-Sensitive Photometer Paper.

Although it may be said to be by some rather far-fetched, yet there is no harm in calling attention to Andresen and Eder's work on the use of colour sensitised bromide paper as a normal photometer paper, and for this reason that Eder<sup>(9)</sup> has proved that "bromide and chloride of silver films sensitised with dyes behave analogously both in development and by direct blackening; the sensitive zones suffer a change in both

cases in approximately the same regions of the spectrum, and show analogous maxima and minima of action. In certain stages of exposure and development the curves of the two kinds of density run approximately parallel." Eder has found a rule to apply generally to silver chloride and to bromide of silver, strong cyanine, formyl violet, cyclamine and chinoline red, but not with alizarine blue bisulphite or some indulines and nigrosines. Much obviously depends upon the composition of the emulsion, notably on the presence or absence of iodide.

This method might be of value as a rough test of the sensitive powers of a dye, and Andresen's method<sup>(10)</sup> of preparing paper is as follows:—Raw paper is bathed for five minutes in solution of potassium bromide, 61 gms. in 1,000 c.c.s. of water and dried. Then in the dark-room it is sensitised by floating for two minutes on a 12 per cent. solution of silver nitrate and washed to remove all the soluble salts. The washed paper is then bathed for five minutes in a solution of:—

Sodium nitrite .....	6 gms.
Rhodamine B 0.5 per cent. alc. sol....	8 c.c.s
Water .....	200 c.c.s

and dried in the dark.

Andresen recommends chlorophyll for red, rhodamine B or rose-bengal for yellow, erythrosine or eosine for green, and auramine for bright blue.

It is quite possible that one might, by means of this process, make a paper which could be used with suitable filters to test the amount of coloured rays in white light, or the exposure for three-colour work. Still, this is merely a suggestion.

## A ONE-MAN PHOTOGRAPHER ON HIMSELF.

ERAL delicious touches of humour enliven the contribution of last week to our contemporary, "The Photographic News," on its page devoted to "My Best Picture, and Why I Think So." There Mr. Lewis, still the gentlest and wittiest of Bohemians, and generally established in the old studio of Mr. Gambier Bolton in St. John's Wood, says a few words on a portrait by himself of Mr. Alexander Haddon, which, as all friends of Mr. Haddon know, is "Haddon to the life." Mr. Lewis is one of the "professional photographers"—we use the phrase *faute de mieux*—of whose work is individual, as, indeed, it ought to be, for the end of the process to the other no other hand but his own. As a professional photographer he is before his time, but the historian of photographic portraiture will write him down as one in an age of utterly commercial work, produced only what might be thought worthy of his sitters and himself, and we know of no artist who could do more. While the midget maker drives his motor, our friend Furley is probably taking a penny 'bus to St. John's Wood, there to spend an evening over the printing of a single portrait, we are glad to think that he, and such as he—not many of them—are rescuing photography as an art of portraiture from submergence in the great gulf of commonplace. Of his portrait Mr. Lewis

in self-defence I must join with those who have expressed dissent in the title of this interesting series. For, surely, were the poor 'professional' publicly to declare any individual work his best, as a means of vengeance from slighted sitters were awakened, and his own would but court calamity. Indeed, I have been told that it has become the fashion for the personal worker to assure each and every sitter that unto him or to her it has been vouchsafed to receive the artist's choicest achievement!

Resisting the temptation to play for safety by sending you a particularly masterly landscape, made per 'Tick-a,' I submit, as one of my favourite works, this portrait of Mr. A. Haddon, as embodying two somewhat heterodox views, which I venture to hold with regard to modern photographic portraiture.

Thus, it attempts nothing more than a simple but literal likeness, the sitter is clothed in the habit of the man as one best knows

him; and the creases, facial and sartorial, are his own. It actually includes—from one aspect, anyhow—the entire head of the sitter. I don't like old scapels littering up my trimming desk.

"It is focussed as well as the lens allows, and therefore would not readily be mistaken for, say, my friends Mr. Snowden Ward, Mr. Coburn, Mr. Bernard Shaw, or other frequent victims to the portraitist's bow and spear. By way of confirming the correct impression, however, Mr. Haddon's name is legibly embodied in the print itself.

"What breadth it possesses is arrived at in the arrangement and lighting of the subject, and not by disarrangement of rack and pinion, diffusion, or other aids to incompetence; and—now speaking personally—it is some record of one to whose research and skill our craft is for ever indebted."

## A NEW HIGH-POWER GAS LAMP.

QUITE recently (writes Mr. Richard Böhm, in the "Times" Engineering Supplement) a new high-power lamp has been invented which, when connected to an ordinary gas installation, produces increased pressure automatically. Lucas, the inventor of this lamp, has previously rendered great services in the sphere of lighting, and he has now succeeded in constructing a lamp of considerably greater illuminating power than those previously introduced. It is a well known fact that the illuminating properties of the incandescent burner largely depend upon the proportion and the uniformity of the mixture of gas and air. The ordinary Bunsen burner does not comply with these conditions, since with normal gas pressure the flame is only furnished with about half the quantity of air necessary for complete combustion. This proportion should be one part of gas to 2.8 parts of air, and therefore the flame, in order to obtain the requisite amount of air to complete the combustion, must draw supplies from the atmosphere in the immediate neighbourhood of the burner. In the Welsbach light this lateral absorption of air takes place all round the mantle, and is associated with a definite lowering of temperature, so that the gas consumed in the burner does not produce the same heating effect which can be obtained with a more perfect mixture of gas and air in the burner itself.

In 1895-6 Denayrouze endeavoured to produce an improvement in these respects by arranging in the mixing tube of the burner a small fan driven by the electric motor, and in this way he was able to produce a much more intense light centre. These high-power burners have been introduced in France to a somewhat large extent, but they are only intended for medium light centres of several hundred candles. Whilst the Denayrouze burner must derive the current necessary for driving the small motor from a special source of electricity, Lucas, in his new high-power lamp, has removed this drawback by arranging in the upper part of the lamp a thermopile, which is actuated by the heat contained in the spent gases. The current necessary for driving the motor in the lower part of the lamp is thus generated by the lamp itself in burning.

In construction the new lamp is exceedingly simple. A thin tube suspended from the main pipe serves to feed the gas into two mixing tubes, and between these lies the armature of a small electric motor. In order as much as possible to avoid friction the vertical shaft of the armature runs on a point in a brass tube filled with oil. A fan fixed on the same shaft draws in air from below, and forces the intimate mixture of gas and air through two lateral conducting tubes into a small chamber, from which the mixture passes to the burner orifice itself. The hot gases rising from the flame meet the sections of a thermopile, arranged in the upper part of the lamp. This source of electricity supplies the current for driving the small motor, and the wires terminate in two minute brushes of silver wire on the commutator of the motor.

Thermopiles have been known for a long time. In the present case a special form of construction was necessary, which should be, above all things, durable. Lucas made use of two metallic alloys, one consisting of copper and aluminium, the other composed of copper and nickel. These alloys, which are extremely heat resisting, are employed in the form of metal strips, which are soldered hard at the heated end, and soft at the cool end. The thermopile is arranged in the form of a disc, and is capable of being easily replaced. Equally

ingenious are the small motor and fan, so that these parts are not likely to get out of order, even after long usage.

On starting the lamp it burns at first under normal gas pressure, with a flame of little illuminating power. Presently the hot gases in the chimney heat up the inner junctions of the thermopile, and generate the current, so that the motor soon begins to drive the fan at a high speed. After half a minute the fan already rotates at a speed of 2,000 revolutions per minute, and the lamp emits a light of from 1,100 to 1,200 Hefner candles, consuming about 900 litres of gas per hour.

Professor Wedding has subjected this new high-power lamp to a searching examination, and has found that it gives far better results than the existing pressure gas lamps. It possesses the great advantage that it is independent of any machine, and can be attached to any ordinary gas installation and set into action at once.

In the tests of the lamp it has been found that after 1,460 hours' use it still continues to work efficiently, and the oiling only requires to be renewed after 500 to 600 hours' burning. The incandescent mantle lasted 70 hours, which is about the same as in the well-known compressed gas lamps. The mantle holder lasts 300 hours. The manipulation of the lamp is simple.

The Lucas lamp must be regarded as an important step in advance in the sphere of high-power gas lighting. It affords a simple solution of a problem which has been under investigation for a number of years. Its utility in practice has been put to the requisite proof by a year of uninterrupted observations, so that it may now be said to be ready for general introduction.

### THE REFLEX CAMERA EXHIBITION.

THE opening of the exhibition of reflex cameras and of photographs illustrating their use, at the house of the "British Journal" last Thursday, has proved an immediate attraction to numbers of photographers, and each day, from 10.30 to 4.30, the hours during which the exhibition is open, the "little gallery" at 24, Wellington Street has been the scene of a constant procession of photographers, anxious to inform themselves of the facilities possible by this latest triumph of the camera maker's art. Among those who have thus signified their approval of the action of the "British Journal" in arranging the exhibition are: Messrs. A. L. Adams, J. and W. B. Appleton (Taylor, Taylor, and Hobson, Ltd.), A. W. W. Bartlett (Kodak, Ltd.), Francis T. Beeson, J. Brown (Kodak, Ltd.), F. P. Cembrano, J. B. Cunningham, A. D. Doncaster (Sanger-Shepherd and Co.), F. Martin Duncan, F.R.P.S., Dr. E. R. F. Evershed, A. Horsley Hinton (Editor "The Amateur Photographer"), E. T. Holding, J. McIntosh (secretary Royal Photographic Society), H. G. Ponting, P. R. Salmon (Editor "Photographic Dealer"), O. Sichel, H. C. Spink, W. L. F. Wastell, and J. B. B. Wellington.

Since the exhibition has opened one apparatus not reviewed last week has been added to it, in the shape of the "Studio" reflex camera, by Messrs. O. Sichel and Co., a description and illustration of which appear this week, under 'New Apparatus.' Professionals and amateurs alike have evidently been interested in the wide range of possibilities which the reflex camera opens out, and it would seem as though the attendant at the "British Journal" exhibition, by whom the apparatus is explained to visitors, will find his time fully occupied until the closing date of the exhibition, July 6.

**THEFT OF PHOTOGRAPHS.**—A respectably attired man, giving the name of William Gregson, photographer, of no fixed abode, was brought up in custody, at the Tiverton Police Court on Saturday, charged with stealing photographs, valued at £2 19s., the property of Sidney James Cowell, photographer, of 35, Chapel Street, Tiverton. Mr. W. H. Martin, who prosecuted, applied for a remand, which was granted.

**ROYAL PHOTOGRAPHIC SOCIETY.**—It has been arranged that the society's annual dinner will be held as soon as possible after the close of the exhibition. Messrs. A. W. W. Bartlett and Leslie E. Clift have been appointed joint hon. secretaries, and members of the council will act as stewards. Tickets will be issued later in the year at 7s. 6d. each, and all members of the society are requested to assist in making the function a success.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been made between June 3 and June 8:—

**COPYING, ETC.**—No. 12,778. Improvements relating to the copying, enlarging, or reducing of photographic or other prints or the like, said improvements being also applicable to the taking of direct photographs. John Shaw McCormick, 100, Wellington Street, Glasgow.

**DEVELOPING.**—No. 12,900. Improvements in and relating to means for developing photographic plates, films, and the like. Percy Albert Craven, 11, Maiden Lane, London.

**CAMERAS.**—No. 13,108.—Improvements in photographic cameras. George Russell Nicholls and John William Turner, 48, Crescent Road, South Norwood Park, London.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**FILMS.**—No. 1,454. 1907. The invention relates to an improvement upon the patent No. 10,372, 1905, and has for its object to provide a film which, upon being immersed in water, photographic developing solution, or the like, remains impervious to the action thereof. One or more coatings of gelatine are so applied to smooth backing or support, composed of glass, paper, or other suitable material, as to be capable of easy removal when desired. When dry, the gelatine surface is coated with a solution which, upon drying, leaves a residual layer impervious to water and the ordinary developing solutions, fixing, or toning solutions, and the like. Such a solution may be of a nitrocellulose, caoutchouc, gutta-percha, resin, balsam, solid fat, paraffin, or the like, or mixture of such solutions, and if necessary liquid oils may be added thereto in order to increase the impermeability and pliability and to reduce the cost of manufacture.

When this impervious coating is dry, the gelatine film is stripped from its backing, and its side, which has been applied to the latter, is in turn rendered impervious in like manner, the gelatine film being thus protected on both its sides. John Henry Smith, Wallishofen, Zürich.

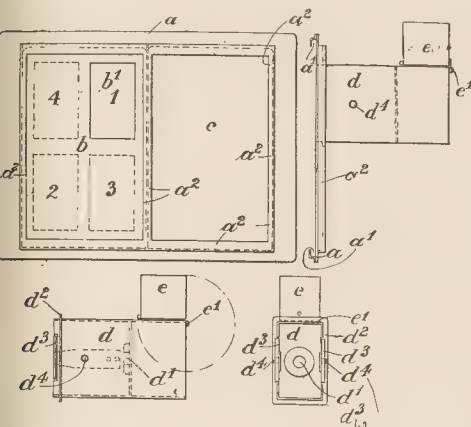

**ORTHOCHROMATIC PLATES.**—No. 13,561. 1906. The invention relates to improvements in the preparation of isochromatic plates whereby a yellow screen may be dispensed with. For this purpose a quantity of naphthol yellow, or any suitable allied yellow colouring substance of the naphthol series, is added to, and mixed with, the emulsion, and the mixture so produced is applied to the plate and allowed to dry thereon to form the film in the usual way, and the plate, when dry, is ready for use.

It is found that by adding about one ounce of a solution of naphthol yellow or other yellow colouring substance of the naphthol series, containing about one gramme of the colouring matter to one ounce of water, to twenty ounces of emulsion, a mixture is obtained which is in every way suitable for the purpose of the invention. Edwin Ebenezer Burnett, 2, Heber Road, Cricklewood, London, N.W.

**MIDGET PHOTOGRAPHS.**—No. 19,383. 1906. The claim is for an apparatus consisting of a combination of a plate holder (having a shutter), and of a screen having an aperture, together with guides by which the screen may be attached to the plate holder in various positions. When it is desired to take an impression on the plate in its holder or dark slide at the back of the frame the camera is fixed to the screen *b*. The shutter of the dark slide is then withdrawn, thus exposing the plate. Then the lens *d* in the camera *d* is uncovered by any suitable shutter, so that part of the plate corresponding to the aperture *b* receives an impression. This part is marked 1. The shutter is then closed and the camera *d* is taken from the screen *b*; this lens is then withdrawn with its guides *a*<sup>2</sup> and is turned in its own plane and replaced in its guides. The camera is again attached

the screen *b*, and the aperture *b*<sup>1</sup> and camera *d* then occupy the space 2, and after the shutter is withdrawn another impression may be received on this part of the plate. The shutter is again closed and the camera *d* is detached from the screen *b*; the screen is withdrawn from its guides *a*<sup>2</sup> and is turned over, after which it is again inserted in its guides *a*<sup>2</sup>. The camera *d* is

again attached to the screen *b*, but this time it is on the opposite side of the screen *b*. The third impression will therefore be the part marked 3. The camera *d* is then removed from the screen *b*, this latter is turned in its own plane, it is inserted in its guides *a*<sup>2</sup>, the camera *d* is again attached, and the fourth impression will take place at 4.

The screens *b* and *c* are then transposed, and four other impressions may be made on the other half of the plate in exactly the same manner as the first four impressions were made. Herbert Pettesworth Page, 123, Park Lane, Clissold Park, Stoke Newington, London, N.

**FAST LOADING FILM PACKS.**—No. 11,884. 1906. The claim is for a film pack, comprising a sealed package of daylight loading films for use in a camera, consisting of a rimmed inner sheath carrier, characterised by flanged rims and ends in one piece to hold the films and guide them in passing from front to rear and forming a chamber at the front to receive a bundle of tabbed films, of a chamber at the back in which the tabs lie before use, either with or without stop plates to engage shoulders on the extension tabs or backings to prevent withdrawal of the films from the sheath; and with or without the elements of a light-valve to trip the extension tabs and a rounded nose at the top over or around which the extension tabs are placed before use, and the films drawn after exposure; constructed substantially as described. The full specification, containing forty-five diagrams, is necessary to describe the details of the arrangement. John Edward Thornton, Altrincham, Cheshire.

**EXPANDING BOXES.**—No. 12,004. 1906. The invention consists of a hanging box or camera, intended to be loaded by the user in a dark room, with tabbed films or films in a pleated strip, constructed with an expanding valve or valves to close upon the tabs a greater or less number of films as may be required. John Edward Thornton, Altrincham, Cheshire.

## New Trade Name.

**ELAH.**—No. 292,715. Chemical substances used in manufactures, photography or philosophical research and anti-corrosives. P. Herman et Cie., 11, Rue du Milieu, Petit-Ivry (Seine), France, manufacturers. May 4, 1907. Address for service in the United Kingdom is c/o H. Sefton-Jones, 322, High Holborn, London, W.C.

**S. ABELL**, who has for many years carried on business as a photographer at Knaresborough, died on the 8th inst., after a long illness, at the age of 68.

## New Apparatus, &c.

The "Studio" Reflex Camera. Sold by O. Schel and Co., 52, Bunhill Row, London, E.C.

Messrs. Sichel write us their excuses in reference to their omission to send us in time for the opening of the reflex exhibition a camera of this type, which they supply specially for the purposes of the professional portrait photographer. The instrument has now reached us, and may be seen among the other apparatus in the exhibition room at our offices. For the benefit of those, however, who may not be able to examine it there we may say that it is solely a stand instrument, taking a half-plate, and built square for either vertical pictures or figures, and horizontal ones for groups. The camera is very solidly constructed on an extended baseboard, and allows of no less an extension than 26 inches from lens to plate. It is entirely free from elaborate mechanism, the mirror being simply raised by a cord and allowed to fall again by its own weight. As it does this, however, very quietly, it is well suited for the requirements of the studio. It may also be actuated with the "Antinous" release. The camera is provided with detachable hood, it has a swinging lens front, and costs, without the hood, 8 guineas. The latter is supplied at an additional price of one guinea, and the "Antinous" release for 10s. 6d.

**THE "SWINCAM" CAMERA STAND.**—In order to meet the increasing demand for a tripod of the "Swincam" type, and possessing the same mobility of head, at a lower price, Mr. Butler has designed a new pattern, "Model B," of this well known patent, the price of which for a stand 4ft. 6in. high is £1 11s. 6d. The special advantage of this stand is that the tripod head is so adjusted that it can be readily fixed in any position at will, thus enabling the operator to bring his lens to any desired angle and fix it there, and the stand should be of value to many photographers, both amateur and professional, who desire to specialise in their work. Full particulars may be obtained on application to Mr. William Butler, 20, Crosby Road, Southport.

## CATALOGUES AND TRADE NOTICES.

**Messrs. HARRINGTON BROS., LTD.**, of London and Cork, have just issued a new wholesale price list of chemicals for use in analytical and scientific research, photography, manufactures, etc. The list, which appears to be of a very exhaustive character, may be obtained upon application to Messrs. Harrington Bros., Ltd., at their London address, 4, Oliver's Yard, City Road, E.C.

**THE WESTMINSTER PHOTOGRAPHIC EXCHANGE, LTD.**, have just published a new edition of their illustrated catalogue, in which all matter has been thoroughly revised and brought up to date. The list contains a well-selected assortment of apparatus and accessories, and is abundantly illustrated. The Westminster Photographic Exchange also call attention to the fact that they supply goods, where required, on the "easy payment" system, particulars of which, as well as copies of the catalogue, may be obtained from them at 119, Victoria Street, London, W.

**A NUMBER OF ENTRY FORMS** for the exhibitions of the Royal Photographic Society and the Photographic Salon have been sent us for distribution, and we shall be pleased to forward copies to any of our readers on receipt of a halfpenny stamp for postage.

**CHARGE OF EMBEZZLEMENT.**—Last week, at Tiverton, William Gregson, of no fixed address, was charged with embezzling money belonging to Sidney Cowell, of the Tiverton common lodging-house. Prosecutor said when he met the prisoner, about two months ago, he said he was down on his luck, and he suggested that there was scope for a photographic business at Tiverton. Witness bought the necessary apparatus and prisoner agreed to take and develop the photos for food, lodging, and clothing. One day, after collecting money from customers, he absconded. When arrested at Exeter £1 15s. of £2 5s. collected was found on him. He denied that there was a partnership. On the other hand, Gregson said there was a partnership, equal shares, but he could never get any money out of Cowell. He contended he was entitled to money he took. The mounts were printed "Cowell and Co." Cowell said his wife and father-in-law represented "Co.," and not the prisoner. The Bench said, as the business appeared to have been conducted in a very loose way the fine would only be £1 or fourteen days.

## New Materials.

"Empire" Plates. Made by B. J. Edwards and Co., Castlebar Works, Ealing, London, W.

In introducing these plates primarily and chiefly for portrait photography the old Edwards' firm comes before its public with very good credentials, for, as users of the Edwards' isochromatic plates well know, fineness of grain, so important in portrait photography, is a characteristic quality of emulsions of their manufacture, and is found, too, in the newly introduced "Empire." In two other important respects the new plate, in our experience of it, is particularly well fitted for the special work for which it is advanced; it is of high speed, and in development behaves itself as a soft working plate—that is, one with which it is not easy to pile up density quickly, and thus produce the hard gradation in the high-lights of the subject which is beyond the powers of the printing process. There are, of course, occasions when the attainment of such a high density is a great advantage, but portrait making under the usual conditions is not one of them, and we think that softness of working is a quality which should be carefully chosen in a plate intended for studio use. The measurement given below by Dr. Sheppard of the gamma infinity of the plate shows it to be nicely adjusted in this particular respect.

As an idea of the speed of the plate we may mention a series of exposures we made with a hand camera in a dull afternoon light (about 4 p.m.), which gave a reading of the Wynne meter of about 40 seconds. At  $f/6$  our exposures were from 1-15 to 1-25 of a second, and the results surprised us for their rendering of detail, whilst the absence of halation in the cases of branches against the sky furnishes us additional proof of the good quality of the plate as regards fineness of grain and consequent immunity from halation. They developed fairly quickly in a desirable clean manner, and altogether the new production is one upon which both the makers and professional photographers who have occasion to use them may be congratulated.

The measurements which, for the information of those who base their work on sensitometric quantities, we are accustomed to give from determinations by Dr. S. E. Sheppard, are as follows:—

Inertia (to screened acetylene with H. and D. pyro-soda) .....	28
$\gamma\infty$ (measuring the density giving power of the plate) .....	1.48
K (velocity constant of development in decinormal ferrous oxalate at 20 C) .....	170
$t\gamma$ (time of development for a gamma of 1 with standard developer) .....	7.4 mins.

We have only to add that the plate is marketed at popular prices by Messrs. Edwards and Co., by whom inquiries as to their new introduction will be readily answered from the Castlebar Works, Ealing, W.

THE NEW ENGLISH ART CLUB.—At this semi-annual show of paintings the visitor must tread warily, pick out his pleasures, and scorn to be bothered with the trash. There are three water colour and two oil colour sketches which will amply repay a visit, and at a fraction over 2d. each are cheaply seen. Those photographers who are still doubtful as to what an impression is should see these marvels of shorthand drawing and colour and tone, by John S. Sargent, R.A. Perhaps the finest achievement is the "Balustrade," part of a marble staircase of an Italian garden, in sunlight and shadow. There are likewise some of Rich's strong and manly water-colours, looking like early British classics. The street scenes of Francis Dodd, which we have previously admired so much, are a little less fine in oil colours, though the "housebreaking" incident of No. 64 is first rate. Professor Brown has a portrait of himself under title "An Amateur of Fencing." He has given himself a bruise on the right eye. In his "Mill" he seems to have solved the painter's puzzle as to what is the colour of the shadows in trees under sunlight. In A. Rothenstein's "Laundry Girl" we see no drawing, no colour, no feeling, no beauty, and no subject. If possible, we see still less of either in the childish pencil scrawls of girls misnamed "studies"; the work of a man who, by being one of the most log-rolling of cliques that pollute the atmosphere of art, has wriggled himself into some notoriety.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

FRIDAY, JUNE 21.

Aberdeen Photo Art Club. Indoor Meeting.

SATURDAY, JUNE 22.

Bradford Photographic Society. Y.P.U. Excursion to Hull and Beverley.  
Bowes Park and District Photographic Society. Outing on River Thames.  
Aberdeen Photo Art Club. Outing to Durris.  
Hackney Photographic Society. Outing to Hornchurch.  
South London Photographic Society. Outing to Leigh-on-Sea.  
North London Photographic Society. Outing to Rye House and Broxbourne.  
North Middlesex Photographic Society. Outing to Ruislip and Ickenham.  
Leeds Camera Club. Yorkshire Photographic Union Excursion to Hull and Beverley.

MONDAY, JUNE 24.

Southampton Camera Club. "The Making of the Print." H. Essex.  
Bradford Photographic Society. Ramble to Garden, Wood Hall.

TUESDAY, JUNE 25.

Hackney Photographic Society. "Short Papers." J. Linley and J. Reeve.  
Coventry Photographic Club. Outing to Allesley and District.  
Birmingham Photographic Society. Social Evening.  
Wallington Camera Club. "Short Papers."  
Manchester Amateur Photographic Society. Exhibition of Work by the Portraiture Class.

WEDNESDAY, JUNE 26.

North Middlesex Photographic Society. "Double-transfer Carbon." Ch Beadle.  
Devonport Camera Club. Outing to Lanhydrock (Bodmin).

THURSDAY, JUNE 27.

Handsworth Photographic Society. "Gothic Architecture." E. G. Collins.  
London and Provincial Photographic Association. Annual General Meeting.  
North London Photographic Society. "The Hand Camera." C. H. Madden.

### THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at the Royal Photographic Society, 66, Russell Square, W.C., on Friday, the 14th inst. Present: Messrs. F. A. Bridge, Alfred Ellis, S. H. Fry, E. H. Martin Jacquette, A. Mackie, D. Prodder, C. H. Skillman, E. Scam and R. Fellows Willson.

The hon. secretary reported that, in accordance with instructions he had inserted a full-page advertisement in the BRITISH JOURNAL OF PHOTOGRAPHY, on behalf of the Association, and the result had been satisfactory; 27 new members had joined during the month.

The meeting considered an application for membership from Mr. R. Dührkoop, of Hamburg, on the point whether foreigners non-resident in the United Kingdom or its colonies were eligible. It was decided that Mr. Dührkoop be admitted, as there was nothing in the constitution of the Association excluding such members, and there was a precedent, two photographers in business in the United States being members, and that the hon. secretary write to Mr. Dührkoop cordially welcoming him.

An invitation was read from the Editor of the BRITISH JOURNAL OF PHOTOGRAPHY to hold an exhibition of professional work at the offices of the "B.J." It was decided to accept the invitation, and to the date either December or January next. A long discussion took place upon the lines upon which the exhibition should be organised. Eventually it was decided that, as the best means of securing a collection of professional photographs which should be of educational value to professional photographers, a number of the leading photographers should be invited to contribute small collections of their work, and that the invitation should not be confined to members only. In order to make the necessary arrangements and to fix the details of the committee, consisting of the following members, was appointed: Messrs. E. C. Elliott, Alfred Ellis, S. H. Fry, Martin Jacquette, Mr. H. C. Spink (president) and Mr. A. Mackie (hon. secretary) ex officio members.

The case was discussed of a number of complaints which had been received from private individuals in a certain country district that photographs had been obtained from them on the pretence of enlargements from them would be produced and delivered free, with the usual result, that neither the enlargement nor the return of the original photograph could be obtained. The hon. secretary was instructed to deal with the matter, and, if found necessary, instruct a local solicitor to bring a case before the magistrates at the Association's expense.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held on June 13, Mr. Teape in the chair. The members had

sure of welcoming him from his winter abroad the father of the ciation, Mr. A. L. Henderson, who, however, we regret to say, is not at present enjoying his usual good health. The members and all expressed the wish that an improvement would take place at an early date. Mr. Rapson stated that, in making varnish bleached lac, he had found trouble in getting all the lac to dissolve. Mr. Haddon said that this would be the case when the lac was old, as bleached lac would in time become insoluble, owing to the chemicals employed in bleaching it. Mr. Stretton stated that varnish makers found great trouble in dissolving bleached lac, owing to the water it contained, the greatest difficulty being experienced in getting it from water, and that unless this was done the varnish dried with what was known as a bloom. Mr. Teape said he had some mastic varnish which was unusable, owing to its showing a bloom about two days after use. The discussion turned upon the oil process of printing. Mr. Haddon could imagine any one using the process, as worked by M. Demachy, but he could obtain any other printing process. He thought that to properly use it a man must be a born artist, and in such a case it would get his results by easier and more direct methods. Mr. Stretton asked of what use would ortho plates be to any one who used the oil or gum process, as it was put before the photographic community, and Mr. Human said that it was of no use using colour-sensitive plates to get correct rendering, if one was going to destroy the rendering obtained by taking away or adding to by brushing. Mr. Stretton asked of the ortho plate v. ordinary for all classes of work, Mr. Human stated that Mr. Rapson had taken up his challenge in copying, the best subject to be the title-page of the "B.J." and he had proposed to annihilate Mr. Rapson upon this. Members are specially invited to attend the annual general meeting on Thursday, June 27, at the LONDON PHOTOGRAPHIC SOCIETY. On Monday last Mr. H. J. Teape, secretary of the Society of Colour Photographers, who had been specially from Stroud for the occasion, delivered his lecture "Three-Colour Photography" before the members of the above society. The lecturer's first experiment in this branch commenced twenty years ago, on observing the different appearances a camera had when viewed through the different tints of a stained window, and at that time he made a negative on an ordinary plate of a scarlet geranium, taken through a piece of pale red glass, the result showing in the resultant print showing as white; since that time his photographic interest had been mainly directed to colour photography.

Describing the apparatus he now used, Mr. Comley said that for portrait and still life studies any ordinary camera would do, but for landscape, and flower studies one having a repeat-back, carrying the three plates in parallel, was a necessity, and adjustment is so essential. Mr. Comley's own camera has a front of his own design, which he showed his audience. It is a shallow box, with interchangeable loose fronts, forming the lenses; a screen holder, similar to a lantern slide carrier, but with three openings for carrying the screens, slides through the box, and the screens close behind the lens rather than in front of the plate. He loads his slides and develops in complete darkness by "time development," using an ordinary metol and hydroquinone developer of 70 deg. for five minutes. Contrary to general opinion, negatives for three-colour work may be intensified or reduced, Mr. Comley using "Sanzol" for reduction and mercuric iodide for intensification, with excellent results. For his colour positives Mr. Comley uses stripping films, which are sensitised in potassium bichromate 3 per cent. for the blue to 10 per cent. for the red. The films may be dried as quickly as possible, for if the strong sensitiser is not removed it may re-crystallise if dried slowly. The tissue should be removed as soon after printing as possible, but if kept between damp blotting-paper it may keep as long as a week; but if it is not soon removed it will become insoluble within forty-eight hours. Mr. Comley prefers to use a packet of twelve pieces of stripping film to a packet of negatives. By this means he is enabled to select the depth of colour suitable for its fellows, for if, when adjusting the film on the yellow, one print should show too much blue, and the next has much yellow in the green produced, by changing them the correct colour may be obtained. In the superimposition of colours, should any particular colour be of smaller size than the others, he advises soaking the smaller in warm water, 80 deg. for 10 minutes, according to circumstances; this will cause it to swell to the size of the others, the celluloid base having the property

of swelling slightly in hot water. For cementing down the films he advises a solution of plain gelatine, without chrome alum, of the consistency of jelly, and he does not hesitate to thoroughly squeeze the films in contact; the smallest portion of gelatine is sufficient for adhesion, and gives more brilliant results. Mr. Comley expressed a decided preference for brilliant pictures to the more flat and subdued ones.

A number of colour prints by various processes, the work of members of the Society of Colour Photographers, was shown and commented on, also a selection of Mr. Comley's own work in portraiture, landscape, still life, etc., the fine quality of the work being much admired, both for its artistic and technical merit. A hearty vote of thanks was afterwards accorded Mr. Comley for his instructive lecture.

## Commercial & Legal Intelligence.

H. RHEINLANDER AND Co., LTD. (photographers, etc., London).—A £25 debenture, dated May 26, 1907, charged on the company's undertaking and property, present and future, including uncalled capital, has been registered. Holder: E. Law, Lindsley House, Osborn Road, Romford.

"BROMAR," LTD. (Photographic Dealers, London).—A trust deed, dated May 10, 1907, to secure £6,000 debentures, charged on the industrial establishment and premises in Rue St. Pierre Alost, Ghent (subject to a charge for 60,000 francs), and plant, implements, utensils, stock-in-trade thereat, Patent No. 5,948, of 1904, and foreign patents dependent thereon, the benefit of all improvements and further inventions discovered by J. Findlay and F. E. Fuller while in the employment of the company, and five sealed processes for the manufacture of plates and papers, etc., has been registered. Trustees: J. W. Davy, Castletown House, West Kensington; and R. D. Munro, 21, Lawrence Lane, E.C.

A "PROPERTY" EGG.—An amusing action concerning a property egg which, large as the witness box, occupied considerable space in the Brompton Court, was heard by Sir William Selje last week. Mr. William Henry Bunnett, photographic artist, of York Studios, Edith Road, West Kensington, sued Mr. E. Steer, the theatrical costumier, of Waterloo Road, who had supplied the egg, for breach of contract. According to plaintiff, the egg was quite useless for the purpose for which he wanted it, and was not at all the sort of thing defendant had contracted to make. It was to have been made of papier-maché, and pictures with ladies emerging from it were to have appeared in the daily papers at Easter time if it had arrived in time. A lady model had been engaged, and Mr. Bunnett expected to make from £15 to £20 on the deal. Defendant's story was to the effect that he found it was impossible to make the egg of papier-maché in the time given him, and in an interview plaintiff agreed to an alteration in the contract. The Judge finally found for the defendant, and related the story of the bishop and the egg. When the egg was delivered no doubt it was, like the bishop's egg, good in part.

A CITY BANKRUPTCY.—Richard Stanley Strauss, photographer, of Bowes Park, and lately carrying on business in Milk Street, Cheap-side, E.C., in the course of his public examination at the London Bankruptcy Court, before Mr. Registrar Linklater, stated that he had filed a statement of affairs showing gross liabilities amounting to £1,371 13s., and assets nil. The receiving order was made against him on the petition of a creditor, the act of bankruptcy being debtor's failure to comply with the requirements of a bankruptcy notice duly served upon him. He was an American citizen, and came to this country from Chicago in 1899 with a capital of £100 of his own. Upon his arrival here, he obtained employment with a firm of linen merchants, and subsequently he became a manufacturer's agent, trading with another, under the style of Strauss and Co. The business was unsuccessful, and in June, 1905, the partnership was dissolved. Since then he had been a photographer. He attributed his failure to loss on trading and costs of litigation. He had never failed before or made an arrangement with his creditors. The examination was ordered to be closed.

THEFT BY A CANVASSEER.—Arthur Thompson, giving his address as 22, Branstead Place, Leeds, and described as a canvasser, was charged,

on June 13, with stealing from the photographic studio of Messrs. M. E. Mitchell and Co., Harrogate, four gold pendants, of the value of 27s.

Evidence was given by Laura Barf, of 6, St. Mary's Avenue, an assistant at the studio. She stated that about six o'clock in the evening of the 11th inst., accused came into the shop and asked to see the manager. Witness left the shop and asked Mr. Mitchell to come, but he refused to see prisoner, who left the shop. After he had gone she missed the property. The pendants, two of which were gold, and two rolled gold, contained photographs. The property, which was worth 27s. without the pictures, was shown on a cushion in the shop, and she had seen it there before prisoner came in.

Bertie Bowles, an assistant to Henry Hardcastle, pawnbroker, of 34, Chapel Street, Harrogate, said that prisoner came into the shop at 7.40 p.m. and wanted to pledge two gold locketts. He said that he was in the trade, and wanted to raise his fare to get back to Leeds. Witness refused to believe his statement, and declined to take the locketts in pledge. When prisoner left the shop he followed him out, and informed a police officer, who was standing by, of what had occurred.

Prisoner pleaded guilty, and told the Bench that he had had something to drink, and gave way to a sudden temptation. He added that he was hard up, and wanted to get back to Leeds. He had a wife and three children, and if he was sent to prison the home would be broken up. He expressed his sorrow for what had happened, and asked the Bench to deal leniently with him. There were ten previous convictions recorded against prisoner, who was now sent to prison for three months.

#### NEW COMPANIES.

**J. GUNSTON.**—May 31, by Jordan and Sons, Ltd., 120, Chancery Lane, W.C. £500 (£1). To take over the business of a photographer carried on by J. Gunston at Bradford. No initial public issue. First directors (not less than three nor more than five): J. Gunston (permanent managing director), J. W. Booth, J. E. Longdin, and T. O'Keefe. £1. 60, Manningham Lane, Bradford.

**ILLUSTRATIONS.**—Capital £5,000 (£1). To acquire the business of wood, photo, and colour engravers, stereotypers, and illustrators by all processes, carried on by J. R. Burton, H. B. Burton, and W. H. Rake, at 99, Chapel Street, Salford, as the Burton-Rake Illustrating Company. No initial public issue. First directors (not less than two nor more than five): J. R. Burton, H. R. Burton, and W. H. Rake (all permanent). Qualification of permanent directors, £250; of others, £100. 99, Chapel Street, Salford.

## Dews and Notes.

**SOUTH ESSEX CAMERA CLUB.**—The fourth Continental excursion will start on August 10 for a fortnight in Belgium, conducted by the president (Mr. Walter D. Welford). The inclusive cost (no extras) is 26 17s. 6d., and all details may be obtained from 61, Mansfield Road, Ilford. The outing is open to all photographers and their friends. The following places are on the programme: Antwerp, Malines, Louvain, Brussels, Liege, Namur, Dinant, Ghent, Bruges, Ostend, L'Ecluse, Knocke, Heist, Blankenbergh, etc.

**THE PAGET PRIZE PLATE COMPETITION.**—The Paget Prize Plate Company announce a competition, in which all classes of photographers, from the professional to the beginner, are included, one class being devoted to those who have never won a prize before, and cash prizes amounting to £500 are offered. There are nine classes, and the prizes range in value from £50 to 10s. All prints and lantern slides sent in must be printed on Paget papers, or lantern plates from negatives taken on Paget plates, and must be accompanied by an entry form, duly filled up. These forms, together with full particulars of the competition, rules, etc., may be obtained from photographic dealers or direct from the Paget Company. The judges will be Messrs. A. C. Brookes, A. Horsley Hinton, and F. J. Mortimer, whose decision in all cases will be final. The competition

closes January 31, 1908, on or before which date all entries, marked "Competition," must reach the Paget Prize Plate Company, Ltd., Watford, Herts, and the results will be announced in the photographic press as soon as possible after the judging is completed.

A NEW "LORNA DOONE," edited and illustrated by Mr. and Mrs. H. Snowden Ward, is promised for the autumn by Messrs. Sampson Low, Marston, and Co., Ltd., Mr. Blackmore's own publishers. The volume will contain the whole of the West Country classic, with another less-known "Doone" story from Mr. Blackmore's pen, as well as a lengthy introduction, and copious notes. The added matter will include the legends of the Doones and other characters, an inquiry into their actual existence, notes on Mr. Blackmore's personal knowledge of the districts described, and some interesting unpublished evidence as to the real originals of the Doone Valley. The illustrations will represent all the principal places mentioned in the story, the scenes in and around Oare, Tom Faggus' forge, Mr. Huckabach's shop, Lanacre Bridge, with its memories of Jeremy Stickles' escape from the Doones, the place where Lorna's mother was buried, great Dunkery beacon, and many another landmark in the story. The editors ask that anyone who can throw original light upon the history or early traditions of the Doones, Ridds, etc., their historical existence, or other points pertinent to the story will communicate with them, at Hadlow, Kent.

"Lux," edited by Mr. J. R. A. Schouten, devotes no less than six pages of its current issue to an illustrated article dealing with the proceedings of the forthcoming meeting of the Photographic Convention at Hereford.

THE PHOTOGRAPHIC OPERATOR who, after sending a telegram to sister saying he was going to drown himself, disappeared from hotel at Bath, has been found in Bristol. He has been suffering from loss of memory.

THE "MAGPIE" of our contemporary, the "Amateur Photographer," has been wading in deep waters, much too deep for foothold, poor bird, and now, with his plumage bedraggled, he is striving to reach dry land. It would appear that, with a commendable desire to acquire much needed scientific information, he has been attending meetings of the Royal Photographic Society and has attempted to assimilate a mental diet that is beyond digestive powers. In his latest effusion he prattles with childlike innocence of the "Perkins" phenomenon, with which he evidently desires to be thought on terms of intimate familiarity. Perhaps he will now inform his readers who "Perkins" is, where he lives when he is at home, where he discovered his phenomenon, and what it has to do with dark-room safe-lights. Is it possible that omniscient "Magpie" imperfectly caught the sound of the name Purkinje, and promptly seized upon the nearest English phonetic resemblance to it to give verisimilitude to the bald and unconvincing narrative he had to tell? The occurrence of the same substitution at another place prevents us from assuming the comfortable explanation of a compositor's error.

**ESSEX PHOTOGRAPHIC AND PICTORIAL SURVEY.**—The second annual meeting of the Photographic Survey and an ordinary meeting (25th) of the Essex Field Club were held on Saturday at Kelvedon. The programme carried out was a most interesting one; from Kelvedon the party drove to Little Coggleshall, where the ancient abbey chapel were viewed. Thence they proceeded to Coggleshall, several other ancient buildings and interesting objects were inspected, notably the church of St. Peter ad Vincula and the lace and velvet workers. Luncheon was served at the Chapel Hotel, Sir Benjamin Stone, M.P., president of the National Photographic Record Association, presiding. The party then drove back to Kelvedon, St. Mary's Church was inspected after tea at the vicarage, at invitation of the vicar, the Rev. E. F. Hay. Sir Benjamin Stone, during the rambles related his experiences in his travels on photographic expeditions. More than once people whom he had photographed threatened to kill him. When he was in China a crowd of people, of whom he had obtained an excellent photograph, became so excited that he asked his interpreter what was the matter. It was told that he had taken their spirit from them. When he had taken nothing, the interpreter asked, "You have got the likeness, how can you say you have taken nothing?" The people became so riotous that he had to bribe them to ensure his safe

opening to be in Brazil during a revolution he was able to see a Governor was deposed. The person aspiring to be Governor entered a disturbance, and then made terms with the general of military forces to get the Governor out of the palace. To accomplish this the cannon were fired upon that place, but these firing operations were suspended when a photographer appeared upon the scene. The officers posed at the cannon, and those in the palace who had not been killed came to the balconies. After the new Governor gained possession of the palace the military general sent round word that he had made a mistake on the previous day, and forthwith proceeded to drive the gentleman out of the palace too, which was naturally very much damaged.

\* We do not undertake responsibility for the opinions expressed by our correspondents.

### REFLEX CAMERAS.

To the Editors.

Gentlemen,—I, with many other pressmen, have read with much interest the comments recently made in your columns with respect to reflex cameras, and think your exhibition is the right thing. In realising the many advantages the reflex cameras offer, especially perhaps to illustrations, your article will doubtless refer to drawbacks there may be.

The type appears to stand pre-eminent, but only when made by thoroughly experienced people, who put the very best work into their productions, and turn out what is practically a perfect, though necessarily expensive, camera.

My experience has been rather unfortunate. I purchased a somewhat low-priced reflex, and have had many failures, some, at least, I think due to defects of the camera. The mirror goes up quietly enough, but the shutter (focal-plane) does not come down with the same pressure, but has almost to be jerked down, with disastrous results. That, I believe, is due to the actuating mechanism being faulty, inasmuch as mirror and shutter do not work together.

The focussing is splendid, but it is very annoying to be unable to get the shutter off till after the "subject" has gone! That sort of thing is disastrous to one's reputation, for when failure has to be reported, whatever the excuse, there is a serious "going down" in the estimation of those who send out the order.

Seeing the great success of this exhibition, though confined to one type of camera, would it not be possible to arrange a really representative exhibition of all belonging to photography, much as is done at the Stanley Show in the case of cycles? What a lovely exhibition it could have!—Yours, etc., G. J. WILKINSON.

"Lancet" and "Echo" Office, Lincoln.

### COLOUR PRINTS AND TRANSPARENCIES.

To the Editors.

Gentlemen,—It may be interesting to some photographers to know how beautiful coloured prints or lantern slides can be made from colour negatives in the following manner:—Take, for instance, a negative of some flower study, in which the only two colours necessary are yellow and green. (The enclosed print and slide are of a rose growing in its natural state, and the other print laburnum.) Making the transparency, a piece of blue carbon tissue is first exposed under the negative, this is squeezed on a gelatinised glass, washed and finished, as is usual, in making carbon lantern slides. A piece of yellow glass is now put behind this transparency and two are held up to the light, it will be seen that the two colours combine and give a result marvellously true to nature. In the first instance it will probably be found that the yellow of the glass is

not correct, or is either too dark or too light. In this case get a piece of clear sheet gelatine and dye it in some suitable dye—e.g., naphthol yellow or tartrazine, or a mixture of both.

When the correct colour is obtained the slide is either mounted with the yellow cover glass or the dyed gelatine is sandwiched between an ordinary cover glass and the transparency.

In making prints, a piece of paper must be dyed in the above dye till the requisite colour is obtained, then be coated with a gelatine solution, and used as the final support.

#### GELATINE SOLUTION.

Gelatine .....	32 grs.
Distilled water .....	2 ozs.

Soak for four hours; dissolve by aid of a water bath.

Chrome alum .....	1.2 grs.
Distilled water .....	.4 ozs.

Dissolve and add to the gelatine. Coat the final support with a fairly stiff hog-hair brush, and allow to dry.

The enclosed prints were made on marine blue tissue, and the dye used for staining made of equal parts of solutions of naphthol yellow and tartrazine.

These colours would obviously be only suitable when the resulting colours required are green and yellow.

For blue flowers and green leaves the tissue would have to be yellow, and the cover glass, gelatine, or paper, blue. In the case of still life studies requiring only purple and blue, or orange and yellow, the tissues would have to be red in each case, and the cover glass, gelatine, or paper, blue and yellow respectively.

I came across this method quite accidentally, simply by holding a blue carbon transparency up to the light of a dark room lamp having a yellow glass in it. I should very much like to know if this method has ever been used before, and for the same purpose.—Yours, etc., THOS. J. FAIRFIELD.

Drury Lane, Solihull.

June 6, 1907.

[The lantern slides and prints sent to us by our correspondent are very effective, and at a first glance might pass for examples of the three-colour process. We believe a similar process has been recommended for transparency work in conjunction with the methods of chemical toning.—Eds., "B. J."]

### THE EFFICIENCY OF IRIS SHUTTERS.

To the Editors.

Gentlemen,—In Mr Anderson's interesting articles on the "Efficiency of Modern Shutters," he seems to have rather jumped at conclusions with regard to the iris shutter, that is, the central opening shutter with circular aperture. If the full aperture of the shutter is equal to that of the lens, and the speed of the shutter is constant, the efficiency is  $\frac{1}{2}$ , not  $\frac{1}{4}$ , as he states. I do not follow the process of reasoning which leads him to assume (p. 405) that the efficiency can be ascertained from the average size of the aperture. The only reliable method is to ascertain the actual duration of exposure at different parts of the aperture and then arrive at the total by a process of integration. If a constant speed is assumed this is easily done by geometry. In this case the ideal effective exposure can be represented by the cubic capacity of a cylinder equal in base area to the aperture, and in height to the duration of the exposure. With the iris shutter the efficient exposure is then equal to the cubic capacity of a cone of the same height and base, which, of course, will have one-third the capacity of the cylinder. In "Photography Annual" for 1896 I gave full particulars of this geometric method of calculating efficiency, and also a number of comparative results.

Mr. Anderson's conclusions are likely to give readers a very poor opinion of the iris shutter as regards efficiency, and he has not carried his investigations far enough to realise its advantages over the blind or direct movement shutter, which may really have a much lower efficiency. Assume that with either shutter the shutter aperture is the same diameter as the full aperture of the lens, and that all apertures are circular, then, if the full aperture is  $f/8$ , and the duration of the exposure one second, the efficient exposure of the direct movement shutter is  $\frac{1}{4}$  second, and with the iris shutter  $\frac{1}{8}$  second. If now we stop down the lens the efficient exposure remains exactly

the same with the direct movement shutter, but increases rapidly with the central shutter. At  $f/16$  it has increased to  $\frac{3}{4}$  sec., and at  $f/32$  to 5-6 sec. with the latter shutter, while it still remains  $\frac{1}{2}$  second with the direct movement shutter. With  $f/64$  the efficiency of the central opening shutter is very high, being 11-12, and the efficient exposure is 11-12 second if 1 second is the total duration. In the same conditions with the direct movement shutter the efficiency is 8-9, but the efficient exposure is still  $\frac{1}{2}$  second. The difference is due to the fact that with the latter shutter the actual duration of the exposure diminishes as the stop is reduced, while with the central opening shutter the duration is unaffected by the size of the aperture. Of course, the question is practically affected by the fact that the blind aperture is always square. This adds about 27 per cent. to the efficient exposure given above, and increases the  $\frac{1}{2}$  sec. efficient exposure to one of .63 sec., which is still below the efficient exposures given with the central shutter at apertures from  $f/16$  down. One more point in which the iris shutter scores is this. The whole plate is affected during the whole of the exposure, whereas with the other shutter, at the moment of opening, and just before final closing, only a part of the plate is affected. This tends to lower the general efficiency.

There is, of course, a fundamental defect in all these methods of estimating efficiency. We have to assume uniform speed, whereas the speed never is uniform. This also affects Mr. Anderson's tests, seeing that he only actually measures the total time, and the time during which the shutter remains open, and simply estimates the efficiency during the opening and closing. It is probable, however, that the assumption of a uniform speed in many cases gives a result that is not very far out, and the error is hardly likely to be so great as that produced by Mr. Anderson's mistaken estimate of  $\frac{1}{4}$  instead of  $\frac{1}{2}$  for the efficiency.

His test would, of course, break down in cases where the shutter opening is smaller than the lens aperture, as in the case of the highest speed of the Celerex shutter, and in that of a few other shutters.

C. WELBORNE PIPER.

#### A WAVE OF ORTHOCHROMATISM.

To the Editors.

Gentlemen,—It is fair to you to say that the No. 1 preferred by you was taken through a screen, though really in this case I cannot quite understand your choice for the whole subject. Although it is not a distant one, there is to my mind a decided loss of atmospheric effect. I should think most workers would be obliged to Mr. Thomas for his clear putting of the principles to be borne in mind in working with colour-sensitive plates in your issue of June 7.

PROFESSIONAL.

[We stated that there was little difference in the two prints; but the subject having a bed of flowers as the principal object in the foreground, we attached importance to the better rendering of the greens in this part of the picture. It is true, as our correspondent says, that there is a loss of atmosphere in the distance, but as that distance was a row of villas, and only about 50 yards away, we could not see that it mattered much.—Eds. "B.J."]

#### FLUORESCENCE IN OPTICAL SENSITISING.

To the Editors.

Gentlemen,—With regard to Mr. E. J. Wall's remarks on Dr. Stark's paper, from the "Physikalische Zeitschrift," may I be permitted to point out that Mr. Wall's experiment does not appear to me to be comparable with that described by Dr. Stark?

Mr. Wall obtained, by the use of water in a test tube, arranged so that the meniscus of the liquid is exactly opposite the middle of the slit, a continuous stripe from sunlight or incandescent gaslight, which he ascribes, no doubt rightly, to the prismatic effect of the meniscus edge. But Stark, in his experiment, was not using a light source giving a continuous spectrum, but a mercury vapour lamp giving a line spectrum, and the prismatic effect of the meniscus could only produce from this a bright section of the line spectrum, and not a continuous stripe, which could only be ascribed to fluorescence.

The same argument applies to Mr. Wall's further remarks with

regard to light reflected laterally by small particles. The reflecting power of small particles depends upon their selective reflection for the shorter wave-lengths, and if they possess the power of transforming monochromatic light into light of any other wave-lengths, they must be said to be fluorescent, though, so far as I know, this power has never been ascribed to small particles as such.—I remain, yours faithfully,

C. E. KENNETH MEES.

## Answers to Correspondents.

- \* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.
- \* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- \* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington Street, Strand, London, W.C.
- \* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

#### PHOTOGRAPHS REGISTERED:—

- F. G. Fraser, Greig Street Post Office, Inverness. Three Photographs of the Rev. Murdoch Mackenzie.
- J. Mason, 20, Corporation Road, Newport, Mon. Photograph of the Prince of Wales taken at Newport, June 8, in Procession.
- S. Edwards, 22, St. John's Road, Tunbridge Wells, Kent. Photograph from an Old Engraving, "Procession of Lady Godiva at Coventry Fair."
- J. T. Turner, 40, Bath Street, Tunstall, Staffs. Photograph of the Interior of the Jubilee Chapel, Tunstall, with Audiences. Centenary Mass Meeting.
- F. Sadler, 41, Ridley Street, Birkenhead. Photograph of Leasowe Lighthouse and Camp. Photograph entitled, "Cockles."
- G. W. Davies, 49, Victoria Road, Ebbw Vale. Photograph of Steeple of Christ Church, Ebbw Vale.
- W. H. Hewitt, Stables Road, Dronfield, Derbyshire, near Sheffield. Photograph of Group, Fancy Dress Cricket Match, Dronfield, June 8.
- J. W. ELLIS.—All the transparencies you send are far too thin and flat. The more brilliant carbon transparency would have been about right had you used red chalk tissue instead of the brown. Transparencies for enlarging require to be soft, but not such thin lifeless things as you have made. Try using a slow ordinary plate, expose to artificial light, and use pyrocatechine or rodinal for development. It is advisable to back the plates on which the transparencies are made. The white spots are finger marks.
- STUDIO.—Will you kindly let me know if, in your opinion, there would be sufficient and a practical light in a studio, sketch enclosed, for professional purposes? The window is north light, unobstructed.—S. S.
- You can, of course, take portraits in the room, but we should say that it is by no means adapted for general professional purposes. If you utilise it we would suggest that the size of the window be increased two or three feet towards the camera end, so that you can curtain off some of the light at the background end, otherwise the direct side light will be too strong; and if you do that with the window as it now is, there will be little light to work with. The studio is very short for professional work.
- J. E. H.—Any photographic dealer or bookseller, or from the publishers, 52, Long Acre, London, W.C.
- PRESS.—(1) The best answer to this question is to advise you to buy a copy of "Photography for the Press" (Dawbarn and

ard, 1s.). (2) From 30s. a week. Expenses are, of course, paid. Usually not.

QUERY.—I have in my possession a French cabinet portrait lens, in. focus, by Hermagis; number on lens, 9,304; no stops are provided with the instrument, or any slot to insert any. I did on giving it a careful test that it will not cover a cabinet picture, as you will notice by the two enclosed rough prints. Could I have stops adjusted to the lens to improve the sharpness, it does not answer my purpose for everyday photography as remains? Do you know if the lens has any commercial value attached to it? Can you suggest why no stops were adjusted to the instrument when new, as one finds stops are placed in pretty well every kind of maker's lenses?—F. BAILEY.

It is pretty evident the instrument is not a cabinet lens. It is the old form of portrait lens, with a very round field, and was probably made before the cabinet portrait was introduced. These early lenses were not fitted with central stops. Properly made cabinet lenses are specially corrected for flatness of field, and are always fitted with stops. You can, of course, have stops fitted, which will improve it, if you think the instrument is worth the outlay. The lens has little commercial value nowadays.

PRINTING PHOTOGRAPHS.—I am a process artist, and have some photographs to retouch in colour, which upon completion must show no signs of having been worked on, and look as before unretouched, and I should feel obliged if you will inform me, through the medium of your valuable paper, of some way of printing the photographs, after working up, to give a brilliant result.—PROCESS.

We should say the best thing you can do is to get a set of colours specially prepared for tinting pictures that are now used by all the dealers. These colours, or rather dyes, are quite transparent and easily applied, if used according to the instructions issued with them. They do not materially interfere with gloss.

GROUND.—I wish to make a 12 x 8 distemper background on a wall. Could you give me any instructions as to the making of it? What colour distemper would you recommend for it?—H. S.

Space is far too limited in this column to give such details as would be of any practical service to you in making backgrounds. You refer to page 82, of our issue of February 1 last, you will find full working details for making distemper backgrounds. On page 155 of the issue of March 1 is another practical article on making backgrounds by the powder process, which you will do well to read.

RIGHT.—I have a photograph of a Pierrot troupe and audience, taken on an open space of ground, part of which is fenced in, and which they pay rent. My photograph, which I am publishing in postcards, was taken from the top of an electric car, which was on the main road close by. They have written to one of my agents asking him to discontinue selling them, as they say I reserve the right to sell postcards of their stand. If he does not stop the sale of them they threaten to take further proceedings. What I want to know is, if they can proceed against me if he does not stop selling the card, and if they can proceed against me from publishing the same. As it was taken from one of the main thoroughfares, I do not see that they can do anything.—PRO.

THE PARTIES HAVE NO POWER whatever to restrain you, unless the card or photograph is of such a nature that it can be held to be harmful to their business as entertainers or prejudicial to them individually.

PHOTOGRAPHY IN CANADA.—I have been in business, as you will see, for some time, but have made very little progress, and this is very discouraging. Could you, through your valuable paper, give me any idea of the prospects of photography in Canada, and what part do you recommend? I am used to good middle-class work, being used to finishing my own work throughout. I have a good stock of materials, and would I have any difficulty in getting the smaller goods with me, or should you advise selling and should I have much difficulty in buying apparatus out

there, and about the price? I may muster £150 to start me with. Do you think, on these conditions, I should be doing wise in going out?—ANXIOUS.

We can only say that, as a whole, prospects in Canada are very bright, and that those who are prepared to rough it if necessary are likely to settle down to a good position before long. We advise you to write to the "St. Louis and Canadian Photographer," 3,210, Locust Street, St. Louis, from which you will be able to obtain some particulars of conditions in Canada.

BRADFORD.—The particular card we judge to be by lithography. There are really no books in English on multi-colour litho, though several in German.

SUNDAY TRADING.—Will you be so kind as to forward me, as soon as possible, the "B.J." with the account in of the magistrate's decision of photographers opening on Sundays at Blackpool? The police have been to my place at the above address and forbid me opening on Sundays, they said, under a penalty of £5. I have just taken these premises for three years, but unless I open on Sundays the place is useless, as the trade in the week is little or nothing, but very good on Sundays. Your very kind information on this will greatly oblige, as to whether they can shut me up or fine me so heavily.—A. D.

Under an old Act, passed in the reign of Charles II., it is illegal for anyone to carry on his business on the Sunday. This antiquated law is now but seldom put in force, and, where it is, it is chiefly in country places. However, the Act is still on the Statute Book, and can be enforced. The police have told you wrong about the £5 penalty. The heaviest fine that can be inflicted is 5s. A shopkeeper in High Wycombe has been summoned and fined between two and three hundred times, yet he keeps his shop open every Sunday.

DOUBTFUL VALIDITY.—Would you be so good as to give me your opinion of the following in the "Journal"? I am a manager for a photographer here, and two years ago he got me to sign an agreement as follows: "That I would not start in business on my own account, or within twenty miles of —, or enter into partnership, nor take any shares in any photographic business in —, or within the radius mentioned." This evening he gave me a week's notice, and says if I work for another photographer in — he will commence proceedings against me. I would like you to say if you think he can stop me working for another. I am under the impression he cannot. I should be glad if you would give me your answer.—DOUBTFUL.

Unless we saw a copy of the agreement or knew the conditions under which it is made we cannot express any opinion upon it. According to what you say, it seems very one-sided, and it is a question whether it would hold good in equity. Twenty miles seems to be rather a wide radius, and might be looked upon in a court of law as an undue restriction of trade, in which case the thing would become invalid. Your best way will be to consult a solicitor and show him the agreement; he will then be able to advise you in the matter.

MIDGETS.—I would be very pleased if you would let me know how I could number midgets when taking them out of doors, as on the beach, where a numbering arrangement cannot be fixed up.—GLASGOW.

You buy an apparatus in which the numbering is all done in the camera. See page 1,371 of the 1907 "Almanac."

A STUDIO QUERY.—I covered the top light of studio with tissue paper three weeks ago, but now it has turned a deep yellow. I have never found tissue paper to act like this before. Will you kindly let me know the cause of this; or, if the paper is impure, the address where I can buy the best quality? Failing this, would you give me a formula for painting on the glass which would have the same effect as ground glass, but could be quickly rubbed off in the winter?—TISSUE.

Certainly an impure paper is the cause of the yellowing. It is a common feature of a low-quality paper, but you should have no difficulty in getting a good, pure paper which will not behave in this way. To obscure the glass, a very good plan is to apply fairly thick starch paste. This preparation will wash off, of

course, in the wet, and should, therefore, be applied on the inside of the studio.

**SHIPPING PHOTOGRAPHER.**—I am a professional photographer, and am anxious to get a berth if possible on board one of the Atlantic liners as photographer. I notice the "Adriatic" and other ships have a photographic department. Could you assist me by informing me the address of the best offices, and, if possible, name of the chief to write to?—ATLANTIC.

We can only refer you to the managers of the various shipping companies, whose addresses you will see in almost any of the leading daily papers, or in publications such as the "Shipping Gazette," published by Spottiswoode and Co., Ltd., 54, Gracechurch Street, E.C.; or the "Shipping World," published by the "Shipping World," Ltd., Effingham House, Arundel Street, W.C.

**SULPHIDE TONING.**—I have experienced some peculiar results in developing plates with a strong solution, as follows:—

Hydroquinone .....	122 grains.
Metol .....	46 "
Sodium sulphite (crystals) .....	920 "
Sodium carbonate (crystals) .....	1,381 "
Potassium bromide .....	76 "
Distilled water .....	35 oz.

Exposing on a subject which is very difficult to judge for exposure I am unable to make any density, also, on continuing development, to obtain it, the image, which on first appearance is good, almost disappears from the plate. The clearest result is obtained by stopping development quite early, but the fixed plate is then extremely thin.—F. W.

We must say that your experience is most exceptional, and we can see nothing in the formula as you state it to account for the facts, assuming, that is, that the chemicals are of proper purity. The presence of hypo in the developer would, we think, give rise to something of the kind you have experienced, and, if you must use the formula you give, we should advise you to make it up with the chemicals of undoubted purity.

**SULPHIDE TONING.**—(1) I had a bromide print enlargement developed with metol-quinol. After fixed and washed for forty minutes I bleached in ferricyanide of potash, 20 grs.; potash. bromide, 20 grs.; water, 20 ozs.; well rinsed and put in 100 grs., 20 ozs. water, sulphide solution, but it would not tone, nor would the image come back still bleached. Is there any remedy, or can I have it returned to black and white again? (2) I find every toning, as above formula, gives rather brown tone than sepia. Is it possible to have darker colour with sulphide, using some other chemicals?—L. M.

(1) As we understand your query, we should say that the use of an ordinary developer, such as metol hydroquinone, will bring back the picture with very little modification in colour. We have heard of similar cases of refusal to darken in the sulphide solution, but have never been able to discover a remedy. The difficulty appears to be due in some cases to the paper, and a change in the brand has put matters right. (2) There are, as you say, variations in the tones given by the sulphide process, and they are due, we think, almost as much to the papers on which they are used, as to the toning formulae. One formula which we have used to get very good dark tones consists simply in the use of weak bromide water as a bleaching agent. The objection to this solution is the irritating vapour which escapes from it, but in other respects it is a very quick and powerful bleacher, and the prints need be simply rinsed for an instant only under the tap before placing it in the sulphide solution.

**FREE SITTINGS.**—Some time ago I invited a gentleman of note and popularity for a sitting. I presented him with a few copies free; later on he ordered some photographs, for which I charged the usual price. With his permission I then published some postcards, and also sold a number of photographs. Last week I noticed that the photograph has been published in a weekly paper, and a supplement print presented with each copy. I have written to the publishers to say that the copyright is my own, and that they had no right to publish same without my permission. This is just a week ago, and, so far, had no reply whatever. What I wish to know is, can I claim any damages, and what steps should I take?—A. G.

The copyright is certainly yours, but, in the absence of a

written assignment of it to you, it will be difficult for you to prove your proprietorship. It is usual to obtain such an assignment from a sitter at the time. You can, if you like, register the photograph now and take action in respect of sales of publication subsequent to your registration; but, on the whole, we should advise you to give up the idea. Evidently you have not read the very clear notes on this matter which appear in the "Almanac" for 1906, and have only yourself to blame for the position you are in.

**TONING WITHOUT GOLD.**—Will you kindly give me a formula for quickly toning small batches of P.O.P. postcards? Absolute permanency not essential, speed of execution, with a minimum of washings, desirable. I think I saw a toning and fixing solution without gold given in the "Journal," but being away from home cannot lay my hand on it. If you can help me I shall be thankful.—NEMO.

The process appeared in "Photographic Scraps" for November 1904, p. 180. If you write to the Ilford Company, Ilford, E., doubt you can obtain a copy. An abstract appears on page 6 of the "Almanac," 1906.

**J. CLAPHAM.**—Fairly full exposure and restrained developer, preferably pyro, hydroquinone, or glycin. It is difficult to get absolute black and white.

**GRIFFIN'S RENDEZVOUS.**—Messrs. John J. Griffin and Sons, Ltd., invite all interested in photography to visit their exhibition gallery in Kingsway, London, W.C., where from time to time examples of pictorial work will be on view. The present collection includes portraits, landscape, and seascape studies, by Worsley Benison, oil paintings by G. E. H. Rawlins, and portrait studies by Herr R. Dührkoop, Hamburg. In conjunction with each exhibition practical demonstrations will be given, as well as a series of pictures, and the latest forms of apparatus and materials will also be on view.

#### LIGHTNING PHOTOGRAPHY.

(A Burglar's Protest.)

I sees at Deal, the other day,

A rummy thing occur,

Which in our trade—the trooth ter say—

As made no end of stir.

A lightnin' flash, wot charnced ter pass,

A vase snapshotted cleer,

And print it on a looking glass

As stood convenient nere.

Now, since 'twas but a vase, yer see,

The consikwence was slight;

But think, if it had photo'd me,

While burglin' of a nite!

Which, wot with finger-prints, says I,

We've risks enuff and more.

Without them helements on 'igh

A-shuvvin' in their hoar.

From "Truth."

## SUMMARY.

Reflex Camera Exhibition.—This continues to attract an in- number of visitors. The average attendance per diem ast week has been forty.

Legal use of negatives and photographs, which deals, of ith the all-important point of copyright, is dealt with y, and a policy of not killing the goose that lays the golden dvocated. (P. 479.)

Efficiency of dark-room filters is fully described by Dr. Mees Baker, and the relation of visual intensity, safety, and shown. (P. 481.)

st of a series of useful articles on the collodion process W. Foxlee appears. (P. 485.)

lson K. Cherrill describes a distinctly novel reflex camera, specially intended for the use of artists. (P. 484.)

ct of Photography is an amusing extract from "Truth," eaks very plainly on the subject. (P. 486.)

s only to be expected, the oil process is attracting con- atention. (P. 488.)

dy for platinum printers' catarrh is given, and strongly ded, by an American writer. (P. 477.)

thur Payne has written a new work on wet collodion, reviewed on p. 489.

amount of commercial and legal intelligence appears this duding an interesting copyright case. (P. 491.)

ggestions are made with regard to improving the useful- reflex cameras. (P. 494.)

apman Jones discusses the efficiency of the iris shutter.

## The Decline of Stereoscopic Work.

That the decline in stereoscopic work is general cannot be denied, notwithstanding the fact that amongst a few amateurs it is still enthusiastically pursued. Various reasons have been advanced for this falling off. By some it has been ascribed to the extra trouble involved in making stereo prints. By others to the want of clearly defined rules of working, and by others again, to the wave of pictorialism which has swept over us. With regard to this last reason it must be admitted that the want of interest in stereoscopy was in evidence long before pictorial photography, as we now know it, was thought of. One of the chief reasons we believe to lie in the necessity of using a stereoscope so that only one person at a time can see the results.

## EX CATHEDRA.

That the decline in stereoscopic work is general cannot be denied, notwithstanding the fact that amongst a few amateurs it is still enthusiastically pursued. Various reasons have been advanced for this falling off. By some it has been ascribed to the extra trouble involved in making stereo prints. By others to the want of clearly defined rules of working, and by others again, to the wave of pictorialism which has swept over us. With regard to this last reason it must be admitted that the want of interest in stereoscopy was in evidence long before pictorial photography, as we now know it, was thought of. One of the chief reasons we believe to lie in the necessity of using a stereoscope so that only one person at a time can see the results.

\* \* \*

## New Ideas in Stereoscopy.

Suggestions have been made at different times to obviate the necessity of transposing the prints. We have had, for instance, the method of using mirrors in front of the lenses or mirrors behind them. The objection to these has, of course, been the fact that any such arrangement adds not only to the weight, but the expense of the apparatus, and, further, such mirrors to be efficient must be silvered on the surface. Assuming that the ordinary form of stereoscopic camera be used then various instruments have been devised and patented to obviate the necessity of transposing the prints; but not one has come into general use. In the current "Zeitschrift für Wissenschaftliche Photographie" Herr Fricke suggests that instead of using the ordinary ocular a reversing system as used in the microscope or telescope should be used and the prints mounted upside down. The production of eyepieces of this type of sufficient size should not present any optical difficulty, but they would presumably be somewhat expensive. In order to obtain transposed negatives the author suggests that Porro prisms, as so much used nowadays for binoculars, should be fitted either behind or between the lenses. At first sight the objection to these is the price, and to the second suggestion the field of view would be considerably reduced.

\* \* \*

## Developing Panchromatic Plates.

In the discussion which followed Dr. Mees' and Mr. Baker's paper at the R.P.S., which appears on another page, the point was raised as to loss of colour-sensitiveness of the plates after immersion in the developer, and reference was made to experiments by Lüppo-Cramer and Valenta which certainly bore out this statement. The matter has, however, been satisfactorily settled by Dr. Mees and Mr. Baker, who have communicated to the "Photographic Journal" the results of some special tests which they have

made to determine the point. The conclusion they have come to is that using metol-hydroquinone, ferrous oxalate, and hydroquinone and caustic potash the plate had about one-quarter of the normal sensitiveness, but "that the effect of soaking a plate in a developer is insufficient to protect a panchromatic plate if it be incautiously exposed to red light."

#### Examining the Plate during Development.

That examination of a plate during development can have absolutely no effect upon its good qualities is a fact which probably will not be denied by any one. Even if one adopts the factorial development system as devised by Mr. Watkins it is applicable obviously only to those plates which are not panchromatic. The time development system, that is, development with a solution of constant composition at a constant temperature for a given time, completely solves the difficulty, provided, as some one has said, you have somebody to call out the time or a recording clock. When one is forced to use a watch, however, there should not be the slightest difficulty in temporarily covering the dish up to see the watch face, and one may use for this a light-tight box, or, obviously, if one works some distance from the light, a sheet of stained glass of a colour complementary to that of the dark-room light will at once produce practical if not theoretical darkness over the plate.

#### Sunspots.

The generally accepted opinion as to the cause of these is that an opening in the photosphere enables us to see the relatively dark surface of the solar body itself. This being so it was natural to assume that the sunspots were due to an eruption or irruption of gaseous matter forcing its way through the brilliant vapours, and confirmation of this view could be obtained by proving the motion of the Fraunhofer lines in the line of sight. Professors Hale and Adams have recently dealt with this subject in the "Astrophysical Journal," and state that the importance of the question of the motion in the line of sight of the spot vapours as bearing on any theory of spot structure, is, of course, very great, and has been kept in mind in the investigation of the observational material. In the method which they have adopted of photographing spot spectra it is necessary to make the exposures on spot and disc separately, occulting one while the other is being photographed. For this purpose an occulting bar is moved across the slit by means of a rack and pinion, as in most stellar spectrographs. Accordingly, the danger of errors arising from instrumental sources should not be great.

#### Photographs of Spot Line Displacement.

The study of the plates (continued Professors Hale and Adams) has led to the conclusion that there is, as a rule, very little motion in spot umbrae. Out of eighty plates of eleven spots only two gave any reasonably certain displacements of the spot lines, and even in these two cases the values were close to the limit of accuracy of the measures. In both instances the motion was directed downward, and amounted to about 0.2 km. a second. In one case, moreover, the motion was certainly temporary, since plates of the same spot taken on the following day gave no displacements whatever. The general conclusion, then, seems to be justified that the vapours forming the umbra of a well-developed spot are normally nearly at rest, with perhaps some presumption of a slow downward drift. This result is in agreement with that found by Mitchell from the study of a large number of spots during 1904-5. He says:—"Line-shifts

in the spot spectrum, with the exception of those due to hydrogen, are very rare."

#### Platinum Printers' Catarrh.

Two years ago some discussion was raised in our columns on the above, and therefore the following suggestion from a writer in one of our American contemporaries may be useful. He states that he has just recovered from a severe and prolonged attack, and found his remedy rapid and efficacious, and apparently he is now immune. The remedy is common salt. "To heal the sores on the hands put half a gallon of hot water in a basin, and dissolve in it about two large tablespoonfuls of common salt; immerse the hands and wrists in this, and keep them in it for half an hour. Rinse off the salt water and dry the hands. Do this twice a day—in the morning before commencing work, and in the evening when quitting. The sores rapidly heal. To cure the nasal catarrh, make a weak solution of salt water, a small teaspoonful of salt (or a quantity as feels agreeable to the nose) to a pint of water heated to about the temperature of the human body, sniff a portion of it into the nose twice a day; or use a nasal douche. Bathe the eyes in this also, if they are affected. If a steady worker in platinum papers, these solutions once a day as a preventive."

#### The Lighting of Pictures.

In the hanging of pictures photographers often seem to neglect a consideration that is never ignored by painters—that is, the direction in which the light falls on the picture. It may be taken as a rule that all pictures appear at their best when they are lighted from the same direction as their subjects. As it is impossible to observe this rule with a large number of pictures in a gallery the compromise of top-lighting is resorted to, but in private rooms there is seldom any great difficulty in arranging pictures so that they shall be properly illuminated. There seems, however, to be an idea that top-lighting is the ideal, probably just because it is the only possible form of lighting that can be adopted in picture galleries. This is entirely a mistake. It is suitable to some subjects in which the lighting is naturally from the top, as in open landscapes and seascapes, but in the majority of cases sidelight is a feature of the picture, the picture then appears at its best when lighted from the side. We have actually heard this correct method of lighting described as tricky and theatrical, but such an absurd idea is not countenanced by painters, who are fully aware of the importance of viewing the picture under natural conditions of lighting. The ideal place for a picture is in the studio in the position occupied by the subject. If it does not appear at its best in this position, there is certainly something wrong with it. This is the painter's test, and it is an equally useful and effective one for photographers. It naturally follows that the same conditions of lighting should be as far as possible preserved when the picture is permanently hung, if it is to be shown to the best advantage.

#### Dr. Wells and Darwin.

A short time ago we referred to Dr. Wells's essays on single vision as valuable to the student interested in visual optics. A friend who has been studying Dr. Wells's collected papers published in 1818 now draws our attention to the fact that the last paper in the volume is an exposition of Darwinian theories of natural selection and of the survival of the fittest. This paper was read before the Royal Society in 1813, hence it appears that Dr. Wells anticipated Darwinian theories by a considerable space of time. Wells apologises for discussing a subject that only ad-

jectural reasoning, and fears that his article may be "rather fanciful than just." As happens far too often, this paper was overlooked, and Dr. Wells has not received the credit that was due to him. His medical work is of no small importance, though his name has been often saved by a few, and, as we have before pointed out, his optical writings are of great value, and no serious man can afford to neglect them.

## THE ILLEGAL USE OF NEGATIVES AND PHOTOGRAPHS.

I dealt a few weeks ago with the relations of a photographer to his customers in the matters of the custody and use of negatives made in the usual course of portrait photography. These matters, as we pointed out, are independent of copyright considerations, but are based upon an implied contract between the photographer and his customer, which binds the photographer to act in accordance with the desires of his customer. In now passing to consider the rights of a sitter, it may be stated at once that rights exist by virtue of the clause in the Copyright Act to the effect—we abbreviate the wording of the Act for the sake of clearness—that the copyright in a photograph shall be the photographer's except when "the negative of any photograph shall be made or executed for or on behalf of any other person for a good and valuable consideration, the person so executing the same shall not be deemed to have assigned the copyright thereof, unless it be expressly reserved in writing, signed by the person or on whose behalf the same shall be so made or executed, but the copyright shall belong to the person for whose behalf the same shall have been made or executed."

The precise meaning of this clause were clearly understood on many occasions whereon photographers have behaved in a very foolish manner, and with an arrogance which has had to retract, would not have been so markedly expressed in ordinary language, the clause of the Act amounts to this:—When a photograph is taken for someone, or ought to pay, for it, the copyright in the photograph belongs to that someone; or if the photographer is paid a regular wage for taking the negatives, the copyright in the photographs belongs to his employer. In other cases the customer or the employer is the possessor of the rights which are granted by the Copyright Act. Let us now draw attention to our interpolated phrase immediately above, "or ought to pay." The distinction is not actually made in the Act, but it has been very clearly drawn by cases in the High Courts, and we refer to it because it is very easy for photographers to reason themselves and to arrive at a conclusion quite opposed to that of the law on this point. It seems reasonable, and, to argue in the case of a customer who has not paid for his photographs, and who, in the ordinary course of application by the photographer, cannot be made to pay for them, that, since the photographer has received no good and valuable consideration, the copyright in the photographs is his, and he can do what he likes with the prints regarding their multiplication or reproduction. Yet the law does not uphold this view of the matter, but, with a kind of almost Gilbertian logic, refuses to distinguish between paying for the photographer's work and owing for it, for example, Mr. John Smith commissions a photographer to take a photograph of his (Mr. Smith's) residence, and, if, after the photographs have been delivered, negotiation and persuasion are ineffective in getting the money out of Mr. Smith, the photographer is not at liberty to set upon a policy which he may formulate to himself in these words:—"I see no chance of getting the money from Mr. Smith. I will straightway issue postcards of Mr. John

Smith's house and thereby recover the amount of which I am out of pocket, and perhaps make a bit more as well." Not so; the law says that Mr. John Smith's order is an implied promise on the part of Mr. John Smith to pay for the work, and on that promise he can be sued for the money. Meanwhile the law supports Mr. John Smith's right to do what he likes in the way of having the photographs reproduced, and if he objects to any reproductions of them appearing he can obtain an order to have them withdrawn, or can bring an action for infringement of his copyright.

We say that the above ruling of the Courts is not an ideal one, for obviously it lends itself to the perpetration of fraud by unscrupulous persons; but a mature consideration of the circumstances which attach to copyright will lead to the conviction that it is the most practicable solution of the difficulty. And we would impress it upon many of our readers of whose misunderstanding of it we have frequent instances. It is very common, for example, to hear of a photographer who has taken certain photographic groups of his local football club by whom he has been paid for the work. The club afterwards asks him for a price for a large number of postcards, but because it is not satisfied with his terms, places the order elsewhere with another photographer, who prepares his negative, of course, by copying one of the prints supplied by his rival in the first instance. What does the latter do in many cases such as this? Ignorant of the fact that he has no right to make a single copy from the negatives in his possession, he hastens to issue postcards of the particular subjects, and is highly incensed when his erstwhile customer, the football club, calls his attention to the fact and demands the withdrawal of the cards. Yet the most cursory study of the Copyright Act would save photographers from making a ridiculous display of their ignorance in regard to a document the provisions of which should be at their finger ends.

It not infrequently happens that doubt exists as to whether the photographer did actually receive a good and valuable consideration, or whether he did not actually take the photographs in the first instance without receiving payment. If he did, the copyright attaches to him, and his possession of it is not altered by the fact that he afterwards sold prints from the negatives to the parties in question. Without going further into the intricacies of copyright law, we may cite the imaginary but quite common case of a photographer who, while out executing some commission, meets with an attractive subject—such as a boating or picnic party—negatives of which he takes on the understanding that there is no payment to him, but that any of the parties may purchase copies from him if they choose. In such a case undoubtedly the copyright is the property of the photographer, and the reproduction of a copy by any one of the party who may purchase it will be an illegal act and may be made the subject of action by a photographer.

It will be noticed in the portion of the Copyright Act which we quoted in the first paragraph above, that it is expressly stipulated that the person so executing the photograph—that is, the photographer—shall not retain the photograph unless it be expressly reserved to him by an agreement in writing. This would suggest that in the absence of payment of a good and valuable consideration to the photographer, the copyright becomes his without any written agreement. But it should be remembered that if any action should arise as to the possession of the copyright, it is pretty safe to predict that in the case of sitters who visited the studio of the photographer he will be called upon to prove the fact of his having done the work without receiving a good and valuable consideration. In other words, the safe course to follow in the case of sitters, the copyright in whose photographs it is under-

stood are to be retained by the photographer, is to obtain a written agreement in writing to this effect. A convenient form of such agreement is the following, which is based on that recommended by the executive of the Professional Photographers' Association to its members:—

To Mr. ....

In consideration of your allowing me a reduction from your usual terms for taking photographs of me or on my behalf this day, I hereby agree that the copyright in such photographs shall be reserved to you, and that I will not deal in any way with the photographs to prejudice your interest in the copyright.

Dated the ..... day of ..... 190....

Witness .....

At the same time that we state that any copying of the photographs in regard to which there exists an agreement such as the above, will be an infringement of the photographer's copyright, we would insist with all the emphasis we can command that the photographer has nothing to gain from an obstinate and unreasonable exer-

cise of his rights. We could cite instance after instance in which greater leniency in regard to this matter would have advantaged the photographer. There is no good to be gained from attempts to make something the way of a copyright fee when by so doing one is injuring the amicable relations between oneself and sitters, the copyrights in whose photographs have proved valuable. Leading photographers, a great part of whose business depends upon the establishment of copyrights in this way, know better than kill the goose which lays the golden egg and if, for example, a sitter desires to reproduce a copyright photograph of herself for some private or personal purpose, such as a professional card, or if she wished to give it to some journalist who was preparing a special illustrated interview, they will gladly waive their rights for the sake of showing a courtesy to the sitter, and, indeed, to do anything else would be very bad business.

Exigencies of space prevent us from entering upon other forms of illegal use of negatives, but the one or two cases which we have instanced in the foregoing remarks include the most common of them, and if studied by the reader should prevent him from acting injudiciously.

## A MEASUREMENT OF THE EFFICIENCY OF DARK-ROOM FILTERS.

(A Paper read before the Royal Photographic Society.)

THE following paper is an account of an attempt to compare directly the visual intensity and the safety of differently coloured dark-room filters with a view to being able to use a filter of definite colour, knowing the intensity of light which will be obtained, and at the same time the danger of fogging attending this use.

In the earlier days of photography, when less attention was paid to theoretical requirement, and plates were far less colour-sensitive than they are to-day, the illuminating screens for the dark room were constructed mainly of commercial red glass, and of the cloth impregnated with lead chromate known as canary fabric.

Now, while the older red glass coloured in the mass frequently cut out the whole of the violet and ultra-violet, and was a quite satisfactory illuminant, samples of glass were found which were of a most unsatisfactory nature, and this led to the general impression, which has been voiced by several writers on the question of safelights, that an indefinite degree of safety with great intensity may be obtained by cunningly devised screens, and from this has arisen the issue of numbers of safeguards, liquid, stained film, and glass, designed to give great intensity with great safety, at any rate according to the prospectuses. Such, for instance, are the fluid cells which have been issued at intervals; you are told that with certain solutions you can use great intensity of light in the dark room with perfect safety, and some years ago Mandarin Orange G extra was recommended for this purpose, a dye which has the great advantage for some spectroscopic work of transmitting the whole of the extreme violet and ultra-violet, so that it is a typically unsafe dye to use for dark-room illumination.

Provided that the whole of the blue is cut out in the case of a plate not sensitive to green, and the whole of the blue and green in the case of a plate sensitive to green but not to red, then the safety of the safelight must be a question of intensity, and the decision as to the use of any particular arrangement must be dependent on the relation between the sensitiveness of the plate and the sensitiveness of the eye for any particular colour. Possibly the best example that can be taken to illustrate this point is the discussion of the

spectral absorption of a safelight to be used with a panchromatic plate.

It may be taken that this panchromatic plate is sensitive to the whole of the visible spectrum, and for the purposes of this discussion we will assume that for the light with which it has to be used it is *equally* sensitive to the whole of the visible spectrum; an assumption which may not be true in practice, because the distinctly yellow light sources used in dark-room lamps, oil lamps and so on, will probably produce more effect in the red than in any other portion of the spectrum; but assuming that the plate is evenly sensitive to the spectrum, it is clear that it is only a question of time for a screen of any colour to fog that plate equally, and three screens be made such that their actual absorption measured in the spectral photometer for their transmission regions are equal, these screens being blue, green, and red, then in the same time our plate will be equally fogged by all three of them.

But if they are examined visually, it will be seen that they are by no means equal in visual intensity. The blue is the far the darkest, the red being intermediate between the green and the blue. So here we have one consideration in choosing all safelights, the blue is of but little use for purposes of vision, and even on a panchromatic plate will be very dangerous, equally with all other colours; so that to start with we must abolish the blue.

Subtracting the blue from the light, we are left with yellow light composed of a mixture of red light and green light. If the light be intense, the eye is nearly equally sensitive to the red and green portions of this yellow light, but as the intensity is diminished it follows, from what is known as the Purkin phenomenon, that the maximum of visual intensity shifts towards the bluish green, abandoning the yellow, therefore the visual intensity of a dull red light—that is to say, weak red, not a deep red—is very small indeed.

With a panchromatic plate we cannot use much light of any colour, and if we have very little light, the red light in it is practically useless for the purposes of vision, while it is still actively harmful to the plate, which displays no Purkin

tion; so that clearly we should cut out the red as the blue, leaving us only a green light, and we see the ideal colour for a safelight for panchromatic plates is a pure green, having neither blue nor red in it, and the depth of this must depend on the sensitiveness of the plate and the time for which the plate is to be exposed to it. The same considerations which have been discussed in the case of a panchromatic plate apply equally to all other plates. An additional precaution, that, as far as possible, if a plate has a region of insensitiveness, as all plates other than those that are panchromatic have, then the safelight should transmit light of this region, provided that the transmitting intensity of that light is sufficiently great to make a light of equal intensity of that region as safe as a light which affects the retina more, but is in a region in which the plate is sensitive. For example, pinachrome plates have small sensitiveness in the extreme red above 6,800, and a green screen transmitting light to which the eye is perfectly sensitive can be used of equal visual intensity to the deep red light without any greater lack of

accuracy in our experiments, then, on these general conclusions, we have made a number of observations of the visual intensity of the photographic effect of variously coloured safelights, with a view to designing a series of screens adapted for different purposes to give a known amount of safety, and equally a known amount of visual intensity. One cannot describe the conclusions which we have arrived at particularly satisfactory; we have shown us more forcibly even than we suspected that it is not possible to combine intensity with safety, and we have concluded to which all expert photographers have arrived that it is necessary not to trust the dark-room lamp and to expose plates to it as little as possible, is based on the best practice, and cannot be avoided by any combinations of screens.

It is, in fact, only one screen for a dark-room lamp which is described as indefinitely safe, and that consists of a screen of cardboard, so that one must decide what degree of safety can be permitted, a conclusion which will vary with the carefulness or carelessness of the worker, and with the method with which he can manipulate his plates, fill his slides, his dishes, and so on.

The apparatus used in the measurements of visual intensity is extremely simple, and perhaps not very satisfactory, but it has been unable, at any rate at present, to design a better one. It must be remembered that photometric determinations of visual intensity are of but little use; what is required is a determination of the visible light at the disappearing point, that is to say, a measurement of the amount of cutting out of light which that coloured light will stand before it becomes invisible.

### Lamp, Method of Work.

The method of doing this was to employ a large electric lamp as shown in Fig. 1) to which different bulbs could be fitted. The front of the safelight in this lamp was placed across by sticking lantern-slide binding strips on the lamp. The image of this was then focussed on the ground glass of a camera, and in front of the lens was placed a red iris diaphragm, the aperture of which could be varied from the setting of the handle. Measurements were made by closing this diaphragm until the image of the cross on the ground glass disappeared; the amount of light which was passing then being calculated.

The lamp employed deserves some notice. It was designed by S. H. Wratten for use with electric light for dark room illumination, and has the very great advantage that it gives out perfectly diffused light, no direct light being emitted.

The lamps are comparatively easy to make, requiring only a wood frame and cardboard, and are completed and made light-tight by gluing brown paper over the joints.

It is of importance in dark room illumination, when other things than the actual plate require to be seen, that diffused light should be used; by using diffused light, a great deal more can be seen with the same intensity of light falling on the plate, because the whole of the room is lighted instead of the plates only upon which the direct rays of the lamp fall. Of course, one can imagine cases where it would be convenient to have a restricted cone of light into which all the materials for use could be gathered and from which the plate would be rigorously excluded, but in ordinary dark room work the inverse plan is distinctly the best.

The accuracy of the measurements made with this apparatus, although low, is good enough for practical purposes, though it is quite insufficient to draw any theoretical conclusions as to the physiological value of different light sources, and the results are not in any way put forward as scientific measurements, but as rough approximations suitable for consideration when deciding on the use of particular safelights. The eyes of both observers appear to be quite normal with regard to colour distribution, a point of some importance in work of this kind.

The photographic intensity was easier to measure with accuracy, because it is part of the routine work of the laboratory.

### Method of Work.

A large water-cooled acetylene burner was used in front of the exposure machine, its intensity at the sector wheel being 190 candle metres; the safelights were put between this burner and the exposure machine, and the plates inserted in dark slides behind the sector wheel and exposed for a definite time. The exposures ranged up to forty minutes. After development, the densities were measured and the inertia curves plotted, the effect being reduced from the relative inertias.

### Colour of Screens Employed.

All screens used in this work had, in addition to any other material mentioned, one sheet of glass coated with a film of gelatine strongly dyed with tartrazine, which cut out all wave-lengths below 4,900 A.U. This alone was used for the yellow safelights, the additions being as follows:—For the orange safelights a screen of eosine, cutting out all wave-lengths below 5,500; for the red safelight, a screen of pinatype red was used, cutting out all wave-lengths below 5,900; for the

deep red safelights, a screen of methyl violet was used, cutting at 6,200; the blue-green safelight passed light between 4,900 and 5,600; the naphthol green safelight between 4,900 and 5,750, though all these were modified by the papers which were also added. The spectrum absorptions are shown in the photographs (Fig. 2).

#### Plates for which Screens are Designed.

The screens mentioned above were employed for the following plates:—Yellow and orange for an ordinary extra rapid plate, the one used being the one called by Wratten and Wainwright the "Improved Drop-shutter"; the red was used for the "Speed" plate, an ultra-rapid plate; the methyl violet for an erythrosin plate, the "Allochrome," for which also the blue-green safelight was designed for the benefit of red-blind users, having had several requests for a special safelight from friends of ours who can either scarcely see red at all, or to whom the red light is extremely irritating. The naphthol green safelight was for use with a panchromatic plate.

These different glasses were cut down in intensity by the insertion of blotting paper, tissue paper, paper soaked in aurine and methyl violet, and paper soaked in acid green; the absorption of these papers were separately measured.

With regard, firstly, to visual intensities, it was found that the visual brightness of the various safelights was as follows:—

#### Visual Intensity Table.

1. Ground glass alone .....	200
2. Tartrazine and ground glass .....	133
3. Tartrazine and ground glass and eosine .....	80
4. Tartrazine and ground glass and red .....	28
5. Tartrazine and ground glass and methyl violet..	7
6. Tartrazine and ground glass and blue-green .....	7
7. Tartrazine and ground glass and naphthol green	1.60

Absorptions of two sheets of thin white tissue paper measured on the same scale, 1.72; that is, the tartrazine and methyl violet screen has an intensity of 7; if we insert two sheets of tissue paper, this must be divided by 1.72, reducing it to 4.1.

One sheet of blotting paper divides the intensity by 3, so that if one sheet of blotting paper be inserted in the methyl violet safelight the intensity will be 2.34. One sheet of aurine paper in the red safelights divides the intensity by 4.1, so that the methyl violet safelight with aurine in it will have an intensity of 1.7.

The addition of one sheet of green paper to the green safelights has the effect of reducing the blue-green nine times,

and the naphthol green twelve times; so that the intensity of the standard green safelight, which contains naphthol and tartrazine glasses and one sheet of green paper, is 1.72.

The safety of these safelights is shown by the next table, which gives the amount of exposure necessary to produce the same effect in all cases upon the plate for which the safelight is stated to be designed:—

RELATIVE SAFETY TABLE.

	Safelight.	Exposure to give result.
1 {	a. Tartrazine on I.D.S. ....	1
	b. " with tissue paper .....	2
	c. " with blotting paper .....	3
2 {	a. Eosine on I.D.S. ....	1
	b. " with blotting paper .....	2
	c. " with aurine paper .....	5
	d. " Naphthol green on I.D.S. ....	2
3 {	a. Red on Speed .....	1
	b. " with aurine .....	2
	c. " with aurine and methyl violet paper .....	10
	d. Methyl violet on Speed .....	10
4 {	a. Methyl violet on Allochrome .....	5
	b. " with aurine .....	15
5 {	a. Blue green on Allochrome .....	1
	b. " with green paper .....	1
6 {	a. Naphthol green on Panchromatic .....	1
	b. " with green paper .....	6

Combining these two tables we get the efficiency:—

	Safelight.	Intensity.	Safety.	Efficiency = Int. x Safety.
1 {	a	133.0	1.0	133.0
	b	77.0	1.7	131.0
	c	44.0	3.0	132.0
2 {	a	80.0	14.0	1120.0
	b	27.0	25.0	675.0
	c	20.0	50.0	1000.0
	d	1.60	22.0	35.2
3 {	a	28.0	6.3	176.4
	b	7.0	25.0	175.0
	c	3.5	100.0	350.0
	d	7.0	100.0	700.0
4 {	a	7.0	55.0	385.0
	b	1.75	150.0	262.5
5 {	a	7.0	1.0	7.0
	b	.78	9.0	7.0
6 {	a	1.60	2.0	3.2
	b	.135	64.0	8.7

It will be observed from this table that the naphthol green screen used with the I.D.S., although reasonably satisfactory, is extremely inefficient, but that, on the other hand, the methyl violet for the Speed plate is desirable, as the efficiency is greatly increased by it.

The Allochrome safelights are clearly satisfactory, having high efficiency, but the blue-green are very unsatisfactory, in order to get reasonable safety can scarcely be brighter than the panchromatic safelight. The low efficiency of the green safelights is, of course, due to the fact that they are used with plates which are highly sensitive to green light.

In order to make practical use of these results, it was necessary to know the standard of safety required for practical work in the dark room, and it was found that with an electric candle power lamp, and the plate at a distance of one meter, taking as the standard of safety that a visible fog should not be produced in half a minute, though it might be in a minute—if the dish is covered this should be quite satisfactory—it was found that for this safety a number about 100 on our scale was necessary; so that reading off from the table we see that we can get an intensity with the I.D.S. of 1.72. With the Speed, by using methyl violet and a strong lens of 14, with the Allochrome of 7, and with the panchromatic of about .15; and having attained these intensities, any exposure intensity is obtained with the knowledge that the addition

means additional unsafety in direct proportion to that must be pointed out that the favourite method of sing the size of the dark-room lamps to give more light ed in nothing; that method is based on the assumption he fog is caused by small amounts of blue light passing lters; but the results given above make it abundantly that the fog with these filters is not owing to this, but

simply to excess of light of the colour which it is intended to transmit.

Our best thanks are due to Messrs. Wratten and Wainwright, Ltd., for permission to publish these results, which were obtained in their Research Laboratory, and especially to Mr. S. H. Wratten, who has made the experimental safelights required in the work.

## THE COLLODION PROCESS.

In the following article, which is the first of a series, is commenced a synopsis of the working of the wet collodion process one of the oldest experts in the handling of the wet collodion plate. Mr. Foxlee's experience of wet collodion commenced after the introduction of the process in the fifties of the last century, and his notes therefore embody the experience ed in fifty years' practical working and intercourse with the past generation of photographers. The articles, we believe, be of service to the numbers who, for technical purposes, still make use of the collodion process.—Eds., "B.J."]

### The Wet Collodion Process in Practice.

Collodion is not yet an obsolete process, for it is still largely for purposes such as process blocks, photo-engraving, photography, photo-zincography, and also for the making of aged negatives for carbon enlargements, and other work. a notable fact that where bichromated-gelatine processes concerned, better results are obtained from collodion nega- than from gelatine ones. It is for this reason that they so generally employed for the processes just mentioned. it is practically an unknown process to the majority of who have only entered the ranks of photography within last twenty years or so. Up to the general adoption of ine plates in the early eighties, it had been, for thirty s, the only one that was employed for general purposes. wet collodion process is looked upon by many as being exceedingly difficult one to work, however, it is not so in ity, but there is no gainsaying the fact that it is one that ires to be learnt, as it is very different from present-day ography, when the plates are purchased ready for exposure ie camera. It is true that the silver bath is at times liable play tricks," but it is easily set right when its little vagaries understood.

ter working the collodion process exclusively for over a ter of a century, I can say of it, "With all its faults I love ill"—for some purposes. Compared with gelatine, collodion undoubtedly a slow process, yet with it, instantaneous pictures e successfully taken, as witness the street scenes of Paris, n by the late Mr. Wm. England, those of the streets of don, by the late Mr. Valentine Blanchard, and others, to nothing of the animals in the "Zoo," by Mr. Frank Haes, the late Mr. Fredk. York. All these pictures will hold r own against those more recently taken on gelatine plates. has just been said that the collodion process is one that ires learning, and I might add that the knowledge gained he practice of the gelatine process will not aid much in the ming of it. Indeed, if I had to teach the collodion process a youth of ordinary intelligence, I would prefer that he old know nothing at all of gelatine. The two processes, so as the manipulations are concerned, are so widely different, a certain degree of, may I say "slovenliness," in working, ch is quite permissible in the one would be fatal in the er.

In this and subsequent chapters I shall endeavour to give a practical instructions as will enable anyone to work the odion process successfully after a very little practice. In ug so, it may possibly seem to some that I shall be dealing necessarily with trivial matters, but it should be borne in d that the success or failure in working the process depends n, apparently, trivial points.

### Chemically Clean Glass.

The first operation in the collodion process is the cleaning of the glass upon which the negatives are taken. To some, it may appear superfluous to take up space to describe how to clean a piece of glass, but it is not so, for there is a wide difference between what is, in appearance, a clean glass, and one being in a state of chemical cleanliness which is so imperative for successfully working the process now under consideration— plates that may to all appearances be perfectly clean, yet when the negatives are developed upon them will show streaks and markings, the cause of which may possibly puzzle a beginner. Moreover, unclean plates tend to injure the sensitising baths in which they are put.

### Cleaning Glass.

The methods of cleaning the plates are numerous, but they need not all be described. The following is one that may be relied upon:—In the first place the edges of the plates should be roughened. The object of this is twofold, it gives a better hold to the collodion, and prevents the leathers being cut in the polishing. If the plates are large the roughening is best done with a piece of ragstone. If small—say up to 12 by 10—it may be more quickly done by scraping the edges of two together. The plates as received from the glass warehouse are put into a rather strong solution of carbonate of potash—common pearl ashes—and allowed to soak for a time. They are then rubbed over with a piece of coarse flannel to remove all dirt, and then well rinsed back and front under the tap, and stood up in a rack to drain and dry. If the plates are of small size, say up to the above-mentioned size, the potash may be rubbed over with a piece of rag fastened on a stick, allowed to rest for a few minutes, and then rinsed under the tap. When dry, the plates are ready for polishing.

### Polishing the Glass.

As in the preliminary cleaning, there are as many ways of the final polishing of the glass. My favourite method is as follows:—In a bottle put some methylated spirit, free from the mineral spirit, and add a few crystals of iodine, sufficient to give it a dark sherry colour. Then fit a cork with a notch in it, so that the spirit can be jerked through it. Into a wide-mouth bottle put some good Tripoli, and tie over the mouth a piece of rather coarse muslin. Lay the plate on some quite flat surface, and jerk some of the spirit on it, and then dredge on some of the Tripoli. Now take a piece of coarse flannel and rub well over the surface, using some little pressure, and allow to dry. The same flannel will last a long time. When dry, the Tripoli is wiped off with a perfectly clean glass cloth—care being taken to clean it off the back and edges of the plates, which

are then ready for the final polishing. That is best done with a chamois leather.

#### How to Prepare the Polishing Leather.

To cleanse the leather when new it should be well beaten and shaken to get out the dust that all new wash-leathers contain; it should then be washed in cold water containing a little soda, and afterwards well rinsed in several changes of water and dried. As the leather dries, it should be stretched now and then to prevent it becoming hard when dry. In use the leather should be doubled up to form a rather tight pad, and the glass polished with a circular motion. As a test as to when the plate is clean, it should be gently breathed upon at different parts, and if the moisture flies off quickly and shows no signs of marks or streaks it is satisfactory. If it does not, the polishing must be repeated until it does. Here is a "wrinkle." The polishing leather should not be too dry, by that is not meant that it should be really damp. If it is "bone dry," it passes over the plate without polishing it, and at the same time excites electricity, causing the glass to attract dust. Whereas, if it contains a slight amount of moisture, the leather clings to the glass and effectually polishes it. Should, by chance it become abnormally dry, it should be hung in a damp place for an hour or so, or it may be rolled up and wound round and round with a slightly damp cloth and allowed to rest for a time.

#### Instead of Polishing—A Substratum.

Instead of cleaning and polishing the plates, as just described, some prefer to coat them with a substratum of albumen. This saves the time and trouble of polishing, and, to an extent, prevents the collodion leaving the glass during the manipulation. It has the disadvantage of, after a time, disordering the sensitive

bath. The albumen subtratum is prepared as follows:—Winchester quart bottle, put some fragments of broken the white of one egg freed from germ, a quart of water, few drops of liquor ammonia, and shake vigorously for minutes. Then filter through a plug of cotton wool placed in the neck of a funnel. It is applied thus:—After the have been cleansed in the way described, and after rinsing, they are flowed over two or three times, carrying water before it, with the albumen, then placed in a dry, when they are ready for use.

#### To Clear the Films from Old Negatives.

Hitherto we have been dealing with new glass, but in the collodion process the glass is often used over and over again and in many cases the negatives have been varnished in the simplest way of dealing with varnished negatives is to immerse them in a tolerably strong solution of American Pearlash and allow them to soak for a day or two. Pearlash is used in place of American potash. This will dissolve the varnish and leave the glass practically clean. After removal of the potash, it is advisable that the plates should be polished or flowed over with very dilute sulphuric acid, then again rinsed with water and allowed to dry. This ensures the removal of the alkali, which would otherwise have a tendency to injure the silver bath. An excellent detergent for use is a saturated solution of bichromate of potash, to which is added eight per cent. of sulphuric acid has been added, but should be taken with it, as it has a very pernicious action on the skin.

E. W. Fox

\* American potash is sold by the druggists, and is, I believe, largely dyed. It is purchased in large lumps or small boulders, and of a brownish colour. It is, I think, a crude kind of hydrate of potash.

## A "SNAP-SHOT" CAMERA FOR THE USE OF ARTISTS.

THE object of this invention is to provide a camera which will enable "snap-shots" to be taken with a minimum chance that the persons included in the field of view should be aware that they are being photographed. To obtain this result the lens is placed as nearly as may be at the back of the camera, instead of at the front, and in consequence of this arrangement the photographer has the object he is taking, so far behind him, as to be quite out of the range of natural vision. Hence no suspicion would be created in the mind of the

Fig. 1.

person actually being taken of the probable subject included in the picture.

In addition to the high degree of secrecy given to the operator by this camera, the instrument will be found to possess many incidental advantages over hand cameras of the ordinary construction, as for example:—

1. The image being formed by reflection, the camera is much shorter

than in the ordinary construction, hence it is much more easily held steady enough to secure sharpness.

2. The instrument is exceedingly simple in its construction, light and portable, and it is ready for use on the instant.

3. Being specially adapted for use with high-power lenses (f/16), it easily lends itself to securing snap-shots in dull light.

4. The image is seen practically on the plate itself up to the moment of exposure. There is thus every opportunity of securing the best effect, and there is no trouble with eye shades, etc., as is the case with the reflecting cameras at present in the market.

#### A General Description of the Camera.

The camera is made on the reflecting principle, and is almost the reverse of the usual arrangement, the lens being at the back looking out over the operator's shoulder. The system will be understood by reference to Fig. 1.

O is the objective, the image from which is received upon a plain mirror M, whence it is reflected to the plate P. In front of the plate is stretched a focussing screen S which acts both as a focus screen and shutter. S is, in fact, purely and simply a "focal-plane shutter" so made as to pass as near as possible to the sensitive face. This focal-plane shutter is naturally of black material, when it is "set" a white patch, the exact size of the plate, is seen in position opposite the mirror, and on this white patch the image is focussing. This image is seen—and magnified—by the eye lens.

A small shutter should be provided which would automatically open the eye lens at the moment of exposure, and re-open it when the focal-plane shutter is set.

Fig. 1 is a sectional view of a camera for plates cut films  $2\frac{1}{2}$  inches square. The lens intended to be used with this camera is  $4\frac{1}{2}$  in. focus. The image from the lens would fall on a plane mirror of about  $2\frac{1}{2}$  inches square. The side of the camera, i.e., the part carrying the mirror, is hinged to the focal-plane shutter frame at one end, and to the back, i.e., the part carrying the

at its other end; the back is, in its turn, also hinged to the front carrying the lens, which is again also hinged to the frame of the shutter. By these dispositions of hinges (the hinges may be of other), the front board, back and side will fold down quite flat, as indicated in Fig. 2. When closed, the lens turns up

Fig. 2.—Camera closed.

the thickness of the shutter frame, a thin flat metal cap serving cover to it when in the closed position. A simple clip or fasten- will serve to keep the camera closed. When this is released the era would open of its own accord by virtue of a spring inserted between the shutter frame and the side-piece, as shown in the draw-

The extent to which the camera would open would be regulated by an inelastic tape or ribbon. The opening of the camera for use would thus be effected in a moment, a matter of great importance for

shot work. Below are two sketches, one showing the camera open, the other showing the manner of holding it when in use. The young lady is here represented as taking a photo. over her left shoulder. It will be seen the nose passes to the right of the sloping side of the camera, thereby enabling a very short eye tube to be used—it may be, in

Camera Open.

Camera in Use.

vice, one could dispense altogether with the eye tube or shade figured in Fig. 2. In the case shown in the sketch, the second eye is pressing the detent to make the exposure. In case the subject to be photographed lies more conveniently over the right shoulder, it is only necessary to reverse the position of the camera,

seeing then the image with the right eye, and actuating the detent or press button with the thumb, of course, then of the right hand. In either case, the thumb being opposite to the fingers, a very steady pressure can be given, and one not at all likely to shake the instrument.

In Fig. 3 a camera on the same principle is shown, but adapted for work on a roll film. In this instrument a lens of about 8 in. focal length is shown, and the picture would be about  $3\frac{1}{2}$  in. square. In a design such as is shown in this figure, it is evident that there would be no difficulty in bringing the roll film into the closest approximation to the shutter screen. In fact, the two might be advantageously in actual contact. Such a camera would be smaller, of less weight, and more quickly set up for action than an ordinary "Kodak." Having a longer focus than is ordinarily given to instruments of this kind, it would have a corresponding advantage to the artist; who needs, not a general view, but a detailed "bit" of a subject.

Fig. 3.

### Some General Remarks.

#### REVERSAL.

Of course, in a reflecting camera such as is described above, the image would be reversed, but it is not considered that this would be any serious drawback, for the following reasons:—

1. The most convenient way in which to print from very small negatives is to print them in the lantern by bromide papers, etc. In this way they can be conveniently enlarged to a certain degree, and, of course, when this plan is adopted, the reversal of the plate is of no consequence whatever.

2. With many subjects such as groups of people, etc., reversal is, in itself, of no consequence. But if the operator has a rooted objection to it, and desires to print direct in ordinary printing frames by contact, he has—

3. The choice of taking the picture through the film, or of printing through the back, or of using single transfer carbon. In the opinion of the writer it would be, in all cases, preferable to work through the film, as with the exceedingly thin dark slides necessary it would greatly tend to the safety of the films if the sensitive surface were placed inwards; the shutter might then actually touch the back of the film without any fear of injury, and the same may be said of the roller film shown in Fig. 3. If this were placed so as to present the back of the film to the shutter screen, the latter could inflict no damage upon it, even if in quite firm scraping contact during the exposure.

No doubt this form of camera could be adapted to work with a "film pack."

It is evident that with cameras made as described, the image exactly focussed on the screen would fall slightly out of focus on the sensitive surface.

In the form shown in Fig. 3 with the roll film, it is thought that this error would be too small to be noticed, as it need not exceed the  $1\text{--}1,000\text{th}$  part of the focal distance. But with the smaller camera, or with one to use with dark slides and cut films, the error may be of more importance. It seems to the writer that about  $3/32$  in. would be practically the distance between the focussing screen and the sensitive surface; but even putting it at  $\frac{1}{4}$  in., a correction is very easily made.

The image being reflected it would be only necessary to move the lens half the distance required for the correction, and it would be a very simple thing to make a little lever or wedge which should draw the lens in 3-64ths or 1-16th in. at the moment of making the exposure. There is another manner, however, in which correction could be made in a very neat and scientific fashion; that is, if the form of camera should take any large degree of commercial success, it might be worth while to construct a lens specially for use with it, in which case it would be easy to make one in which the chemical or working focus was thrown back from the visual focus by just the amount needed for use with roll films as in Fig. 3.

#### The Eye Lens.

The eye lens is shown inserted at an angle with the back of the camera. In Fig. 1 the lens is at too great an angle; it should evidently be directed to the centre of the field of view. The writer has found by experiment that a watchmaker's lens of suitable focus gives a very good definition all over the plate, about 2 in. square, with, of course, the best focus in the middle. It is thought that if the eye

lens were specially made, a good general definition might be obtained. The angle at which the picture is seen is not much more than that which a stereoscopic picture is often viewed.

#### Demand for Such an Instrument.

It is felt by many who practice art for art's sake, that an absolutely secure snap-shot in which the object of the worker would not be detected, would in a great many instances yield results far anything obtainable by the camera in its ordinary application. It has only to present a camera towards any group of people, young or old, to see the instant feeling of stiffness and constraint that pervades the scene in a moment. No skill or persuasion on the part of the operator can overcome this trouble. By untiring patience or perhaps by good luck one can sometimes get a passable result, but the veridical and pluck of unconscious realism can only be obtained by the means of being unconscious of what is being done.

Hence it is felt that combined with the other advantages of novelty, etc., etc., this camera should have a considerable commercial value.

NELSON K. CHERILL

## THE ART OF PHOTOGRAPHY.

["Truth" of last week presents its readers with a photographic supplement. The following extract may be interesting and instructive reading on the ever-burning topic, Is Photography Art?]

"PHOTOGRAPHIC," when referring to a work of art, has by now become as much a term of opprobrium as has "a really nice girl," applied to the premier work of Nature. Pianists have been known to praise the pianola—some of the more famous of them, at any rate—perhaps because they have suffered from the originality which minor musicians seek vainly to inveigle into their performances; and Melba is said to have a predilection for the gramophone, which shows her a woman of wide sympathies; but to hear a painter or a writer on art praise a photograph, except with infinite condescension, is as rare as it is to hear a farmer praise the weather.

Even did the painter owe nothing else to the photograph, he should yet be grateful for the moral exaltation it provides for him in his own estimation. By standing, to his mind, upon the lower step, it converts his own into the higher one. By being "photographic," it makes him "artistic." "I may be at the very bottom of my brotherhood," he reflects, "and the bottom is neither very light nor very airy; at all events, I am above the photograph, which only copies and does not create." It is largely due to the invention of photography that the painter has come to spell his Art with such an extremely large A, and that without shame. In the old pre-photographic days the painter considered himself a workman; it is true that the excellence of his work gave him some claim to be so considered. In our own time—and that largely owing to the invention of the camera—the painter has ascended to a higher, super-human sphere; he is a creator, and it follows that mere humanity has no right to judge of the excellence of his workmanship. What is more, he indirectly owes it to the photograph that "art" tends more and more to drive photography itself out of suburbia. It is not many years since the suburban drawing-room depended for the decoration of its mantelpiece and its piano upon a phalanx of "photos" in plush or oxidised silver frames. But now that the fame of large-A'd Art has penetrated from Poplar even to Putney Vale, the painted drain-pipe and the hand-made bronze fender, direct from the Arts and Crafts, serve to set off the embroidered jumpers of their fortunate possessors, the photograph must give place to the coloured reproduction of the Velasquez "Venus" or Mr. Goetze's latest great religious allegory.

Photography has one fault, which is also a misfortune. It tells—it is, at least, capable of telling—the unvarnished truth without any extenuating circumstances. Who would not prefer to have his portrait painted by the very wildest of New English artists rather than submit himself to the tender mercies of his younger sister's new camera? Photography is the painfully veracious witness in a court where art is too often the corrupt judge. The gods have, at last, given us the gift, but the camera too often shows us as being even worse than others—and they our most candid friends—care to admit that they see us. Naturally, therefore, we say that photography is inartistic, and if we can afford it we go to the painter, who is ready to take us at our own value, and whose work, if unflattering, we can

always denounce as a bad likeness, with the notorious fallibility of the human hand and eye to bear us out.

A good deal of the pother which chronically arises around artistic or non-artistic claims of photography is due to our misusage of the word "Art." Accepted in the confused, almost technical, sense to which we are now grown accustomed, photography is not "Art"—which is by no means to say that it is not an art—the term "artistic photography," used as we commonly use it, is misleading and inappropriate as were "artistic tailoring" or "artistic plumbing." In the truer sense, a photograph may be, and generally is, at least as artistic as a painting—or a chest of drawers. Of course, we all know the artistic-commercial photographer who drapes our shoulders diaphanously, or accentuates our George-Albion-iron-grey hair with high light from above, and makes us worthy of the "Crown" or "Country Life." His are tricks of the trade, worked out by rule of thumb—and verging on the obvious. We have also the more earnest "art" photographer, whose highest ambition is to produce photographs which shall look like etchings or copperplate engravings, or Whistler nocturnes, who, if a man, wears a flannel tie, and if a woman, an expression of other-worldliness and stays, these being the outstanding qualities which attend the true artistic of our own time.

But these latter, though essentially well-meaning—and though, it said, they frequently turn out very beautiful work—are none the less traitors to photography, in that they accept for it a subordinate imitative rôle among the arts. It is an insult to a fine photograph to compare it, to its disadvantage, with an etching or a monochrome drawing—just, as it were, to trick out a first-class county cricket team in the gaiters and apron of a Colonial bishop, and then blame him because he cannot preach in the language of the Otaheitan. Painting and its allied "arts" may be excellent in this way; so may photography. But their ways are not the same, nor their objects. It is true that the invention of the camera has vastly widened the possibilities of the painter—though few painters realise it—in that it has supplied him with a practically perfect eye, which tells him the truth, the whole truth, and nothing but the truth, as an adjunct to his too fallible human eyes, which frequently show him what is not there, and which pander to his mental prejudices like the poorest of poor relations. Every artist ought to be a photographer, and it is because so few of them realise it that we are occasionally treated to exquisitely ludicrous descriptions of the lengths to which they are driven to escape from the fallibility of their own eyes. Thus we read only a very little time back, that a well-known French painter had hypnotised a ballet-dancer, that she might remain in a certain flying pose long enough for him to paint her. Could there be a more pathetic confession of weakness? And all the time the cinematograph is there ready and willing to assist him. Think, again, how totally the whole artistic conception of the action shown by a running horse has changed since snap-shot photography has taught us how a horse

ally runs. The more materials for forming a judgment that are provided for us, so much the less faith are we able to place in our eyes. The Greeks, it is said, could not always distinguish between green and blue; most of us, to this day, are more or less colour-blind. Only needs the perfecting of colour-photography to tell us that preconceived ideas of colour—based on the evidence of our eyes—as faulty as our notion of form has been proved to be.

If every artist should be a photographer, equally true is it that every photographer should be an artist. But he is not likely to be until he realises that the mere pressing of a button will not make a picture. The young photographer, no doubt, honestly believes that when he finds a recognisable reproduction of a near relation upon one of his dozen films he has scaled the heights of Olympus. On the other hand, the true artist-photographer may wander for a week and never touch his camera—yet have none the less high artistic achievement to the credit of that week's work. Just as your painter may or may not be an artist, so may your photographer. In either case the odds are heavily against it.

Great as may be and have been the services which the camera has rendered to art, there is one point in which, it must be admitted, its influence has been altogether harmful. Since its invention the ideal of draughtsmanship has perceptibly fallen. It is as though the artist, realising that it were hopeless for him to compete directly with such a rival, had decided to renounce any idea of drawing and contented himself at all—to make a virtue of necessity and proclaim his own deficiencies of hand and eye as the one infallible sign by which he may know the Real Thing. Is there any other possible explanation of the depth of bad draughtsmanship to which many of our leading painters have descended, without perceptible shame? This more especially in portraiture. "Let the camera attend to such worthless details as the sitters' features," they seem to say. "We will concentrate on what we think their complexions ought to be. And if any object, we will maintain that we paint the soul and leave the body to the care of a soulless machine." Meanwhile the camera continues to extend its sway, swallowing everything in Nature, from the butt of a garden seat to an eclipse of the moon. And unless the painter bestir himself he will one day find himself reduced to producing, *urbis et orbi*, that he scorns the mere external appearances of men and eclipses, and that he only paints their spiritual effluence. About which time the last art-critic who takes himself seriously will retire to Bedlam.

It is a curious—and unfortunate—thing that many of those who are most fervently for the recognition of photography as a branch of High Art, choose its lowest and most humiliating aspect as most worthy of the honour—I mean "fake" photography. It is that it is in their common appreciation of the "fake" that Art and photography come most closely into line. The painter is bound to understand the art of "faking" in its broader sense. He must, if he is to live, impress something upon the observer's eye which is not there. He is perfectly justified—it is the object, and a worthy one, which is his effort. What, for instance, is perspective, but a noble art of "faking"? Your would-be "artistic" photographer, seeing and realising the lengths to which it is possible to carry the deception of a poor, well-meaning camera, sets to work to produce "artistic" photographs which shall seem anything in the world but what they really are. He forgets that while the great object of a photograph is to produce illusion, either mental, moral, or physical, the aim of photography should be to serve truth. Do away with its fulness, and where is the art of photography? It falls to such a degree as that by which, on the day following the birth of the French Heir-Apparent, a photograph of the King and Queen appeared in the shop windows, the latter nursing the Royal Baby. This may be called an intelligent anticipation of events, but not art, and it is scarcely a feather in the cap of photography. The photographer and the painter recognise each other as competitors, setting out by different roads to accomplish different ends, each pushing the other a hearty godspeed at their parting; not as noble seigneur and his twenty-second cousin poor Mr. Camera, with cap in hand at the heels of My Lord Mahlistick in the hope of one day when his Lordship feels peculiarly good-tempered he will offer him his hand to kiss and acknowledge him as the least of his relations.

UDDINGSTON AMATEUR CAMERA CLUB has just been formed, with ready numbers more than forty members. The hon. secretary is A. P. Robertson, 8, Clydeford Drive, Uddingston, N.B.

# A WELL-KNOWN PHOTOGRAPHIC EDITOR QUILTS.

MR. F. DUNDAS TODD, who is well known to many on this side of the water, not only through his visit to the Photographic Convention a few years back, but also from his residence in Scotland, whence it seems but a few years back he migrated, is now giving up active photographic editing. At least this we gather from the following amusing note in "The Photographer":—

"The blow has at last fallen: What was will no longer be. The glory of Chicago has departed, or, to be more chronologically correct, will shortly depart. The 'Suburban Photographers' no longer will, at stated intervals, give heed to the words of wisdom, the pedagogic rulings, the all-too-long Scotch jokes of their late mentor, leader, and chief scrapper, F. Dundas Todd. No longer will photographers in convention assembled be told that they are a bunch of ignoramuses; that a man cannot possibly, at least by all the laws of mathematics, make cabinets at \$3.00 a dozen and not go bankrupt because he forgot to figure his overhead and running expenses.

"F. Dundas Todd has at last found the true answer to his own query, 'What Are We Here For?' (Price \$1.00, red cloth binding.) Back to Nature for his; back to the woods and streams and open prairies, where the elements are the masters and every man is a Trust and a law unto himself. Apples and bees his future field of endeavour. No more for him the photographic Trust; the monotonous gazing, month after month, at the work of would-be pictorialists striving for their '\$5.00 worth of books or materials'; the rendering apart of the foreign journals for copy wherewith to 'fill'; the wearisome editorial on 'Lord knows what'; the waiting for subscription checks which will not come; lucky Todd! Only twice seven years in this country of his adoption, and yet to achieve his most ardent desire! Twice lucky Todd!

"Thrice lucky Todd has disposed of his journal to an incipient magazine Trust, and the 'American Amateur Photographer,' that but recently swallowed the 'Camera and Dark Room' without apparent ill effects on its system, will now absorb the 'Photo-Beacon,' and from the three will arise a new, resplendent publication—and we do hear it whispered that a new name, 'The American Photographer,' is to cover the new combination.

"Well, we shall miss you, Todd—you and your magazine. We could not always comprehend you, nor yet back you in all your statements.

"Like Judge Alton Parker, Todd believed in changing opinions when the old ones were worn out. At one time a most fervent advocate of the realistic picture, a scoffer of brilliant hue at the work of men like Steichen and Colburn, *et al*, he latterly became just as strenuous an admirer of the advanced school—even going to the length of offering a prize in his journal for a picture made sharp—as a novelty. Yes, Todd helped both to the gaiety of the photographic world and to its instruction, and for this last, he will long be remembered. Lucky Todd!"

MR. HENRY O'SHEA, one of the oldest photographers in the south of Ireland, died on June 11, at the age of 78.

THE FOURTH AMERICAN SALON.—The success of this international travelling exhibition has been such that the number of new and important photographic societies in America have asked that it shall visit them during the next season. Therefore the closing date for exhibits is much earlier than it has been hitherto, and all pictures that are to be sent in bulk from British exhibitors, should be in the hands of the collector (H. Snowden Ward, 6, Farringdon Avenue, London, E.C.) on Friday, August 23. As in previous cases, the work which is sent in bulk from England must be unframed, and the authorities of the exhibition pay the customs dues, carriage, and all expenses, including framing of the pictures. Prices of pictures which are for sale are advertised in the catalogue. The selection is made first by a large selecting committee of pictorial photographers, who reduce the number of prints to about a thousand, and then by a committee of painters and illustrators, who make the final selection for exhibition. The whole collection is shown (for about a fortnight in each place) in a large number of different cities through the United States and Canada. In most cases the exhibition room is the Municipal Hall, or some other important art gallery. A few of the pictures are bought (at double their catalogue prices) for the permanent collection of the American Federation of Photographic Societies, and the exhibits are returned about midsummer.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been made between June 10 and June 15:—

**CINEMATOGRAPHS.**—No. 13,407. Cinematograph apparatus and picture sheet in connection therewith. Hans Voss and Hermann Simon, 21, Glockengiesserwall, Hamburg, Germany.

**CAMERAS.**—No. 13,601. Improvements in photographic cameras. Archibald James Erskine, 24, Southampton Buildings, London.

**DEVELOPING APPARATUS.**—No. 13,650. New or improved apparatus for use in the time or stand development of photographic plates or flat films. Frederick Woodward Branson, 30, Park Row, Leeds.

**PERMANENT PHOTOGRAPHS.**—No. 13,736. Process for producing new preparations sensitive to light and suitable for photographic purposes, and for producing permanent photographs by means of such preparations. Johan De Ruiter, 321, High Holborn, London.

**SENSITIVE SURFACES.**—No. 13,835. Improvements in or relating to photographic sensitive surfaces. William Fraser Claughton Kelly, 7, Southampton Buildings, London.

**COLOUR PHOTOGRAPHY.**—No. 13,874. Improvements in colour photography and photographic printing. Frank Wordsworth Donisthorpe, Hohenfels, Combe Down, Bath.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**THREE-COLOUR CAMERA.**—No. 25,399. 1906. This patent describes the camera given in the Ger. Patent on p. 31 of the "Colour Photography Supplement," April 5, 1907.

## New Trade Name.

**WAUKOSCOPE.**—No. 292,403. Microscopes, telescopes, and photographic apparatus, included in Class 8. W. Watson and Sons, 313, High Holborn, London, W.C., opticians. April 23, 1907.

MR. LOUIS E. LEVY has been awarded the Elliott Cresson medal of the Franklin Institute for his etch-powdering machine.

MR. HECTOR MACLEAN, writing in the "Morning Post," says: "While fully recognising the commanding merits of a reflex camera for the photography of many subjects, more especially those taken at short range, there is, I think, an undue disposition to lose sight of the fact that this type of camera is not indisputably the best possible for general use. The BRITISH JOURNAL OF PHOTOGRAPHY, for instance, in referring to its admirable exhibition now open at 24, Wellington Street, Strand, speaks of the high percentage of success achieved by a reflex as compared with other types of hand camera, and considers that those who use the latter are handicapped. Is this, however, the fact? Might one not almost consider that the man whose want of skill makes him use a reflex camera is worse off than one who can obtain his results with a non-reflex one? The reflex camera is bulky, heavy, conspicuous, and slow to sight with. Moreover, it has to be held too low down to allow of the most effective points of view for many subjects. It has, however, many sterling advantages, which are fully set out by special articles in this and last week's BRITISH JOURNAL OF PHOTOGRAPHY." It is, we think, quite a new idea that "want of skill makes" anyone use a reflex camera. Mr. Maclean must be very ignorant of the usual positions in which the non-reflex cameras are held, such as at the waist or under the arm. We should say he had never used a reflex, or he would know that in most cases this type of camera is really held higher than all others, and in some types, particularly those with double mirrors, they have to be held almost eye-high, which is surely not the usual position of the ordinary type, and one which gives a closer rendering from the view point of the eye. The exhibition being still open Mr. Maclean can easily satisfy himself as to how high the reflex cameras must be held.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Reflex Cameras.

Perhaps the best type of camera for all-round camera work Mr. G. A. Fowkes, writing in "Focus," is that of the reflex type. The chief advantage lies in the fact that the whole of the subject is seen the right way up, and can be focussed to the last moment before exposing. One can therefore use lenses with large apertures and be certain of getting the subject sharply focussed, and as most cameras of this class are fitted with focal-plane shutters, the maximum amount of efficiency is secured in this respect. With a high quality instrument of this class there need be no fear of vibration, owing to mirror flying up out of the way when exposing, the mechanical adjustment being very fine.

### The Oil Process.

Mr. A. J. Anderson, writing of M. Demachy's photographs at R.P.S. in "The Amateur Photographer," says: "Obviously the process is the reverse of gum bichromate, for in gum bichromate the image may be lightened and the high-lights picked out by means of a brush, whereas in this process the shadows and dark tones may be darkened to any extent by repeated application of the ink-charged brush. Hence, in M. Demachy's gum work we may expect to find the effects of accents laid on the high-lights, and in his oil-print work we may expect to find the accents in the dark tones. This exhibition fulfils our expectations, for M. Demachy has entered into the spirit of the medium, and has taken full advantage of the process to pile up dark accents, full of rich gradations. It would be impossible to weigh the merits of the two methods without very careful comparison, but I should imagine that the merits of gum bichromate are similar to the merits of mezzotint, and the merits of the oil process similar to the merits of stipple or etching—that is to say, each its particular artistic quality and value."

### The Oil Process.

Dr. A. R. F. Evershed, writing on "The Oil Pigment Process," "The Photographic News," says: In relation to brush action (1) light quick motion of the brush tends to lift the pigment; (2) conversely to deposit pigment, the stroke should be slow and inclined to rest for a moment on the image.

In relation to pigment consistency (1) a thin fluid pigment gives flat prints, and therefore should be used where the original negative was somewhat hard; (2) a tenacious thick pigment gives contrast cases of over-printed images can be remedied by using such pigment.

In relation to the gelatine condition (1) a moist gelatine takes but little pigment each time the brush strikes it; (2) pigment is readily deposited on a dry image.

During pigmenting various foreign bodies, such as dust, bits of broken hairs from the brushes, etc., will be deposited at the same time as the pigment. These can be removed as they are noticed when the print is quite dry. In the former case a sharply pointed wooden match is the most suitable tool; in the latter, a needle in a handle. But there is one kind of foreign body which should be picked off directly it appears. It is formed apparently by a very fine piece of wool fibre becoming twisted up and matted with pigment and gelatine. It is quite distinct in appearance from anything else, and if allowed to dry becomes difficult to remove, and then only picking off part of the image at the same time. An essential point to note about the process is that there should be no labouring of the pigmenting—the more spontaneous and definite the stroke the better the result. This is particularly the case in figure work. The flesh tones are constantly worked at they will lose all transparency and become dead and flat, hence it is well to bring them out first, and then to modify other parts, so that the whole comes out in the right value. The same principle should be followed in landscape subjects. The principal part should be first worked and then the subordinate portions. Indiscriminate work on the whole image without any definite aim only leads to the worker getting into a hopeless mess, and it is for this reason that I advise the use of a straight or worked-on print as a guide.

### Eikonogen for Warm Tones on Gaslight Paper.

Eikonogen (writes Mr. Laurence Grose in "Photography") is a developer that may be said to have gone out of date somewhat,

it is used comparatively seldom for negatives, and very seldom indeed for bromide or gaslight papers, owing to some fancied unsuitability. It is probably not generally known that it is an excellent developer for warm tones on gaslight papers; and, in fact, it was only after trying almost all other developers for the production of warm tones by direct development that the writer was led to employ eikonogen, which he then found to be more suitable for that purpose than most others, and a very long way indeed in advance of the majority. The developer originally employed was a single solution formula intended for ordinary negative work, and was of the following composition:—Eikonogen, 150 grs.; sodium sulphite (crystals),  $1\frac{1}{2}$  ozs.; potassium carbonate,  $\frac{1}{2}$  oz.; water, to 12 ozs. For rich sepia tones the exposure required for this developer is eight times the normal. The development is well under control, and occupies usually about two minutes. Stock solution, 1 oz.; water, 4 ozs.; potassium bromide solution (10 per cent.), 40 minims. For pure red-brown tones, the exposure in this case is twelve times the normal. The development occupies from two to three minutes. Stock solution, 1 oz.; water, 3 ozs.; potassium bromide solution (10 per cent.), 80 minims. The following developer will be found to give from red-brown to red-chalk tones on most gaslight papers, the exposure being the same as in the last instance. Development takes from three to four minutes to complete. Stock solution, 1 oz.; water, 3 ozs.; potassium bromide solution (10 per cent.), 80 minims; liquid ammonia (.880), 30 minims. Mr. Grose always says that a more serious drawback than loss of density is the loss of quality—that is to say, the degradation of the richness and colour of the print which takes place when it is immersed in the fixing bath. What may once have appeared to be a brilliant red-brown print becomes of a disagreeable orange colour immediately it is placed in the hypo. This can be obviated to a very great extent by the use of an acid fixing bath, such, indeed, as is recommended with almost all gaslight papers. In this the prints are subjected to a somewhat prolonged fixation, during which they will be found partly to regain their lost quality.

#### Press Photography.

The first thing for the press-photographer to do (writes Mr. John Eyraud, in "The Amateur Photographer") is to secure the portrait of the celebrity, and this should also give some intimation as to the nature of the person's work—the *raison d'être* of his notoriety. If, for instance, the person is of literary fame, the picture may be taken in the study in which the famous works are composed. Should the person be the owner of famous race horses, take him amidst paddock surroundings; if an artist, the studio will furnish a suitable environment; but be particular in securing the latter, it will greatly enhance the value of the photograph. Portraiture under such circumstances is by no means easy, for the surroundings are frequently against the production of good likenesses. In indoor portraiture, the photographer should not aim at securing a vast amount of detail, as well as the celebrity; all that is really necessary is a characteristic portrait and one or two accessories, or a suitable environment. A single lens, or the single combination of an anastigmat, will be found most suitable. Aim at getting the utmost sharpness in the features of your sitter, but everything else may be just out of focus, artistically suggested rather than reproduced with striking conspicuousness.

THE LATE PROFESSOR A. S. HERSCHEL, M.A., D.C.L., F.R.S., who died on the 18th inst., was president of the Newcastle and Northern Counties Photographic Association from 1886 to 1888.

THE "AMERICAN ANNUAL OF PHOTOGRAPHY," 1908.—Tennant and Ward, of New York, advise us that they have taken over the publication of the well-known "American Annual of Photography" from its former owners, and are now busy with the preparation of the 1908 volume, which will be edited by John A. Tennant. Good as the "Annual" has been in past years, the new owners desire to make the 1908 issue better than ever—more useful in its information and more attractive in its illustrations. In this they ask the co-operation of all photographers in the shape of articles dealing with photographic experiences or pictorial work of unusual interest. Correspondence contributions for the "Annual" should be addressed to the Editor of the "American Annual," Tennant and Ward, 287, Fourth Avenue, New York. As the book is made up during the summer months, contributors are urged to send their articles or pictures with as little delay as possible.

## New Books.

"Bonnie Scotland" (Part I.). Pp. 22, 13 x 11. Dundee: John Leng and Co., Ltd. 7d.

The "Bonnie Scotland" Portfolio, which is to be completed in twenty parts, will doubtless appeal to the national feeling of all Scotchmen, and is specially designed to provide a souvenir of their native land for the large numbers of its people who have gone, or are going, to seek their fortunes in other countries. Patriotism has always been a predominant feature of the Scottish character, and anything which served to perpetuate the history, traditions, monuments, etc., of their home-land will prove a source of unflinching interest to them. The work is dedicated to Lord Rosebery, and opens with an appreciation by Lord Strathcona. Each part will contain twenty reproductions from the well-known photographs by Valentine and Sons, each illustration being accompanied by brief descriptive notes. Part I. will be on sale on June 28.

"The Wet Collodion Process." By Arthur Payne, F.C.S., F.R.P.S. Pp. 144, 9 x 6. Newcastle-on-Tyne: Mawson and Swan. 3s.

To many, particularly amateurs, the wet process is as dead as the proverbial door nail. Few, probably, have ever seen a wet-plate negative, and fewer still have worked the process. The need, therefore, of a text-book on the process would seem to be minute, but the process is actually in increasing use for its own special branches.

The first chapters are devoted to the essential preliminary considerations such as "elementary theory," "the arrangement of the dark room," "apparatus," and "chemicals and materials." "General manipulations" gives one a very clear, concise description of how to mix the solutions, coat, develop, and fix a plate, and the most difficult operation of all, the collodionising the glass, is illustrated by half-tone blocks of this in operation.

Line, continuous, and half-tone negative making is treated in like simple manner, and throughout practically only one formula for each solution has been given, the author in his preface stating that "other methods and formulæ will probably give equally good results, but those quoted are known to be good." We may also add that they are practically standard formulæ, as recommended for use with Mawson's collodions. This one-formula, one-method system of instruction is undoubtedly the best; multiplicity of formulæ is, like constant change of plates, conducive to failure, whereas with one set formula the beginner knows that it must be his fault, and not that of the materials. It is obvious that the reduction of the number of varying factors must increase the chance of success, and for this reason we think the author is to be commended for his system.

It would seem almost impossible to find anything new to say about wet collodion, but a new process for stripping collodion negatives is described, which we shall practically test this week, and report on.

"Lantern slides and transparencies," "ferrotypes and glass positives," are treated in like clear manner to the negatives.

Another point which strikes us as exceptionally interesting is the method given for making collodion dry plates. These should be of interest not only to the process worker, but also to the transparency worker.

Naturally, bearing in mind the author's well-known little hand-book, "Practical Orthochromatic Photography," we find him giving us instructions how to make collodion plates applicable to the better rendering of colours, and the dyes he suggests are silver eoside and ethyl violet, or ethyl purple 6B for the plates for three-colour work used in conjunction with Von Hübl's liquid filters.

An appendix of recognised formulæ is given, and, above all, there is an excellent index, which really enables one to find things.

To the beginner this book will be of great value, for with a careful attention to the instructions it should be possible for anyone to master the processes described in a very short time. To the expert the chapters on stripping films, collodion dry plates and colour work will specially appeal.

The work is well printed, contains twenty-two illustrations, and is well bound in cloth.

## New Materials.

Eastman Orthochromatic Plates. Made by Kodak, Ltd., Clerkenwell, London, E.C.

It may be remembered that we reviewed the "ordinary" variety of the "Eastman" plate on its appearance on the British market almost exactly two years ago, and we were then able to describe it as a very rapid and most excellent plate. Whatever some say as to the comparative merits of orthochromatic and ordinary plates, the fact that not a single maker can be found who does not manufacture a plate of colour-sensitive properties is sufficient ground for believing that the Kodak Company are wise in adding this variety of emulsion to the hitherto appreciated "Eastman" series of plates. In doing so they have produced a combination of properties which is a distinct step towards the ideal orthochromatic plate of great rapidity and of colour-sensitiveness of a kind which will dispense with a light-filter to cut down the excessive blue sensitiveness to blue of the naturally perverse gelatine emulsion. The plate has, in fact, both great general sensitiveness, and, at the same time, a sensitiveness to yellow compared with that to blue, which is far and away superior to the average erythrosine plate. There has been a general levelling up of quality in this respect during the past year or two, and therefore the new Eastman plate is not a mountain among the molehills, as it would have been, say, three years ago; but its simultaneous great speed and orthochromatic quality still justify us in specially emphasising it as a production of quite special merit. It is, too, somewhat of a departure in orthochromatic plates, on account of its possession of a low "gamma infinity," in conjunction with the above-mentioned qualities, a property which, as will be found in practical work, makes for great softness in gradation and the absence of rapid attainment of great density—rarely a very desirable quality in a plate. Opinions differ, we know, as to the degree to which one may go in thus safeguarding a negative from the tendency to undue hardness, and it must not be forgotten that the hard property of a plate may be counteracted by a long-factor developer, and *vice versa*; a soft working emulsion may be assisted to give greater vigour by the use of a very short-factor developer. The fact, however, remains that in its combination of speed and orthochromatic quality the new "Eastman" plate merits sincere commendation, and the assurance that in both landscape and portrait work it will be found a means of the greatest value towards the production of negatives of high quality.

The following are the results of sensitometric easements made for THE BRITISH JOURNAL OF PHOTOGRAPHY by Dr. S. E. Sheppard:—

Inertia (screened acetylene with H. and D. pyro soda) .....	159
K <sub>γ∞</sub> (measuring the density-giving power of the plate) .....	1.25
γ∞ (velocity-constant of development in standard ferrous oxalate at 20 deg. C.) .....	225
t <sub>γ</sub> (time to reach a gamma of 1 in standard developer) .....	7.1 mins. 7
Blue sensitiveness, yellow sensitiveness = .....	2.8

We have only to add that the plates are marketed by the Kodak Company at the popular prices, based on 1s. per dozen, in the quarter-plate size.

Satin Postcards. Made by John J. Griffin and Sons, Ltd., Kingsway, London, W.C.

The distinctive feature of these new cards is their satin-like surface, which imparts to the prints an extreme richness in the shadows, with good rendering of delicate detail. Another good point is that, the surface being well hardened, they will stand considerable rise in temperature, and there is no sign of blistering and frilling.

They can be obtained coated with Goldona, P.O.P., and bromide emulsions, and these, from our trials, are of the same high quality which we have always associated with other productions of this firm.

YORKSHIRE PHOTOGRAPHIC UNION.—A perusal of the Year-book for 1907-8, just to hand, shows the numerous advantages accruing to those societies who have joined the Union. The list of lecturers contains many well-known names, and the lectures include a wide range of subjects suited to the needs of all classes of photographers. The secretary is Mr. Ezra Clough, 10, Farcliffe Road, Bradford, from whom all particulars may be obtained.

## CATALOGUES AND TRADE NOTICES.

THE CITY SALE AND EXCHANGE have issued a supplementary catalogue containing particulars of the latest additions to their stock of photographic apparatus. Those who already possess the firm's general catalogue would do well to obtain a copy of this supplement, in which space is devoted to various alterations in some of the prices previously published in their large list. Copies may be had on application to the firm at 26 and 28, King's Road, Sloane Square, S.W.; 81, Aldersgate Street; 90 to 94, Fleet Street; or 54, Lime Street, London, E.C.

THE ARMY AND NAVY AUXILIARY CO-OPERATIVE SUPPLY, LTD., have just issued a new edition of their photographic price list, which is comprehensive in character, abundantly illustrated, and contains particulars of practically everything needed by the photographer, be he professional or amateur. In the same building the visitor may buy his apparatus, sit for his portrait, or have his plates and films developed, printed, enlarged, etc., at reasonable charges, and free lessons are given to purchasers of apparatus to the value of £5 and upwards. The photographic showrooms and studios are in Francis Street, Westminster, S.W., from which address a copy of the catalogue may be obtained upon application.

THE "DEFENDER PRIMER" is the name of a little booklet descriptive of the Defender Photo Supply Co.'s specialities. It contains, in addition to a price list, full particulars of the various grades of paper manufactured by the company, together with the most suitable formulae for developing, toning and fixing, and concise instructions for working. Free sample packets of all the firm's productions will be sent on receipt of two penny stamps to cover postage. The London representatives are Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, E.C.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

#### SATURDAY, JUNE 29.

Rugby Photographic Society. Outing to Offchurch.  
Borough Polytechnic Photographic Society. Outing to Hampstead.  
Manchester Amateur Photographic Society. Outing to Liangollen.  
Chelsea and District Photographic Society. Outing to Epping Forest.  
Edmonton and District Photographic Society. Outing to Epping Forest.  
Aberdeen Photo Art Club. Outing to Cove.  
Birmingham Photographic Society. Half-day Excursion to Aston Cantlow.  
Coventry Photographic Club. Outing to Offchurch.  
Handsworth Photographic Society. Excursion to Evesham.

#### SUNDAY, JUNE 30.

North London Photographic Society. Outing to Newgate.

#### MONDAY, JULY 1.

United Stereoscopic Society. "The U.S.S. Exchange Record." A. J. Snow.  
South London Photographic Society. Annual Jumble Sale.  
Bowes Park and District Photographic Society. "Exposure Meters." W. T. Cunningham.

#### TUESDAY, JULY 2.

Sheffield Photographic Society. Annual Meeting.

#### WEDNESDAY, JULY 3.

Devonport Camera Club. Outing to Antony House and Grounds.  
South Suburban Photographic Society. "Bromide Modifications." P. Melett.  
Leeds Camera Club. Evening Excursion—Wigton.  
Edmonton and District Photographic Society. "Titles." Mr. Solly. Competition, June 15 Prints.

PLYMOUTH PHOTOGRAPHIC SOCIETY.—Members and their friend had a very charming trip on the occasion of the last outdoor meeting, when the Secretary, Mr. Wilfrid Grist, had succeeded in getting permission from the Earl of Mount Edgemore for a visit to Cotehele House. This has been the home of the Edgumbe family for centuries, and though it cannot vie with the principal seat of his lordship—Mount Edgumbe, which was to have been the property of the Admiral of the Spanish Armada, had things not gone as they did—yet in antiquarian interest it certainly excels it. There is no such ancient castle, fully occupied at present as a dwelling, in Devon and Cornwall. The party journeyed by rail to the Devonshire border at Bere Alston, a place of Saxon lineage, where, crossing the river Turner has painted more than once—the Tamar—Calstock was reached, not far from which very ancient town is the castle already referred to. The neighbourhood proved to be full of possibilities to photographers, and many plates were exposed. Cotehele and its lovely gardens were subjects to which full justice

could not be done. Within the house the antiquary-photographer found numerous subjects. But the time was too short to do more than enjoy a sight of many tapestries, ancient needlework, arms and armour, and many interesting things. At the invitation of the Vice-presidents, Mr. A. B. Fellowes-Prynn and Mr. W. Clayden, the company enjoyed a strawberry tea at the Ashburton Hotel, followed by a hearty vote of thanks to the hosts. A most agreeable outing was spent, the weather being exceptionally fine.

## Commercial & Legal Intelligence.

**CANVASSING FRAUDS.**—James Smith Dickie and James Campbell, 5, Brown Street, Perth, were cited to appear at Cupar Sheriff Court last week to answer a charge of fraud. Campbell failed to turn up, and Dickie tendered a plea of not guilty. It was alleged that the accused got orders for photographs from people at Ceres, Carnbee, Ialcorno, Freeland, Cameron, and Largoward, the sums received amounting in all to £6 3s.

The Fiscal said the orders were given in the end of March or early in April, and when the charge was lodged he gave Dickie an opportunity of fulfilling his orders. Thereafter Dickie informed him that he had sent off the photographs, but on sending an officer round he found that not a single print had been received by the people. He then cited nineteen witnesses, and when the officer went round with the citations he found that Dickie had been dribbling out prints in this one and the other. The previous day Dickie turned up in court with a large number of prints, and he was evidently making an effort to fulfil his orders. He proposed to adjourn the case for a fortnight to see if he had sent out all the orders. He was very much annoyed with the trouble Dickie had caused.

Dickie said in the end of March two men he had in St. Andrews at their lodging bill unpaid, and the lady of the house stuck to his gaiters and work, therefore it was impossible for him to get the gaiters out. He only got possession of them a few days previously. The Fiscal said that if he had been anxious to execute the orders could have taken a second negative, which would have cost him 1s.

Mr. Alf. E. Grosset said the man emphatically denied the charge of fraud.

Sheriff Armour said there was a certain element of doubt in the case, and he hoped, after being spoken to seriously, he would see the error of his ways and do something to put himself right. The case was a pretty bad complexion, and he proposed to continue it for a fortnight to see if he completed his bargain. If he did so the case would be dropped.

**PHOTOGRAPHING FADED LETTERS.**—In the case of Roberts v. Macoun, a pending action for breach of promise of marriage, the plaintiff appealed from an order of Mr. Justice Walton that certain letters written by the defendant to the plaintiff should be handed to the officer of the Court for the purpose of having photographic copies made of them.

Mr. Macoun, who represented the plaintiff, stated that the defendant, in a "flabby" affidavit, filed in support of the application for the photographic copies, suggested that these letters were not really written by him. When he asked for copies they had the letters lithographed, but the solicitors for the defendant said that they did not do; they wanted photographs of them. The plaintiff's solicitors replied that they would get them photographed and supply copies at 13s. 6d. per single page. There were thirteen letters in all. This offer the defendant's solicitors declined to accept, and they would rather send their own photographer, who would be able to do something to the faded parts that would make them come out clearly in the photographs. That was the very thing the plaintiff did not want.

Mr. Duke, representing the defendant, said it was usual to make an order for the deposit of documents with an officer of the Court when copies were required for the trial. The defendant had done nothing but what he was quite entitled to do.

Mr. Macoun suggested that the letters might never be used at the

trial. To this Mr. Duke replied that if they are not used it would be for the reason that they had been tampered with. The Court dismissed the appeal.

**OFFICE BOYS' RESPONSIBILITIES.**—Allan Downie (18) and Harold Coome (19), both living at Windsor Road, Leyton, were charged on remand at the Guildhall with stealing two £5 Bank of England notes, belonging to their employers, the Rotary Photographic Company (Ltd.), New Union Street, and entrusted to Downie to post. Mr. Coome, father of one of the accused, pleaded for leniency. Alderman Burnett: I can sympathise with you, being a father myself; but I strongly object to a remark you made last time, suggesting that in the City of London it was not right to trust young men of 18 or 19 with a £5 note to place in an envelope. Why, if we could not trust young fellows in our offices to that extent, business could not go on. Coome: I apologise for overstepping the mark. The Alderman expressed his reluctance to convict the accused as thieves, and so blast their careers, upon which the prosecutors withdrew the charge. The Alderman said this was an extremely kind act, and, urging the prisoners to make the most of the opportunity thus given them of starting afresh, let them go.

**CERIO PHOTO PRINTING COMPANY, LTD. (London).**—Issue on June 12 of £650 6 per cent. debentures, part of series created April 19, 1907, to secure £5,500, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £2,700.

**EMPTY CAMERA AND TRIPOD.**—Alfred Roads, aged thirty-four, described as a photographer, was charged with unlawfully obtaining, by means of false pretences, from Kate McStay, divers goods, of the value together of £1 2s., the goods of John Thayer, with intent to defraud, at Fernhurst, on April 13. He pleaded not guilty. Mr. Graham, barrister-at-law, prosecuted, explaining that on the representation that Roads was employed by Messrs. Valentine to take photographs for picture postcards, Mrs. McStay, housekeeper to Mr. Thayer, grocer, gave him board and lodging. Mrs. McStay said that during tea-time the first day prisoner said he had a pension of 35s. a week. At the end of the week he said he could not pay then, but would do so after a fortnight. A bill for 24s. was given him at the end of the fortnight, but as he again said he could not pay, the police were informed. Mr. E. H. Harrison, manager to Messrs. Valentine, said prisoner had not been employed by them in any way. P.C. Barnes said that when he arrested prisoner he had an empty camera and tripod, and several pawn-tickets. Roads gave evidence on oath, and in the course of a long tale told the court that a doctor in Warwickshire owed him £8 for repairing a clock. He denied saying that he was employed by Valentine; and stated that there should be eleven exposed plates with the camera. He got the camera about a year ago at Timothy White's at Petersfield. P.C. Barnes, recalled, now produced a bag containing plates. The jury returned a verdict of guilty. Prisoner admitted a conviction for felony at Aylesbury in 1905. A constable said that at Aylesbury Quarter Sessions on April 3, 1905, Roads had twelve months' hard labour for stealing three photographs and a prayer-book; on that occasion a second charge of false pretences was not proceeded with. The Chairman said it was very hard upon people of the position of Thayer that they should lose their money, because Thayer had none to spare. —Four calendar months' hard labour.

**CLAIM FOR WRONGFUL DISMISSAL.**—In the Lord Chief Justice's Court, before a special jury, on 25th inst., an action for wrongful dismissal was brought by J. R. Sykes against The Charles Urban Trading Company, of Rupert Street. Verdict was given for the plaintiff with damages £120 and costs, stay being refused.

**PHOTOGRAPHIC RIGHTS.**—One of the most interesting actions tried at the Cumberland Assizes at Carlisle on Saturday was that brought by Frederick Nainby, photographer, Cocker-mouth, against Messrs. Beaty, printers, Carlisle, for the alleged infringement of the copyright in the photograph of Captain Guest, who contested the Cocker-mouth Division against Sir J. S. Randles at the bye-election last year, occasioned by the death of Sir Wilfrid Lawson.

The photograph, according to the statements of the plaintiff's counsel and witnesses, was taken on July 11 of last year, when Captain Guest was asked to have his photograph taken for reproduction in

newspaper, and he went to the plaintiff's studio at Cockermouth for that purpose.

Subsequently the defendants, who were printers in Carlisle, wrote for permission to reproduce the photograph on badges and postcards, but this permission was not granted. However, they took it, and reproduced it on picture postcards, which were sold.

Captain Guest gave evidence for the defence. He said he wanted to have his photograph taken for election purposes, and blocks were mentioned, and he fully expected he would have had to pay for the photograph, as he had gone through the same experience when a candidate in the Kingswinford Division, and paid for his photo there. He made no arrangements with anyone that deprived him of the copyright in the photo taken by Mr. Nainby.

Mr. Justice Channell said that, *prima facie*, the copyright was in the person who took a photograph, but there was a proviso that when a negative was taken for or on behalf of any other person for a good or valuable consideration then the photographer did not secure the copyright without bargaining for it. In this case no bargain was made; the thing was done in a hurry, like most things at election times. He must hold therefore that the copyright was in the plaintiff, and that the case did not come within the proviso to which he had referred.

The plaintiff was the author of the photograph. No penalties were claimed by the plaintiff, who only sought damages, and judgment would be for the plaintiff for £5 damages.

**SINGULAR CLAIM AGAINST A BIOSCOPE OPERATOR.**—At the Clerkenwell County Court, before his Honour Judge Edge, Messrs. Wm. Jelks & Sons, furnishers, of Holloway Road, sued Humbert Guiseppe Cura, bioscope exhibitor, of Cascart Road, Balham Hill, in respect of chairs supplied.

Mr. Solley, for the plaintiff firm, said they supplied sixty chairs to defendant under a hiring system, by which defendant agreed to keep them in good condition, damage by fire included. There had been a fire at defendant's premises, and as a result the chairs were damaged more or less. He had the goods in March, and agreed to pay £1 deposit and 3s. 6d. per week, but beyond the deposit plaintiffs had only received one 2s. 6d. Defendant was insured, but he had excluded the chairs. He (Mr. Solley) now asked for judgment for the total amount, so that he could take proceedings.

Defendant said that all that was due on the day when the summons was issued was 25s. 6d. He contended that plaintiffs could only claim under the hiring agreement. He told Mr. Solley that the goods were insured, and immediately his claim was settled the plaintiffs would be paid.

The Deputy Judge: Then are these goods insured?

The Defendant: Yes.

Mr. Solley said he wrote to the insurance company, pointing out that amongst the goods burnt or damaged at defendant's premises were sixty chairs belonging to the plaintiffs. The letter said: "We must request you to withhold payment of any money to Mr. Cura or his assignee, pending a settlement of our claim for £12 7s. 6d., being the value of the goods mentioned above." The insurance company replied that they had forwarded the claim to their assessor for his attention. He (witness) had seen the assessor, who said that the goods in question were not included in the policy.

Defendant: My insurance claim is under arbitration, and that will prove that the goods are insured. The insurance company are repudiating the claim if they can.

The Deputy Judge: Then I understand that you admit your liability subject to your getting the money from the insurance company?—I admit my liability up to the date of the payments due.

Not the full amount?—No.

The Deputy Judge: It seems that the issue for me to decide is whether he has insured these things or not?

Mr. Solley: I have seen the clause. I say emphatically that he had not insured them.

Defendant: He is telling a lie—one of the biggest he can utter.

The Deputy Judge: Then you must bring your policy. That will speak for itself.

Defendant: I only owed them 25s. 6d. They have sued me for the whole amount. As soon as my claim is settled they will be paid.

Replying to the Deputy Judge, defendant expressed his willingness to give plaintiffs every facility for attending the arbitration. He would send them notice of it by registered letter.

The case was adjourned, costs being reserved.

## News and Notes.

DR. IRA REMSEN, President of John Hopkins University (say "The Scientific American") is authority for the statement that Sir William Ramsay has discovered a method of making artificial copper, and that the great discovery will be made known to science when Sir William will read a paper on the subject before the Royal Chemical Society of Great Britain. Professor Remsen has a private letter from the famous Englishman, stating that Sir William has succeeded in accomplishing what no other chemist has ever been able to do—the segregation of one element from another and the production of copper by the synthetic or combining process from the elements sodium, lithium, and potassium. A combination of these elements when treated with radium vapour gives as a product copper sulphate, which is readily "broken down" into copper. Such is the substance of his experiments. The discovery, if true, is of so startling a nature that we must withhold judgment until the publication of Sir William Ramsay's paper. This brief preliminary note is published merely for what it is worth, and not as a verification.

LIMERICKS are so exceedingly popular just now that it might be useful to point out to our readers that Limericks on the subject of the "Tikka" would be eligible for the "Tikka" Title Competition. "Tikka" postcards may be obtained from any dealers in photographic materials, and with one of the postcards and a little ingenuity there should be no difficulty whatever in earning one of the twelve prizes of two guineas that Houghtons are offering in this competition.

THE WINNER of the three-guinea Holborn Hex hand camera in the "Ensign" Roll Film Monthly Competition is Mr. R. Dixey, of Waterloo House, Ipswich. The successful photograph represents a street scene on a wet day, and, although rain is falling heavily, and umbrellas are up in all directions, the negative is fully exposed and full of delicate detail.

LUXURY AFLOAT.—On Saturday last a large gathering of representatives of the Press had a very enjoyable cruise from Southampton round the Isle of Wight, on the Royal Mail Steam Packet Company's new twin-screw mail steamer, "Avon." This vessel is the fourth of the well-known "A" class of steamers which the company have within the last two years, placed on their South American mail service. The dimensions of the vessel are: Length, 535ft.; breadth 62ft.; with a gross register of more than 11,000 tons. Although the "Avon" is designed to carry a large quantity of cargo, the passenger accommodation is on a most sumptuous scale. A point deserving particular mention is that the state rooms are on deck, there being no rooms below the upper deck, an improvement that should appeal strongly to intending voyagers. Single berth state rooms are also a special feature, thus enabling travellers to enjoy the same privacy and comfort on this "floating hotel" as in hotels ashore. Among other features of the "Avon" are the social hall and lounge, situated on the promenade deck, also smoke rooms, which are all beautifully decorated and mechanically ventilated with electric fans. Those devoted to photography will also find a dark room and all its concomitant appliances furnished for their use. The "Avon" was launched at Belfast on March 2 last, and starts on her maiden voyage to-day.

A WATCHMAN at the Kodak Works, Harrow, whilst talking with some lads employed there, pulled his handkerchief from his pocket at the same time jerking out a revolver. The weapon fired, and seriously injured a lad named Spencer, who was taken to the hospital in a precarious condition.

THE LONDON STEREOSCOPIC COMPANY, LTD., have enlarged and improved their well-known premises at 54, Cheapside. The studio, in addition to being built at a height which makes it surprisingly light even on a dull day, has also a powerful and ingeniously arranged electric installation, so that would-be sitters may entirely disregard weather conditions. The company also undertakes all kinds of photographic work for the trade, as well as coloured enlargements.

THE HEALTH RESORTS DEVELOPMENT ASSOCIATION, of 29, John Street, Bedford Row, London, W.C., sends us copies of booklets published by them for the Town Councils of Dunbar, Inverness, and North Berwick. These little guide books, which are edited by Mr. George W. May, contain a quantity of useful information in a small space, and the numerous illustrations should convey to the intending

for a general idea of the scenery and objects of interest which it him. Copies may be obtained free by sending a postcard to the Town Clerk at either of the above-mentioned places.

**SOCIETY OF ARTS.**—The society's conversazione will be held in the central portion of the gardens of the Royal Botanic Society, Inner Circle, Regent's Park, on July 9, from 9 to 12 p.m. The conservatory club house will be open to visitors.

**PHOTOGRAPHERS AT NARBONNE**, in common with the inhabitants generally, are having a rough time. The representatives of the "Littérature" and "Monde Illustré" a few days ago had their cameras snatched from them and destroyed, the former being in serious danger of losing his life also; whilst the representative of the "Daily Mirror" was threatened with immersion in the canal.

**ESSEX PHOTOGRAPHIC POSTAL CLUB.**—Owing to the death of the late Mr. T. Perkins, Mr. Hermann Lea has been appointed secretary of the above club, and all communications should now be addressed to him at Var Trees, Clyffe, Dorchester.

**THE BRISTOL PHOTOGRAPHIC CLUB** have arranged to hold their annual exhibition during the first week of October next, in the central suite of rooms of the Bristol Academy of Fine Arts. Their year's exhibition was a great success, both from the pictorial and financial point of view, and the financial results to the club and to exhibitors were most satisfactory. This year the committee are making several important alterations in the classes and awards, and will, in their opinion, benefit the cause of pictorial photography. The hon. exhibition secretary is Mr. J. S. Guthrie, 23, Clifton Square, Clifton, the same as last year.

**NORTHERN PHOTOGRAPHIC EXHIBITION.**—At a meeting of the committee of the above, held in Liverpool, June 24, it was resolved in view of the official communication from the Hon. Sec. of the Leeds Camera Club, announcing its inability to carry out the act to hold the "Northern" at Leeds in 1908, this executive committee hereby relieves the Leeds Camera Club of all its obligations relating to the N. P. E. It was also resolved "That the next exhibition" be held in Manchester in 1909."

**CUMBERLAND AND CHESHIRE PHOTOGRAPHIC UNION.**—The second annual excursion of the above union took place on the 15th inst., a party, to the number of about a hundred, visited Barrow-in-Furness Abbey, and were afterwards entertained to tea by Mr. F. J. Ramsden, President of the Barrow Naturalists' Field Club.

**CHANGE OF ADDRESS.**—Mr. J. C. Hughes, formerly of 14, Edith Street, West Kensington, has now removed to 95, Gloucester Road, Kensington, S.W.

**EXHIBITION of the latest novelties in photographic apparatus and materials** will be held from July 1 to 13 at the photographic department of Bishop's Pure Drug Co., 466, Holloway Road, London, N. Demonstrations of new processes will be given daily, as well as admission to the exhibition, will be free to all.

**EMPIRE PICTURES.**—Nearly 50,000 pictures a day will be shown at the great exhibition which is to be held in the Royal Horticultural Gardens, Westminster, on July 18, 19, and 20, on behalf of the Empire Education Fund and Lady Dudley's scheme. The Princess of Wales has taken the deepest interest in these proposals for Empire education, and has sent a donation in response to the Countess of Dudley's appeal for £5,000 to despatch artists and photographers to the various colonies to obtain the best possible pictures in these British dominions for use in English elementary and secondary schools. Subsequently Lord Mayor, at the urgent request of an influential committee, has donated the Empire Education Fund. The exhibition is under the management of the Countess of Dudley, Mrs. Humphry Ward, the Duke of Ormonde, the Earl of Drogheda, Lord Meath, Earl of Devon, Sir Bartle Frere, Sir Richard Solomon, and the Lord Mayor. Agents-General are co-operating with the organisers of the exhibition—who include Mr. Allen Stoneham and the executive of the Empire Education Fund—and have lent a magnificent collection of pictures, together with products and curios of their countries. The British South Africa Company will also send specimens of the natural products of Rhodesia, and another company have lent, quite at cost, their powerful electrical automatic lanterns, which will

work throughout the three days. The pictures are photographic monochromes, and are the finest products of that art. They illustrate every phase of Colonial life, step by step, from the outposts of the Empire to the great commercial centres.

**DEATH OF MR. ROBERT PRINGLE.**—We regret to record the death, on the 23rd inst., of Mr. Robert Pringle, of the well-known firm of Messrs. Pringle and Sons, of Clerkenwell Road, E.C.

**THE OXFORD PAGEANT** will take place from June 27 to 29, and July 1 to 3, and gives promise of being one of the finest historical pageants ever produced. The Gaumont Company are holders by appointment of sole cinematograph rights in its reproduction, and the films will be obtainable only from them at Chrono House, 5 and 6, Sherwood Street, Piccadilly, London, W.

## Correspondence.

“Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.”

“We do not undertake responsibility for the opinions expressed by our correspondents.”

### FLUORESCENCE IN OPTICAL SENSITISING.

To the Editors.

Gentlemen,—I am much obliged to Dr. Mees for calling attention to one point in Dr. Stark's experiments, which I did not take into consideration, and which seems to me to be a still stronger argument against accepting the existence of “latent fluorescence” without further proof.

I have not used Heraeus's mercury lamp, but with the ordinary Cooper-Hewitt lamp the photochemical activity of the blue and violet rays, which may practically be considered as  $\lambda$  3390, 3654, 3663, 3925, 4048, 4062, 4078, 4347, 4358, and 4916, is so great that in shifting the dark slide in a diffraction grating spectrograph so as to obtain successive spectra, the total shift being three-quarters of an inch and the total time of movement about 15 seconds, the whole of these lines are recorded whilst the plate was moving, the slit width being 0.075 millimetres and the plate used being a panchromatic H. and D. speed 170. If then these lines in the mercury spectrum are so photochemically active, I think that with forty minutes' exposure, as given by Dr. Stark, one might obtain practically the continuous stripe which I described as being seen with daylight.

Dr. Mees's argument might, I think, apply were the light, as he says, “monochromatic,” but it is not, and the further you go into the ultra-violet the richer the mercury vapour is in rays. This being granted, I fail to see why my suggestion, and it is only that, as to the polarisation of small particles of these short wave-lengths should not produce the effect which Stark has described.

Unfortunately, though Stark mentions that he uses a quartz spectrograph, he gives one not the slightest indication of the dispersion obtained, and with a low dispersion I think that the above-mentioned wave-lengths would be practically continuous.

Further, Dr. Mees admits the possibility of the correctness of my surmise as to the prismatic effect of the meniscus edge; then I have proved the very powerful action of the blue and violet rays. Why should not this come into play in “forty minutes' exposure?”

I am quite prepared to admit I am wrong when proved to be, but I still consider that confirmation of Stark's experiments are required.

One minor difficulty is that no indication is given of the wave-lengths of the light obtained, and this apparently differs in different lamps; at least, Arons has given some red and orange lines as existent in his lamp, which I have been unable to obtain. The subject is also complicated by the fact that in the Arons and, I believe, the Heraeus lamps, both electrodes are covered with mercury continually, whereas with the Cooper-Hewitt one is bare, and I have certainly obtained both water-vapour and iron lines in addition to the mercury. This being the case then, it is quite possible that other lines may appear between those I have enumerated above, which

are only the principal ones, and undoubtedly due to mercury. Mercury has so many spectra that in deciding a question of this kind it is absolutely essential to have an accurate reading of the lines. —I remain, yours faithfully, E. J. WALL.

#### WANTED; A POCKET REFLEX.

To the Editors.

Gentlemen,—I have read with interest the many articles that have of late appeared in your Journal, *re* the uses of the reflex camera. Two of the many advantages of the reflex are (1) correct focussing on rapidly moving objects, and (2) pictorial composition.

Now, those are the two most important features which we press and postcard operators require. But, unfortunately, we have to wait for ideas in each class of work, which compels us to use an ever-ready camera that will slip into the ordinary pocket, instead of carrying the present bulky reflex in the hand, under the eyes of the ever curious public.—Yours faithfully, W. JOHNSON.

No. 1, Second Street,  
Gateshead-on-Tyne.

#### REFLEX CAMERAS.

To the Editors.

Gentleman,—Like the man in "Punch" who gave a testimonial to a soap maker, I have never used a reflex camera, but should very much like to. Many of my wealthy friends have from time to time allowed me to peep into the inward parts of these desirable and costly instruments, some of my friends have even allowed me to take these cameras out for an hour or two; but in every case the negatives I have made showed that I had not held the camera quite level.

My excuse for troubling you with this, Sirs, is that it might be useful to some who use these cameras, whose eyes are too firmly fixed in their heads to allow one eye to look to one side of the ground glass while the other looks to the other side, if a circular spirit level, with a glass bottom, as well as a glass top, could be fixed on to the ground glass. A friend of mine tried to get such a level but could not.—Yours obediently, J. M. SUTCLIFFE.

Whitby in Yorkshire.

June 22, 1907.

#### TO PROFESSIONAL PHOTOGRAPHERS.

To the Editors.

Gentlemen,—I shall be glad if you will kindly allow me to draw the attention of my professional brethren to the following paragraph from the Hereford Convention programme:—

"PROFESSIONAL PHOTOGRAPHY.—A desire having been expressed that professional photographers attending the Convention should have opportunities afforded them for informal chats on business matters, a special room at the Town Hall will be provided for this purpose on Thursday and Friday evenings, July 18 and 19, at seven o'clock."

Now, gentlemen, the universal cry seems to be: "Times are hard." Come and let us reason together, and see if we cannot improve matters.—Yours truly, F. A. BRIDGE, Hon. Sec. and Treas.

East Lodge, Dalston Lane, London.

#### THE EFFICIENCY OF IRIS SHUTTERS.

To the Editors.

Gentlemen,—I am glad to see that Mr. Welborne Piper has pointed out the error made by Mr. Anderson with regard to this excellent form of shutter, but we can go even further than Mr. Welborne Piper has gone. Assuming the conditions as to uniform speed, etc., as assumed by Mr. Anderson and Mr. Piper, if the area of the opening is plotted against the time and a curve drawn, it will be seen that at the beginning and end of the exposure the area (or exposure effect) is for a considerable distance so small as to be negligible. This applies also to the blind shutter in front or behind the lens, but to a much less extent. This alone would probably raise the practical efficiency of the iris shutter to that of the blind shutter, with its square opening. There is, however, still another point. If, for

purposes of depth of definition or marginal definition, the lens has been stopped down, one may safely use a larger aperture with an iris shutter than with any other form of shutter, because the full aperture is effective for only a part of the time. For this reason a cheap lens with an iris shutter may perform as well, at equal apertures, as an anastigmat with a blind shutter. Taking all the facts into consideration, I think there can be little doubt that, in ordinary practice, an iris shutter gives a greater practical efficiency than the ordinary blind shutter at the lens in almost all cases. If an iris shutter could get to work satisfactorily at, say, the five hundredth of a second, would probably nearly equal, or even surpass, the ordinary blind shutter in efficiency. But, of course, this would depend on the width of slit of the focal plane shutter, its distance from the plate, and the aperture of the lens.—Yours, etc.,

CHAPMAN JONES

## Answers to Correspondents.

\* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C." Inattention to this ensures delay.

\* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

\* Communications relating to Advertisements, and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.

\* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, &c. Two unmounted copies of each photograph must be sent with fee.

#### PHOTOGRAPHS REGISTERED:—

- E. Hamilton-Toovey, 35, Royal Parade, Jersey. Three Photographs:—Comb Bands (Regimental and Drum and Fife) of the First East Surrey Regiment and Fife Band, Regimental Band.
- F. Newell, Stour View, Colchester Road, Manningtree, Essex. Four Photographs:—View of Mistley Towers, Essex. Bird's-eye View of Manningtree from the Windmill Tower. View of Top of South Street, Manningtree, shown Wesleyan Chapel. West Street, Alresford, Hants.
- R. S. Henderson, 35, Fargate, Sheffield. Three Photographs of the Rev. Geo. Ommamey, M.A.
- F. Coghan, 81, Carlisle Road, Londonderry. Two Photographs of the Right Dr. McHugh, F.F.V.G., Strabane.
- G. F. White, 57, Hilderthorpe Road, Bridlington. Photograph of Mrs. Wallis and Mrs. Bulloch, Bathing Van Attendants, Bridlington.
- D. S. Taylor, 7, Gowan Street, Arbroath, N.B. Photograph of Arbroath Harbour from an Old Engraving.

#### DRAWING REGISTERED:—

- J. Grice, 4, Dax's Row, Welshpool, Montgomery. Drawing entitled, "I Wish Some More, I Can't Eat It."

ANXIOUS.—A great deal depends upon whether the firm gave you an order to take "negatives" for them, or merely ordered prints, and whether you have invoiced them as "negatives" or "prints" only. In the face of what you state, the negatives are yours, and cannot be claimed by the firm. The price may be entirely a matter of arrangement between yourselves, and should advise you to take into consideration the possibility of future work.

E. W. T. F.—There are several devices of the kind on the market at the present time, and you would find them illustrated in the list of any large dealer such as Fallowfield, Houghton, &c. We can, of course, if you like to send us up sketch or photograph of the apparatus itself, tell you whether there is anything like it. You can obtain provisional protection for 20s., and have to up a form, obtainable from the Patent Office. We should

ise you to let us see it first, we will then tell you our opinion and write you privately.

LEWIN.—1. Yes, any flashlight apparatus can be used in open air. Write to the firm from whom you got the camera, and they would advise you. 2. Do you want to enlarge by day or artificial light? Write again, letting us know this, the full extension of your camera. 3. We should strongly advise you to see the exhibition of Reflex cameras now open at the Crystal Palace. This is the most satisfactory type for your special purpose. We are obliged for the information given, but are afraid cannot help, as it is a matter which rests entirely in the hands of the employees.

BACKED PLATES.—1. Will you kindly let me know enough of your paper how to develop backed plates; also do you back the backing off after developing, and how to do the same? Can you buy paper to back the plates yourself?—J. W. WILKINSON.

BACKED PLATES.—1. Backed plates are developed in precisely the same way as ordinary plates, and the backing may be removed before or after development, this being entirely a matter of taste, and to a certain extent dependent on the backing. Personally, we remove the backing after development is complete, by placing the plate under running tap and rubbing the backing off with a tuft of cotton wool. 2. Almost all dealers keep an adhesive red backing paper which is wetted and applied to the back of the plate, or there are several commercial pastes and liquids which can be used with sponge or brush.

WILKINSON.—Your test is not quite fair. Try a sheet of newspaper perfectly flat, about ten times the focus of the lens from the camera. See that your camera is perfectly level and parallel to the paper, and focus on ground glass in the dark. If then you get want of definition, write the makers.

DEVELOPER.—1. Having some trouble recently with oxidation of pyro solution, I determined to give the formula mentioned on p. 763 of the "B.J.P." for 1906 a trial, and, so far, satisfactory results. I notice, however, that potassium hyposulphite is omitted, and should be glad to know if this is indeed, on account of the additional restraining powers of the hyposulphite. Development is certainly slower with your formula, not so slow as to be a serious drawback, and the cleanliness of the pyro, and the ability to use it several times over, are its advantages. 2. Is pyro "of" pyroxal a misprint in the formula given on the page mentioned? I think it should be "of" instead of "of."—H. S.

The bromide was intentionally omitted, not because of the restraining action of the sulphite, but because we do not consider that bromide is necessary with the majority of plates. Potassium hyposulphite can always be added if desired, but it must not be forgotten that it slows the plate. Our experience is that, given anything like correct development, there is no need for bromide. It should read "pyro or pyroxal."

E.—The white spots on the portrait are undoubtedly air which have clung tenaciously to the gelatine. It is always well to pass a piece of clean cotton wool, well wetted with developer, over the film immediately after applying the developer, so as to make sure of breaking any air bells. The marks on the church negative are due to not rocking the dish during development, and are known as "mottling." Neither can anything be done with the "bike."

TRANSPARENCIES.—Can you tell me how to paint transparencies with aniline dyes, so as to avoid sharp outlines?—D. HALES.

There are two principal methods, one in which the plate is developed in a wet state and the dyes merely applied in aqueous solution, and the other in which strong solution of the dye in an arabic solution is applied to the dry film in drops and the film made to coalesce. The easiest method is undoubtedly the first, but there is a danger of the outlines showing, as weak solutions are used and depth of colour obtained by successive washes. The dyes to use may be new Victoria Blue, water soluble; brilliant acid green G; rose bengal; tartrazine and crystal violet 6B. Make these up into strong

stock solutions, then break them down with water and add a little glycerine before applying. Work by artificial light, and remember that the colours appear rather more brilliant in the lantern. The second process is a little more difficult, as strong solutions of the dyes have to be made and mixed with strong gum arabic solution and applied in very minute dots, and then made to run together, and each colour must be absolutely dry before another is applied.

CEMENTING FILMS.—I want to cement the edges of two films together, and fail to do this without the line showing. What is the general method?—FILMS.

The usual method is to shave both films down a little where they are intended to overlap. This can easily be done with a fairly sharp knife, using it very nearly at right angles to the film. Then wet the shaved edges with either a thin solution of celluloid in amylacetate, or damp them with acetone and amylacetate in equal parts, and press into contact with a warm iron.

H. L. V.—It is utterly impossible for us to give a decision in the matter. It seems to us to be, from your letter, a question of absolutely contradictory statements, which can only be adjusted by arbitration. If both sides will agree to submit it to arbitration, this seems to us to be the happiest way out of the difficulty.

GEO. PARDON.—Boil for ten minutes, and do not allow the temperature to sink below 120 deg. Fahr.

SEPIA POSTCARDS.—I have seen a formula for a sepia process, which can be used for sensitising postcards, etc., in one solution. Can you give me the same?—P. C.

Probably the following might answer:—

1. Ferric ammonium citrate (green) .....	110 grs.
Distilled water .....	1 oz.
2. Tartaric acid .....	18 grs.
Distilled water .....	1 oz.
3. Silver nitrate .....	45 grs.
Distilled water .....	1 oz.
4. Gelatine .....	30 grs.
Distilled water .....	1 oz.

Soak the gelatine in water till soft, and melt on a water bath, then add Nos. 1 and 2, and finally No. 3, in very small quantities, stirring all the time. The image is printed out and fixed in a 1:50 hypo. There are many other formulæ, but this is satisfactory.

INTENSIFYING PLATINOTYPES.—Is it possible to intensify weak platinotype prints, which are slightly under-printed?—PRINTER.

There are many formulæ, but the most satisfactory is:—

1. Sodium formate .....	45 grs.
Water .....	1 oz.
2. Platinum perchloride .....	10 grs.
Water .....	1 oz.

Add 15 minims of each to 2 ozs. of water and apply to the print.

N. A. R.—It is impossible for us to give any decision on this point without seeing the apparatus. If you like to make an appointment we shall be pleased to examine it and tell you as much as we can as to what has been done in this particular direction.

VARNISHING PLATINOTYPES.—I have seen somewhere a method of varnishing platinotypes mentioned in your journal, but am unable to find it. Can you tell me where it is or repeat?—TONBRIDGE.

The formula has been repeatedly given in the Journal, or will be found on p. 811 of the "Almanac" for 1907. It is:—

Sandarac .....	2 ozs.
Benzole .....	8 ozs.
Acetone .....	8 ozs.
Absolute alcohol .....	4 ozs.

Allow to stand with occasional agitation till dissolved, then allow to settle or filter, and brush over the print, if necessary giving two or three coats.

DEVELOPER FOR BROMIDES.—Will you kindly tell me, in your next issue of the "B.J.," the best developer to use for bromides, that are to be toned sepia with sodium sulphide, "Almanac" formulæ, 1907? The reason I ask is this. That enlargements I have made myself and developed with amidol or metol hydroquinone are not

warm enough, and have a flat appearance; whereas I received a print to-day from a firm of enlargers and toned it with some others that I had made myself. Their print made a splendid sepia, while my prints were very poor. I ought to say that the prints were quite right before toning.—*EN AVANT.*

The best developer is, we think, ferrous oxalate, the formula for which will be found on p. 953 of the "Almanac" for 1907.

**INK STAINS.**—I have had the misfortune to spill some ink on the mount of a much prized photo. I will feel very grateful indeed if you will inform me, through the columns of "B.J.P.," of a solution that will effectively remove it.—*J. B. O.*

The best thing would be to obtain a small quantity of what is generally called salts of lemon or the acid oxalate of potash from any chemist and sprinkle over the ink spot, and then drop a drop or two of water on it, repeating the application till it removes it. If the stain is stubborn it might be worth while to try the effect of a little chloride of lime, applied in strong solution, and then put a drop of vinegar on it.

**SOLAR ENLARGEMENTS.**—Can you tell me where to find the formula for making cheap solar enlargements?—*ENLARGER.*

A formula is given on p. 821 of the "Almanac" for 1907, and several on p. 270 of the "B.J." for January 11, 1907.

**PHOTOGRAPHS ON WATCH CASES.**—Can you please inform me how to secure a photograph on the inside of a watch case? I have heard of a method whereby the image is transferred from a C.C. print directly on to the metal.—*A. W. S.*

We must refer you to an article on page 451 of our volume for 1901, as the space in this column is far too limited to give such information as would be of real use to one who has no practical knowledge on the subject. The article mentioned gives full working details for producing photographs on watch cases and metals generally.

**DOUBTFUL VALIDITY.**—I am much obliged for your reply in the Journal last week to my question *re* agreement. I now send you a copy of the agreement itself, and should be glad if you would express your opinion upon it. I thought you would like to see the copy of agreement. You will understand my position. I am a married man, with a family of three, and if I am not permitted to work for another person I take it I shall be compelled to leave the town or give up my profession, which I had eighteen years' experience in.—*DOUBTFUL.*

Our opinion is that the agreement is of no value whatever. There seems to be no equity in it. It does not appear that you received any consideration whatever for signing it, and there is no time limit to it, which is usual in such cases. Furthermore, the twenty mile radius would, probably, be considered by the County Court an undue restriction of trade, which is against public policy. If you refer to our issue for August 3 last year, page 603, you will find an article which goes pretty fully into the subject of "Photographers' and Assistants' Agreements." However, as we said last week, you had better consult a solicitor on the matter, so as to be on the safe side.

**ENLARGING LENS.**—I have been using the lens from an optical lantern for enlarging, but am unable to obtain sharp definition, particularly towards the edges. Is it possible to improve the lens in any way, or must I get an anastigmat?—*P. FIELDER.*

It is quite possible that the lantern lens might be improved by slightly separating the back components a little more. Frequently this gets over the trouble. They are now separated by a narrow metal ring. Remove this, and cut some strips of cardboard slightly wider, and place in between the lens, and then practically test after each ring is placed in position.

**B. H.**—The negatives you send are not damaged. It is obvious that they have been varnished, and have been splashed with water, which always causes the peculiar concentric rings. Soak in methylated spirit, with a little ammonia, and rub with a tuft of cotton wool.

**F. J. T.**—(1) As the Act does not come into force till July 1, we hardly see that any claim can hold water. It is a matter for a solicitor. (2) We regret that we must decline. Our rule on this point is strict. (3) The paper was made in Germany, and even there now it has been dropped. (4) Send letter and we will forward it.

**J. T. CLARKE.**—There is no objection to having glass on both. You could easily block out the south with opaque curtains you did not want to use it, and it would be an advantage able to have it at times.

**KALLITYPE PROCESS.**—Will you kindly give me complete instructions for working the Kallitype process?—*IRON.*

This is rather more than we care to undertake, and we suggest that your best plan would be to obtain No. 47 "Photo Miniature," which deals entirely with this subject. Barn and Ward, 6, Farrington Avenue, E.C., are the publishers.

**SUPPLEMENTARY LENSES.**—I want very occasionally to use a very much shorter focal length, and also one of a very longer focal length, than any that I possess. Is it possible to hire a lens or convert my existing lenses into long and focus ones?—*OPTIC.*

Several firms, such as the City Sale and Exchange, Sand Hunter, etc., loan lenses out, or you can obtain supplementary lenses, which will temporarily convert your lens into short long focus lenses. Supplementary lenses are sold by near dealers.

**J. BARNES.**—We cannot undertake to answer letters by post, we receive fees for doing so. A formula is given on p. 821 of the "Almanac" for 1907, for simultaneous developing and but this is not going to save you time, as the process is slow. Considering that you can develop a bromide print in less than two minutes and fix in about five, and if you use the calcium fixing bath you can wash in hot water and complete whole operation in about ten minutes, we fail to see where advantage would lie in simultaneous development and fixing. There would be no objection to showing your customer enlargement in the hypo dish, and after about half a minute immersion, the light would have no practical effect on it.

**G. R. BIRMINGHAM.**—We do not know where Mr. Harrington is likely to stay, and he will not arrive here till about July 12, probably we shall hear.

**M. MACKINSON.**—If you look through the small advertisement will find several lights advertised. Your best plan would be to write for details and choose yourself, for you can tell us more than we can what would suit you. If, after having received details, you like to write again, we will do what we can for you.

**J. HARRIS.**—Some are hairs or threads of cloth, others are uncleanly actual dirt, and some iron or other metallic particles.

**PHOTOGRAPHY AND THE COLLECTOR.**—It is presumable that the majority of collectors, whatever their particular branch of that hobby may be, are also photographers, as the camera provides them with special facilities for obtaining records of objects of interest in their collections. With a view to further stimulating such interest, the proprietors of "Collecting" are offering a weekly prize of half a guinea to the reader who sends in the photograph accompanied by the most interesting note of any article likely to prove of interest to the readers of that paper. All photographs must be accompanied by the competition coupon, published in the pages of the journal, and should reach the offices of "Collecting" in Grafton Street on Tuesday mornings.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received in the usual manner, but the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Exhibition of Reflex Cameras closes to-morrow, July 6. This is a phenomenal success, and those of our country readers who have been able to visit it and are going to the Photographic Exhibition will have an opportunity of seeing the majority of the exhibits there.

E. W. Foxlee, in his series of articles on the "Collodion Process," deals this week with the preparation of the collodion and its use. (P. 500.)

Printing negatives is to many a fearsome operation. It is proved, however, that, when properly set about, it is very simple. (P. 498.)

One of the strongest pleas for tank development yet made is advanced by Mr. C. H. Claudy. He proves that it is cheaper, saves labour, and temper, and gives better results than the ordinary method. (P. 502.)

Use of Sunday trading, with a somewhat amusing and ingenious illustration, appears this week. (P. 508.)

## "COLOUR-PHOTOGRAPHY" SUPPLEMENT.

Lumière Autochrome plates are reviewed after practical tests.

Instructions for the use of the above plates are given in the supplement. (P. 51.)

Kenneth Mees deals with the printing of positives from Autochrome and linear filter plates. (P. 49.)

E. J. Wall suggests the use of panchromatic flashlights for work in the evening. (P. 50.)

The problem of colour photography solved at last. (P. 53.)

A. J. Newton chats on the rendering of colour into black and white. (P. 51.)

## EX CATHEDRA.

### Our Photographic Trade with Germany.

The official figures relating to German imports and exports of photographic apparatus and materials, which we published in our issue of June 21, can hardly be said to afford very satisfactory reading. A rough analysis shows that while in the first three months of the present year we imported about £156,000 worth of photographic apparatus and materials, we only exported goods to the paltry value of £6,700. Out of this small amount £4,800 represented apparatus, while our imports of German apparatus amounted to no less than £52,000. This figure apparently does not include lenses. Our largest imports were sensitive paper (£57,000), while it appears that Germany imported none of our manufactures. They, however, took £1,760 worth of dry plates from us while we imported none from them, which is a small mercy to be thankful for. Returns such as these are notably untrustworthy, for no one possesses the information needful to ensure accuracy. Some of the figures appear to us to be very doubtful, but the indication they give that things are by no means as satisfactory for us as they might be is no doubt accurate. The amounts given above are averaged from the tables as published; they are not exact, but not likely to be far out.

### Sky Values.

In these days of "oil printing," when values can be corrected or falsified at the will of the operator, the question of sky values is of some considerable importance. We are all agreed that white skies cannot be tolerated, but there are marked differences in the methods of representing an ordinary blue sky, and it certainly appears to us that some modern photographers are inclined to err in the direction of making their skies too dark. If the feeble blue of an English sky is represented by a grey tint of the proper value the effect is not usually displeasing, but a Mediterranean sky is many shades deeper in tone, and if represented in its true value in grey it is so dark as to be suggestive of a thunderstorm rather than a cloudless blue. With an Alpine sky the value is often even darker, for at great heights the sky tends towards blackness, as described by Sir William Abney. In such cases as these the correctness of true values is only appreciated by those who are familiar with the conditions. Others only see an effect of unnatural and unpleasant heaviness, and we think it very doubtful if these same "others" are not justified in their opinion. It is well recognised that in monochrome painting true colour values are not always desirable, even if possible, and these heavy grey skies in many cases certainly detract from the effect of intense light that is so characteristic of Southern scenes. It is true that the colour value of the sky is very low, but that fact is not at all appreciated by the observer

until he comes to reason it out, and attempts to record the sky in inadequate black and white. His principal sensation is of brilliancy—a deep, glorious blue in the sky and intense light everywhere; and this sensation of brilliancy is by no means realised by a photograph that shows a brightly lighted landscape under a nearly black sky. A correctly represented sky should give the sensation of space and luminosity, but these qualities are quite lost if the sky is too dark.

#### **The Alum Trough.**

Mr. C. E. Benham has recently drawn attention to the fact that the alum tank used for absorbing the heat from the illuminant in the optical lantern is no more effective for the purpose than a tank of simple distilled water. Indeed, we believe that it has been stated that the water is the more efficient of the two. In this case it is difficult to understand why the alum tank is so largely used. Possibly it is a case of mere superstition. Perhaps some "great" authority once recommended the alum tank, and everybody else believed him. Many things have been done, and are still done, for no better reason. But there is also a possibility that alum is preferred because the boiling point of the solution is a little higher than that of plain water. It is absurd to continue the use of alum if it is really no better than water, which is much more convenient; but perhaps some of our readers have personal knowledge of the comparative effects of alum and water tanks, and can speak with the authority of practical experience. The abolition of the alum solution would be a great convenience to many lanternists.

#### **The Workmen's Compensation Act, 1906.**

On Monday last the above Act came into force. We attempted, in our issue for February 22, page 135, to point out the main provisions of the same, but the more one reads this Act and the more imaginary cases are outlined the more drastic appear its provisions. It would be as well, therefore, if every one of our professional readers at once seized the opportunity to insure himself against any claim under this Act.

#### **Stereoscopic Projection.**

The old device suggested by D'Almeida and Du Hauron, amongst many others, of using coloured glasses before the positives has been again revived. The novelty, if there is any, appears to be in using one lantern only, and placing in front of the objective two prisms of 18 degrees angle, with their bases in contact. These naturally cause a commingling of the pictures on the screen. The fatal objection to this method is that every spectator must be provided with a pair of eyeglasses of the same colours as used for projecting the images. It is true that this presents no insuperable difficulty, and the cost would be comparatively small, for such lunettes with coloured gelatines instead of glasses, mounted on cards, can be obtained at about 5s. per hundred. The disadvantage of using gelatine is that it is very fragile and liable to be marked by damp fingers. Were it possible to use thin sheet celluloid suitably coloured, whilst the initial cost might be greater, the cost of replacement would be avoided to a great extent. Personally, we do not think that any method wherein any apparatus has to be supplied to the audience is commercial.

#### **The Deterioration of Paper.**

In 1898 the Society of Arts appointed a committee to deal with this question, and their report was by no means reassuring. At the annual general meeting of the Society held last week the Council, in its report, again calls attention to this matter, and says the Society has been reminded afresh that a large proportion of books are still being pro-

duced on perishable papers. This is due more particularly to the growing popularity of photographic reproduction and the necessity of adapting papers to the requirements of the "process" block, and the dominant demand for cheapness. The chief offender is the imitation art paper heavily loaded with clay, and calendered so as to produce a smooth surface at the expense of the substance of the paper. These, and other questions, are once more pressed on the notice of the Society, and with the object of again drawing public attention to the question, the Council have appointed the Committee. They hope that its report, when published, may contribute to a sounder public opinion on this very important question.

#### **Surfaced Papers.**

There is not the slightest doubt that the "process" block and the dominant demand for cheapness are the causes of the deterioration of quality of papers. But it may be said that many books in which blocks are used are not worth preservation, the more perishable the paper the better. We are aware that no amount of Committee reports will do away with the flood of cheap illustrated papers, which can hardly be called literature, and yet serve their purpose in saving away many an idle hour. Many books are now published on rougher surfaced papers, whilst the illustrations are inserted on art paper. The process block means of illustration has come to stay, and this must be recognised. A crusade against surfaced papers has occasionally raised by opticians, but without much effect. Certainly the rougher surfaces are more pleasant in the hand, but they are in most cases hopeless for half-tone work.

#### **Death of Dr. S. Czapski.**

It is with great regret that we announce the death of Dr. S. Czapski, which took place on Saturday last, June 29, after many months of ill-health. Dr. Czapski's work in practical and theoretical optics will be dealt with at greater length next week.

### **STRIPPING GELATINE NEGATIVES.**

THE removal of the gelatine film from its glass support is a task the difficulty of which is so exaggerated in the minds of many present-day photographers that many never think of attempting it in the not infrequent circumstances under which it becomes necessary. It was a different in the days of wet collodion, for if that fascinating process had one characteristic it was the aptitude of collodion film for leaving the glass, an aptitude which we have found to be actually a proclivity on the part of the film, and have thanked their stars if, during adverse conditions, they have brought the negative into a finished state without being afforded the spectacle of the film floating as a crumpled mass, down the sink. In those days stripping was the most common and certain of operations, yet it was actually no less so in the case of the gelatine plates, with an experience in both processes we would as soon strip a gelatine negative as one by the collodion process. It is well, therefore, that we descend to the practical methods which we advocate for the purpose.

Hydrofluoric acid, the agent which has been in use for the detachment of gelatine films for years past, is an essential constituent of the stripping mixture. A particular method of employing it is one which we believe originated with Mr. E. C. Middleton, of Birmingham, and was at one time disposed of to various firms, principally in the photo-engraving trades, as a secret process, and a monetary consideration. Indeed, unless we are mistaken, the identical preparation which we shall advise

upon the market as a proprietary article, and was treated with assiduity by the individual responsible manufacture; at any rate, the manipulation recommended for the use of the preparation was almost exactly to that of Mr. Middleton. Some modification of process was afterwards introduced by Mr. Haroldt, with the result that the method as it now stands is rapid and certain as can well be expected of any such process as the removal of a gelatine film from one glass plate and its transference to another.

The "black" solution, which we call the "plain" solution, is prepared as follows:—

Methylated spirit	...	...	...	25	ozs.
Water	...	...	...	1	oz.
Glycerine	...	...	...	1	oz.

The negative to be treated is first cut entirely through to within about a quarter of an inch from the edge with a pocket-knife, and is then placed level, which is easily done by supporting it upon three wooden strips.

An ounce of the stripping mixture given above is poured into a celluloid or ebonite cup, and a little hydrochloric acid added to it. About 10 to 30 minims of the special "white" acid is employed, but the above quantities cannot be exactly specified, as the strength of the mixture varies considerably. In a few minutes, not more than five, the portion of the gelatine between the edges of the glass will loosen, and on touching with a penknife can be removed. No better guide is to be had of the progress of the operation than the ease with which the strips, and therefore they should not be pulled off with any force, but the action of the mixture is to go on until each strip, without any pull whatever, comes gently and easily away from the glass. The film will then in all probability be in a condition to be removed. But a test must be made of the perfectness of the film. In the case of plates not larger than the size of a convenient method is to raise one corner of the film between the point of a penknife and a rubber band on the first finger until it coincides with the corner, this operation being repeated for each corner of the film. A neater way, however, and one which we prefer in all cases, is to pass a silk thread under the cane bow under the film, raising one corner of the film by contact with heated fingers. If the film is proved to be completely loose, the plate is drained and a little of the "plain" solution (i.e., without hydrochloric acid) poured over it. The glass plate for the reception of the film should be at hand, though the latter is removed directly to it depends on the operator's wishes as to the reversal or non-reversal of the negative. The film in either case is lifted from its support by a sheet of plain or of paraffined paper, the latter being preferred, and if it is laid down with that side in contact with the glass which was previously in contact the film will print just as before. If it is required, however, to reverse it, all that is necessary is to pick it up on a sheet of paraffined paper, and lay it down, not on a new glass plate, but on a second piece of paper, from which in turn it is transferred to the final glass support. This latter is a piece of glass bearing a thin coating of gum, so thin in fact that it is undiscernable to the eye, and is only disclosed by applying the moistened finger to the gummed surface. A number of these gummed plates may be prepared at a time, and will keep indefinitely, but it is a matter of only a few minutes to make one or two ready for use over an attenuated solution of gum arabic.

It is, however, to the precise manipulation. The

negative, having been drained of acid and had a little plain solution applied to it, this latter is in turn allowed to run off, and a further small quantity poured over the plate. A sheet of the paraffined paper is then lowered on to the negative and lightly squeegeed into contact. A touch of the penknife is used to cause the film to adhere to the paper, and the latter is then lifted off and lowered on to one of the prepared plates, on which also a little of the plain solution has been flowed. The paper is squeegeed down and drawn away again after a touch of the penknife to one corner of the film in order to prevent the film from coming away with the paper.

If, on the other hand, it is desired to reverse the negative as regards right and left in transferring it to its new support, the only additional time item in the process is the transference of the film from the first sheet of paper, not to the final support of glass, but to a second sheet of paper, from which in turn it is laid down on to the glass. Throughout these transferences the film, if properly treated, that is to say, if preserved from contact with warm and moist fingers, will not become distorted in the least, though it may suffer a very small amount of contraction, an amount, however, which is scarcely measurable.

The advantage of the paraffined sheets in comparison with the ordinary paper is that their semi-transparency allows the detached film to be laid down on its new support with the greatest certainty. Those who are trying the process for the first time are advised to employ a piece of glass an inch or two larger than the negative for the reception of the film, but the ease which is afforded by the paraffined sheets in the way of registration will soon enable even the tyro to use a glass of the same size as the negative which he is treating. The paraffined sheets are prepared by soaking thin not too highly sized paper in melted paraffin wax for a time long enough for the wax to be completely absorbed throughout all the pores of the paper. This may occupy half-an-hour, after which the sheets are removed from the molten wax slowly, so that as much as possible drains off. They are then kept flat in a book or between boards for use.

The process above described is much more expeditious than will be imagined by the reader from the necessarily detailed instruction which we have set forth. Under ordinary circumstances a negative may be taken in hand and be ready for printing on its new glass inside of twenty minutes. And several negatives may be treated in very little longer time. The large proportion of spirit in the stripping mixture is responsible for this expedition, and, as we have said, the only drawback to such a mixture is the slight contractile action which it exerts upon the gelatine film. The amount of contraction which actually takes place is not, we think, at all important; yet the property of the solution may be adversely felt in another way. It may happen, in the case of a negative which has hardened by long storage or by treatment with intensifier or other solutions, that the action of the spirituous solution may not be perfectly uniform over the whole surface. The action of the contractile solution being fairly rapid, any point which opposes that action may give rise to a buckling of the film around it, which distortion may be persistent and may be of such a nature that the negative is rendered useless. Such cases are rare in treating negatives, but that they may occur is always within the bounds of possibility in treating unknown negatives. For this reason it may be well if we draw attention to a supplement to the Middleton process which we owe to Mr. Holcroft, who published his results in "The Photogram" for July, 1903, and in our own columns for June 19, 1903, page 486.

Mr. Holcroft's addition consists in a mixture which, as regards expanding or contractile properties, is neutral.

This mixture, under certain normal conditions, was found to be:—

Methylated spirit	...	...	...	2 parts.
Water	...	...	...	1 part.

And the stripping mixture was prepared from it by the addition of 20 minims per ounce of hydrofluoric acid. It is possible that the proportion of spirit to water necessary to secure neutrality may vary with the temperature at which the mixture is used, but the variation is not likely to be great enough to make an appreciable difference in practice. Compared with the process already described the use of the neutral mixture has the advantage of perfect certainty and of complete freedom from contraction of the film, although for the majority of work the previous process is quite satisfactory enough in regard to these two

points. On the other hand, the neutral mixture, of greater content of water, is slower in its action, renders the film more tender and delicate to handle. Holcroft's conclusion as to the use which he would make the two processes is as follows:—"If pressed for time if I knew the previous history of the negative, and the glass was of good quality, I would use Mr. Middle's formula for stripping; if there was any doubt on that point, I should rely on the neutral stripping mixture. Our readers who may have need of such a process, regularly or occasionally, in their practice, may then be guided by the above distinction. In either case I commend the process to them, knowing that if the cautions which have been referred to are observed, no difficulty will be found in the practical execution of the method.

## THE WET COLLODION PROCESS IN PRACTICE

### II.

[The following is the second article of the series by Mr. E. W. Foxlee, which commenced in our issue of last week on the wet collodion process. The last article dealt with the preparation of the glass plate. The next article will deal with the silver bath and the various remedies for its often mysterious disorders.—Eds., "B.J."]

In the previous article the cleaning and polishing of the glass plates was fully described. The next subject for consideration is the collodion itself. It should be of good body, yet sufficiently limpid to flow easily and evenly over the plate without leaving streaks or ridges, and it is imperative that it must be free from structure when the negative is developed and dry. It must also be free from any opalescence when the film is dried. These qualities depend upon the quality of the pyroxyline and its solvents. Most operators on the Continent prefer to make their own collodions, and the photographic chemical manufacturers supply pyroxylines—"collodion wools"—of various characters for the purpose. In this country so many varieties are not obtainable, and the restrictions with regard to the conveyance of explosives renders it practically impossible to get them imported.

#### Making Pyroxyline.

The making of pyroxyline is not altogether pleasant work, as we have to be dealing with strong acids. However, these articles would not be complete unless the making of pyroxyline were included. The following is a formula that will yield a pyroxyline well suited for all round wet collodion work. It is taken from Hardwick's "Photographic Chemistry" (sixth edition), written when the author had ceased to be connected with the commercial manufacture of collodion, and I know of no better. It stands thus:—

Sulphuric acid, sp.gr. 1.845	18 fluid ozs.
Nitric acid, sp.gr. 1.457	6 fluid ozs.
Water	5½ fluid ozs.
Best carded cotton wool	300 grs.

The method is as follows:—Into a good size stoneware jar put the water, then the nitric acid, and afterwards the sulphuric acid, and thoroughly mix them with a glass spatula. The temperature will probably rise to about 170 deg. F., but the mixture should be allowed to cool down to 150 deg. F. It is then ready for the cotton wool. This should be thoroughly dried and pulled out in loose tufts of about 30 grs. each. These are immersed singly, and well pressed against the sides of the vessel, so as to saturate them thoroughly with the acids. The vessel should then be covered over and allowed to rest for seven or eight minutes. The cotton is then removed in a mass, into a shallow vessel, and as much as possible of the acid pressed out with the spatula. It is then quickly transferred to a large pan of cold water and well stirred about.

Then it is put into another pan of water and again well stirred. The quicker the larger proportion of the acids can be got off, the better it is for the pyroxyline. It must then be washed in several changes of water, until a piece of litmus paper pressed in contact with it shows no trace of acid. If any acid remains it will affect the collodion, causing it to become red, and very slow in working, after it is iodised. After washing, the pyroxyline is pulled out and put into a place free from dust to dry. In the forenoon just given the water stands at 5½ oz., but the writer prefers to use only 5 oz., for with the full quantity as given, everything is exactly right as regards the strength of the acids and the temperature, there is a tendency for some of the cotton to dissolve. With the full quantity of water water "sailing very close to the wind."

#### An Alternative Method.

Another formula for a photographic pyroxyline which gives excellent results and does not require quite so much stirring in the working, is as follows:—

Sulphuric acid	12 fluid ozs.
Well dried and powdered nitrate of potash	7 ozs.
Water	2 ozs.
Well dried cotton wool	2 drs.

Mix the water and acid together, then add the nitrate of potash and stir with a glass spatula until the nitre is dissolved and a transparent viscid liquid is obtained. Then let it cool down to 145 deg. F. If it goes below that, the vessel should be stood in another of hot water till it is raised to that temperature. Then the 2 drs. of cotton, in thirty-grain tufts, is introduced, and dealt with in the manner just described. Washing, etc., is the same. The latter is perhaps the better formula of the two when only a small quantity is required, but the former is much the preferable for larger quantities. In character the pyroxylines made with these formulæ are similar.

It has just been intimated that there are not the varieties of pyroxylines on the English market that there are on some of the other countries—Germany, to wit—but it may be mentioned that the high temperature pyroxyline of Messrs. Hopkins and Williams, Cross Street, Hatton Garden, is a very good one for collodion for the wet process. So is the "Celloidine" of Scherings, supplied by Messrs. A. and Zimmernann. This is pyroxyline that has been dissolved

vents evaporated from it. It is put up in packets, each of which, whatever be its weight, is taken to be one ounce of pyroxyline.

### The Solvents for Collodion.

In importance to the pyroxyline is the solvents—i.e. ether and alcohol—in which it is dissolved. If they are weak—i.e., contain too much water—the collodion, however the pyroxyline, will yield an opalescent film, or a “crappy” one. For the ether, that made from rectified alcohol will do quite as well as that from the methylated, but its specific gravity must not be more than .725. For the alcohol, the methylated cannot be used, even if it does not contain the mineral spirit, as it would quickly render the silver bath by reason of the impurities it would carry.

If methylated alcohol, in which the wood naphtha has been highly rectified, could be obtained, there is no reason why it should not be employed, and it would, of course, be much better than that which has to be used; but such a thing is not allowed by the Excise authorities, who insist on the use of the crude naphtha for the methylating. It is necessary, in order to avoid crappiness and opalescence in the collodion film, that the alcohol and the ether should be strong—the stronger the better. The strongest alcohol met with commercially is known as “commercial absolute,” which has a sp. gr. of .825. Equal parts of this and ether at .725, with a suitable quantity of pyroxyline, will yield a very structureless collodion. But the ether salts are but very sparingly soluble in absolute alcohol; therefore it is usual to make the collodion itself of certain proportions of ether and the strong .805 alcohol, and dissolve the iodides in a weaker spirit of .830—the spirit of wine of commerce—and then mix the two.

It has sometimes been recommended to strengthen weak collodion by shaking it up with well-dried carbonate of potash. It is true that this will strengthen the spirit by absorbing some of the water, but it will not bring its strength up to that of .825. At this strength the spirit still contains a considerable amount of water, which will hold some of the potash. Consequently the alkali would cause the collodion to take a short time to yield a rotten and powdery film, and, moreover, tend to render the silver bath alkaline and give bad negatives. If weak alcohol is strengthened by the potash, it must be redistilled, or it is useless for the collodion. But it is not necessary to strengthen weak spirit while it is of suitable strength is a regular article of commerce.

### Iodising Compounds.

In the above it is mentioned that the salts used for the collodion are but sparingly soluble in strong alcohol. Therefore it is usual to make up the collodion in the first instance with the full quantity of ether and half the quantity of alcohol, which should be the strongest—i.e., .805, or commercial “absolute,” and dissolve the iodides in a weaker one of .830. The two are then mixed for use.

In this stage it may be as well to consider the various iodides used for collodion, as they all have different characteristics. In the earliest days of the process the collodion was, very commonly, iodised with iodide of silver dissolved in a solution of potassium. Indeed, one of the leading manufacturers of those days named his collodion “Xyloiodide of silver,” and advertised it under that name. However, the use of iodide of silver was soon discontinued. For a long time iodides only were employed, and they are really the best when the pyrogallol developer is employed alone. It was only when iron, as a developer for negatives, became general that a bromide was used.

The iodides that were used were those of ammonium, potassium, and cadmium. Each of these has different characteristics. The first-named is fairly soluble in spirit, but when iodised with it soon changes in colour, and in a few

days becomes very slow in action. Iodide of potassium is more sparingly soluble in spirit, but the collodion iodised with it will keep longer than that iodised with ammonium; but after a week or two it also becomes dark and, like the other, very slow. In dull weather, or when very rapid exposures were necessary, it was customary to iodise only a small quantity and use it directly afterwards. Iodide of cadmium is far more soluble in spirit, and collodion iodised with it has much better keeping qualities than that iodised with either of the two first-named salts, but cadmium iodide has a tendency to interfere with the limpidity of the collodion, and make it more difficult to obtain a perfectly even film on the plate. Now, however, none of these salts are employed by themselves, but mixtures of them—usually ammonium and cadmium—with a certain proportion of a bromide, which greatly enhances the sensitiveness of the collodion for an iron developer, and, as a matter of fact, all modern collodions contain a bromide of one kind or other.

### The Plain Collodion.

The following is a good formula for general all-round work. It is given for a pint of the finished collodion, but it is better to make a larger quantity than this at a time, as it keeps good for a long while, if kept in well-stoppered bottles, or, preferably, in corked bottles, if the corks are of the best quality. The advantage of making up a good quantity at a time is that any undissolved particles of the pyroxyline have time to subside, and the clear portion can then be decanted as required for iodising:—

Pyroxyline .....	from 100 to 140 grs.
Sulphuric ether, sp.gr. .720 .....	10 ozs.
Alcohol, .805 (commercial absolute) .....	5 ozs.

Into a pint bottle put the alcohol, and then the pyroxyline, and well shake until the cotton is thoroughly saturated. Then add the ether. If the pyroxyline be added to the mixed ether and alcohol a glutinous mass will be formed, which is more difficult to get into solution. It will be noted that the proportion of pyroxyline is not very definitely given, for the reason that different samples vary as to the viscosity of the collodion they will give. Some give, with the same proportion of solvents, a thicker collodion than do others.

### The Bromo-Iodising Solution for Iron Development.

The proportions here given are for a pint of collodion; but, as with the plain collodion, it is best to prepare a larger quantity at a time, as, like the plain collodion, it keeps well.

Iodide of ammonium .....	45 grs.
Iodide of cadmium .....	45 grs.
Bromide of ammonium .....	20 grs.
Alcohol, .830 (S.V.R. of commerce) .....	5 ozs.

The best way of compounding the solutions is to put the salts in a clean and dry mortar, grind them together in the dry state, add the spirit an ounce or two at a time, and then pour off into a bottle as they are dissolved, finally rinsing out the mortar with the remaining spirit. One part of this iodiser is to be added to three parts of the plain collodion. After the addition, the bottle should be vigorously shaken for a minute or two. The collodion is best iodised some days, or a week or two, before it is required. It then works cleaner, and yields more vigorous negatives, than if it were employed directly after iodising. With this iodiser the collodion will remain in good working order for some months, if kept in well-stoppered bottles. Another formula, which is an excellent one for general work, is:—

Iodide of ammonium .....	40 grs.
Iodide of cadmium .....	40 grs.
Bromide of cadmium .....	20 grs.
Alcohol, sp.gr. .830, S.V.R. ....	5 ozs.

Collodion iodised according to this formula should be kept for a month before use, and will retain its sensitiveness for six months or more after iodising. It should be mentioned here

that the older the collodion, after iodising—within certain limits—the cleaner it works and the denser will be the image with the first development. On unduly long keeping the collodion yields films that are rotten, or pliable, and which are liable to break up in washing the negatives. They are also apt to become dissolved when the negatives are varnished, should the varnish be made with strong spirit. There are numerous other formulæ for iodising solutions, but the above may be taken as typical of the best of them.

#### Ready-made Collodion.

Although formulæ are given for making collodion—and these articles would not be complete without them—most workers in this country prefer to purchase it ready made, and the practice is one I strongly recommend to the beginner. There are not so many brands of collodion on the market now as there were when that process was the only one in vogue. But some of the oldest and most renowned manufacturers still make a feature of it—such as Mawson and Swan, R. W. Thomas

and Co., and the Autotype Company. They supply collodion specially made for different purposes—portrait negatives, positives, copying, photo-mechanical process, etc. The two named firms supply the collodion and iodiser in separate bottles; the last-named only send it out ready iodised, but that state it retains its good qualities for several months.

After many plates have been coated from the same bottle the collodion becomes thicker, and requires to be thinned. The ether is more volatile than the alcohol, it flies off in larger proportion than the spirit. Therefore, the thinning mixture should contain a larger proportion of the former than the latter; in the collodion as made there are equal parts of ether and alcohol, but these get altered as the collodion is used. The following are suitable proportions for the thinning mixture:—

Sulphuric ether, .720 .....	3 parts
Alcohol, .805 .....	2 parts
E. W. FOX	

## TANK DEVELOPMENT FOR PROFESSIONAL PORTRAITS.

[A record of experience which should interest the commercial photographer is contained in the following article from our New York contemporary, "Wilson's Photographic Magazine," which we publish with the comment that next week we shall give a contribution from one of our British practical workers, Mr. G. T. Harris, giving his own opinion of a similar process in landscape work.—Eds. "B. J. P."]

TANK development has come to stay. It may be a little long in reaching its full estate among both professionals and amateurs alike, but that it will eventually supersede all other methods of development in 99 per cent. of exposures is as sure and certain as was the march of the dry plate to almost universal use.

There must be a reason—several of them. As far as the professional maker of portraits is concerned the reasons are as follows:—

Tank development gives better negatives.

Tank development gives more of them (practically no failures).

Tank development saves time (which is money).

Tank development saves chemicals (which cost money).

Tank development saves labour (which costs money).

Tank development gets all there is in an exposure, out of it.

Can the tentative developer always be sure of that fact in his way of working?

Tank development puts it "up to" the operator with no possibility of his blaming the developer.

Tank development saves temper and promotes health, as it entirely does away with the necessity for long sittings in stuffy dark-rooms—bad in winter but a veritable Sheol in summer.

There is the case for this system of work. Now for the explanation and the proof.

Tank development is a very simple process. It consists in putting a number of plates together into a tank, in which vessel they are held in an upright position, and surrounding them with a weak solution of normal developer which is allowed to act for a certain interval at a certain temperature. The interval over, the plates are removed and fixed in the usual manner. That so simple a process can by any possibility be better than the old way of juggle, dabble, slop, and change from one tray to another, the skilled dark-room man will be loath to admit, but I am not making assertions only—I am stating facts proved and settled by the leading photographic chemists, the leading manufacturers of photographic goods, and the leading and most famous photographers the world over. The mere fact that the largest manufacturer of photographic goods in the world advises tank development should be convincing to anyone who will think, even if he cannot believe the chemists and the experimenters, for why should a manufacturer advise this process, if it would not give his customers better results? Presumably he is looking for money and success and satisfied patrons, like the rest of the fraternity.

#### The Weak Developer.

Any dark-room man of the old school will agree that a weak developer is the best in which to start an under-exposed negative.

He will agree that a weak developer cannot hurt an over-exposed negative. In tank development you have the weak solution. So the dark-room man will be satisfied. But he cannot, usually, see that an under-exposed and an over-exposed and a properly exposed plate should be left in the developer the same length of time. That is because he confuses the effects of exposure with development.

Exposure unalterably fixes the range of the tonal scale. In tank development exposure has been too short, the shadow detail is absent and the tonal scale is short and steep. If the exposure has been too long the shadow detail gets undue prominence, and the tonal scale is long and low. If the exposure has been right, the tonal scale is right. Development fixes the scale of the tonal scale—the distances, as it might be put. Exposure determines the proportions between high-light and shade, development the distance between the tones, in other words. To make this plainer, let us refer to the old simile, that of comparing development to a flight of steps. There are three steps. The lowest is shadow—the second half-tone—the third high-light. Each step is six inches higher than the one below it. This distance is determined by exposure. Now, if a carpenter comes along and makes the distance between each step twelve inches—there their relative proportions are the same—but the distance between each is greater. The carpenter is the developer. He has built on each step a different amount. He raised the second step six inches, to make it twelve, and he raised the third step twelve inches, to make it twelve above the second, and the first step he did not touch. That is prolonged development, which increases the contrast between tones in proportion to their exposure.

This being so—and the actual proof is watching a plate in the tank and seeing the lights come up first, the half-tones next, and the shadow last—it follows that all development does is to regulate the distance between the tones—the contrast of the negative. Incidentally, and only incidentally, the time of development regulates the density of the negative, which is an entirely different thing from its relative opacity.

#### Tank Development and Wrong Exposures

Now let us see how this works out in the tank. We will use three plates. The normal exposure on some subject—any subject—let us say, is five seconds. We give one plate one second, one plate two seconds, and one twenty-five seconds. We put them all in the tank with a certain developer at a certain temperature, and leave them a certain time, let us say half an hour. If we examine the plates at the end of ten minutes, we will see but little high-light detail might have been expected. The second, or correctly exposed plate is one-third through—all the detail is out, but it is thin. The first or over-exposed negative is already black. Now suppose we

these negatives, would any one be good? The first would be a light in an expanse of glass. The second, a normal negative, and developed, would be too thin to print. The third, over-exposed, would fix out, of course, with no contrast. None of them had enough carpentry!

At the end of the time when the normal negative is properly developed—at the half hour—if we fix all the plates, what do we get? Under-exposed plate has a good deal of contrast but some detail in shadows; the normal negative is normally developed, and over-exposed negative is very thick, but it has contrast. Printed in present condition or reduced it will give a passable print. Of the three negatives, you must admit, will give a better than the same ones would if taken out of the solution under-developed. But let us follow a third set through over-development, see if we can improve any of the negatives. Can you improve normal exposure by over-development? Of course not. Can you have an under-exposure by over-development? More emphatically, no. All over-development does for under-exposure is to the high-lights and give a soot and whitewash picture.

#### Over-Development for Over-Exposure.

When you improve an over-exposed negative by over-development? Why you never thought about it. Try it. We leave the plate an hour instead of half an hour. Compared with the half hour, normal development of the over-exposure, the prolonged development shows greater density and less contrast. It has begun to develop down the scale again—in other words, the high-lights have stopped developing (because they are completely out), the shadows, over exposed, have begun to build up to the high-lights, decreasing the contrast as the density increases. And at the end the negative is too thick to print from.

Can you, if you cannot improve a negative of either under or over exposure by under-development or by over-development, why is the case proved for a normal development for all kinds of cases?

#### Studio Requirements.

There is another side to this question which the amateur seldom sees. In the studio there are two classes of exposure—that of great contrast, when the head is against a dark ground, and less contrast, when a white drapery, for instance, is against a white ground. It is customary to develop these classes differently. Now, it has been suggested by any sensible person that all negatives of all classes can be developed in the formula of one man. Each man must adjust his own formula and time to what he wants in the studio—that once found, he can put all his negatives into his hands with the full assurance that he will get what he wants. If, on the other hand, you find that the tank development for both white and dark grounds gives you more or less contrast than you want, you must either alter the time of the developer or alter the exposure. It is a simple matter to adjust things so that the same developer for the same time will give you what you want in results from varying exposures. By results I mean prints. But as the time is so variable to make a print figures largely in your expense account, it is well that you had best compromise with two tanks, one for each class of negatives and one for another class, in order that relative density of the two sets will be similar, saving time and space in the printing room. This suggested compromise is made offering before the god of commercialism, and in no way contests the facts that the results—the prints—could be obtained from the negatives made in one tank, if you had the time to use thick negatives in the printing room.

#### A Pyro Formula and Rules for Practice.

Give the system a trial and you will discover its many advantages.

First, get a good tank. Do not use an old fixing box. A tank for 7 negatives can be obtained for two dollars.

Second, for a few days, make a sufficient number of duplicate exposures in the studio to allow the tank to be tested without hurting business if you make mistakes.

Third, make up this formula, fresh, and from dry chemicals, just as you want to use it, and not before:—

Sodium sulphite .....	90 grains.
Sodium carbonate .....	60 grains.
Pyro .....	30 grains.
Water .....	48 ounces.

This will probably take about 96 ounces (double the above) for one

5 by 7 tank—you can ascertain the exact measurement of your own particular tank and alter the amount proportionately.

Fourth, see that this solution is not more than 65 deg. F. in temperature, and if the room is at all warm make it 60 deg.

Now, in the dark-room, put the plates in the racks, with films facing in toward the centre. Insert the rack in the tank, which should be full of the solution, move up and down in the solution a few times, to break bubbles, put on the cover, turn up the light and take the time. Let it alone for twenty minutes. Pour off developer and fix. I imagine you will have a surprise.

But as I do not know what plates you use, how you like your negatives, or the conditions under which they were made, I do not pretend to say that this particular tankful will suit you as well as your own formula. I would suggest, after you have done this, that you take your own formula, as usual, and develop a plate, as usual, taking the time. Then dilute it enough to fill the tank, multiplying the time of development by the amount of dilution. But do not expect too small a quantity of solution to do too much work. Strange though it may seem, 60 grains of pyro will develop a dozen 5 by 7 plates, but do not use less. In other words, do not dilute your own solution more than to the proportions of pyro per ounce given—1 grain to 1½ ounces of water.

Adjust your tank development in this way—increasing the time—or decreasing it, as you want more or less contrast. Do not alter formulas until you have done all you can by altering time. Once adjusted so you get what you like—stick to it, until you are thoroughly familiar with the process—then try experiments if you wish.

#### Points in Economy.

Now as to the saving of chemicals—with 1 ounce of pyro, 2 of carbonate of soda, and 3 of sulphite, you can develop ninety-six 5 by 7 plates. Compare that with your usual chemical output. It takes you half an hour to the dozen in the tank—and you can work as many tanks as you want at the same time. Your total time in the dark-room is the time it takes you to load the tank and put on the cover.

That it gives better negatives in the long run you can prove for yourself, as I and hundreds of others have proved. That it gives more of them, since you have no failures not due to exposure, is obvious. That it saves time is self-evident. You could, with eight tanks, develop ninety-six plates in an hour. Try to do that with a tray! That it saves chemicals I have shown above. That it saves labour is also easily seen—if one man can develop a hundred plates in one hour, where it formerly took him half the night, it is obvious his spare time can be spent in doing something else. That it gets all out of a negative the exposure puts in, is certain—see the opening argument about over and under developing any sort of an exposure. It puts the success or failures up to the operators, because, if all plates are developed the same way in the same solution at the same time and at the same temperature, and he gets a good result to-day and a poor to-morrow, obviously the fault is elsewhere than in the dark-room. It removes, in other words, one set of personal equations from a profession that is too full of them.

The American idea is always for the "square deal." Do not, as I said before, use a grooved fixing box and call it a tank—you will get into trouble one way or another sure. Do not use your own formula first—use mine first and then yours. If yours is not as good as mine in the results it gives, you will then know it is the formula. If you use yours first and get poor results, you will not know it—you will blame the tank. This is no diatribe against your formula—it may be the best in the world but unsuited for tank work.

Do not look at the plates while they are developing. One of the beauties of this process is the absolutely clean, clear negatives it gives, and looking at plates in a red light is not conducive to this absolute lack of fog.

Now, just to put you in a good humour as we close, I want to confess that I am a convert to this system within the last two or three years. A professional portrait-taker who stands very high came recently to me with a long face, a tale of a sick dark-room man, and a box of plates. "Would I help him out and develop these? He was sure they would be done to perfection." They were. I did them in a tank. Later he raved over my supposed skill to his partner, and wished he knew how they were done.

C. H. CLAUDY.

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for patents were made between June 17 and June 22:—

**PLATES.**—No. 13,957. Means for the daylight loading and unloading of photographic sensitised plates. Rupert Richard Allen, 18, Southampton Buildings, London.

**CINEMATOGRAPHS.**—No. 14,058. Improvements in cinematograph projectors, cameras, and like machines. Ernest Francis Moy and Percy Henry Bastie, Greenland Place, Camden Town, London.

**PLATES.**—No. 14,110. Improvements in and relating to means for developing photographic plates, films, and the like. Percy Albert Craven, 11, Maiden Lane, London.

**APPARATUS.**—No. 14,122. Improvements in photographic apparatus. David L. Morris, 209, High Street, Swansea.

**CINEMATOGRAPHS.**—No. 14,422. Improvements in or relating to cinematographs and the like. Arnold Thackhall-Browett, 18, Hertford Street, Coventry.

**PETITION FOR EXTENSION OF PATENT.**—In the matter of letters patent granted to William Friese-Green, of 203A, Western Road, Brighton, in the county of Sussex, photographer, and bearing the date of November 29, 1893, and No. 22,954. Notice is hereby given, that it is the intention of the said William Friese-Green, as inventor and patentee of the above patent, to present a petition to His Majesty's Lords of the Privy Council, praying that the term of the said Letters Patent may be extended. Notice is hereby given, that on the 17th day of July, 1907, or on such subsequent date as His Majesty's Judicial Committee may fix for hearing the matter of the said petitioner, any person or persons desirous of being heard in opposing the said petition must enter a caveat to that effect in the Privy Council Office on or before the 17th day of July next. Dated this 7th day of June, 1907. William Friese-Green, 203A, Western Road, Brighton.

### COMPLETE SPECIFICATIONS ACCEPTED.

*These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.*

**STEREOSCOPIC ATTACHMENT FOR CAMERAS.**—No. 5,267, 1906.—This invention relates to the improvements in the method of and apparatus for taking stereoscopic photographs, and more especially to that type of apparatus in which an arrangement of mirrors is set in front of the objective of a camera in such a manner that two views are projected on the screen at the correct distance apart for stereoscopic effect.

Now this invention provides, in combination with the mirrors in front of the lens, rests, stops, scales, or the like, whereby the mirrors can without trial be held or adjusted in correct position for production of the double stereoscopic picture in a camera of given type.

When a plane mirror is placed in front of the objective of a photographic camera in the direction of its optical axis there will appear on the ground glass of the camera a picture of the reflected view visible in the mirror from the centre of the camera objective, the size of this picture depending on the dimensions of the apparatus and on the size, position, and distance of the mirror. It is in practice generally sufficient to consider only the special case in which the plane of the mirror is vertical, the axis of the camera being horizontal, each incident and reflected ray lying in this case in the same horizontal plane; the simplest case being that in which the mirror is inclined at 45 deg. to the optical axis, so that every horizontal ray incident on the mirror in a direction at right angles to this axis is reflected in a direction parallel to the axis. In this case a horizontal ray incident on the mirror at its point of intersection with the optical axis will be reflected along its axis, passing through the centre of the objective and producing an image point at the centre of the ground glass. If now the inclination of the vertical mirror to the optical axis be varied, this image point will be correspondingly deflected horizontally to the right or left of its former central

position on the ground glass. Now the determination of constant elements already referred to is mainly based on a well-known optical principle also involved in the construction of the quadrant and sextant, that when a ray or a sheaf of rays is incident on a plane mirror, and this mirror is inclined through a certain angle about an axis at right angles to the plane of an incident and its reflected ray, the reflected sheaf of parallel rays is thereby caused to rotate through an angle double that through which the mirror has been revolved.

The principles stated in the above paragraph are mathematically proved, and various figures given showing the necessary arrangements of mirrors and lens. Bug-Gesellschaft, m. n. 4, Am Zirkus, Berlin, Germany, and Gustav Barnack, Brauerstrasse, Gross-Lichterfelde, Germany.

**DAYLIGHT LOADING DEVICE.**—No. 13,038, 1906. The present invention relates to improvements in devices for loading photographic cameras with plates, films, or the like in daylight, and particularly to those devices in which the plates or carriers are not transferred to a storage compartment after exposure, the object being to prevent the entry of light to the plate or film in its receptacle after the exposure has been made, due to the slide being imperfectly light-proof when replaced. According to this invention, it is proposed to provide a light-proof carrier for the sensitised plate or the like, with a back

Fig. 2.

Fig. 3.

support for the plate, such backing being provided at the top and on both sides with pieces adapted to be folded round the film in order to hold same, and at its lower part with a double fold or flap having flexible lips or bends so that a light-tight joint is formed by the lower edges of the slide intruded between

Fig. 4.

Fig. 5.

the bends or lips of the flaps and the backing. The lower edges of the slide are formed with transverse ribs adapted, on withdrawal of the slide for exposure, to engage the flexible lips of the flaps and draw them into a position almost at right angles to the back of the slide thereby holding the flaps open to again admit the ribs or bends of the slide after exposure. The backing is provided, at the end at which the flaps are located, with inclined lateral projections adapted to co-operate with the correspondingly shaped grooves or recesses in the exposure frame for the purpose of guiding the carrier correctly to, and then retaining it in, its

Fig. 1 is an elevation of a carrier embodying the features of the invention. Fig. 2 is a longitudinal section of the lower part thereof, on a larger scale with the film or plate in place. Fig. 3 is a similar section, showing the parts in a different position. Fig. 4 shows the exposure frame with the carrier in place and Fig. 5 is a longitudinal section of same. *a* is the backing on which the film, plate, or the like *b* is placed and is retained in place by folded-down narrow strips or lugs *c* at the upper end and the sides of the backing which form a part of same. At the lower part of the backing are arranged two flaps or leaves, *d*, *d*, one on each side of the backing, which extend laterally beyond the edges of same to form the projections *e*. The open edges of the flaps *d* are provided with turned-in lips or flanges *f*, *f*, adapted to lie in contact with the slide *g* on both sides thereof, and close the same in a light-proof manner while the slide is in place; but on the withdrawal of the slide the lips *f* will assume a position approximately at right angles to the backing *a*, and will thereby hold the flaps open in readiness for the re-introduction of the slide. Fig. 2 shows the flap *d* closed, and Fig. 3 shows them open. *g*<sup>1</sup>, *g*<sup>2</sup>, are transverse ribs on the lower edge of the slide which abut against the lips *f* on entering or leaving the flaps and cause the latter to close or open. The slide *g* is formed as a casing of paper or other light material adapted to entirely surround and enclose the backing *a* when in the position shown in Fig. 1.

Figs. 4 and 5 show how the carrier is secured in place in the exposure frame, which latter consists of two parts or leaves, *h* and *i*, having opening, *k* and *l*, respectively. This exposure frame has the important advantage that it allows the picture to be focussed through two apertures by the insertion of a ground glass plate, it being of course understood that the apertures *k* and *l* correspond in size with the picture. Such a frame, serving the double purpose of exposure and focussing device, may be termed an adapter. Emil Wünsche Aktiengesellschaft für Photographische Industrie, of Reick, near Dresden, Germany.

## New Trade Dames.

BERLIN.—292,747. Pictorial Postcards. The firm trading as the Bradford Pictorial Postcard Co., 72, Thornton Road, Bradford, Yorks; manufacturers. May 6, 1907.

ROGRAPH.—No. 292,947. A bromide of silver photographic pigment paper. The Rotary Photographic Co., Ltd., registered office, 12, New Union Street, Moorfields, London, E.C.; manufacturers. May 13, 1907.

ONA.—No. 292,948. A Self-toning Photographic Printing-out Paper. The Rotary Photographic Co., Ltd., registered office, 12, New Union Street, Moorfields, London, E.C.; manufacturers. May 13, 1907.

NOTHER ADDLED EGG.—The "Magpie" is again in trouble. In week's issue of the "Amateur Photographer" he says: "The meeting of the R.P.S. before the long vacation has been held; 'Blenheim' is also 'estivating,' and a good many of the notable names in the photographic world are absent holiday-making. The cats are away the mice take good care to play, as I am reminded by the fact that the genial editor of the 'B.J.P.' being on Continent, his *locum tenens* has taken the opportunity of airing exquisite courtesy and still more irreproachable spelling. It has well said that the blame of some individuals is more creditable is the praise of the rest of mankind. I certainly think that a keen technician as is the individual referred to cannot find anything more serious to complain of than an absurdly trifling variation in the spelling of a man's name, there must be far more the average of absolute accuracy in my chatter than is met in the rest of the photographic Press, not excluding my amiable friend's own writings, many of which I have before now found to be with errors." What a pity it is that this sore and bedraggled does not make a little more sure of his facts. His statement of the *locum tenens* taking any opportunity to do anything in the way of the crime referred to in particular is, in parliamentary terminology, a terminological inexactitude. The clumsy attempt to put up his painful ignorance of the whole subject of the "Perkins phenomenon" by calling it "an absurdly trifling variation in the spelling of a man's name" is worthy of the high reputation of this poor

## Analecta.

Extracts from our English weekly and monthly contemporaries.

### Portraiture at Home.

The expression in portraiture (writes Mr. E. T. Holding in "The Photographic News") is a very important thing, and it is necessary that it should not be unusual or exceptional; for instance, one does not want a sitter in a portrait studio to be gazing heavenward. The unæsthetic lines of a man's dress do not always lend themselves agreeably to the prominence afforded by a light background, and one is fortunate indeed if one can secure a garment, built on broad and flowing lines, and masking a somewhat unpicturesque jacket. One should always exercise a censorship upon the clothes of one's friends before attempting to perpetuate them by photography, and, where necessary, substitute a garment that will lend itself to pictorial treatment for the one of everyday wear. Where the sitter does not lend himself to the graceful and idealistic sort of arrangement I have aimed at here, something frankly characteristic may be attempted. One portrait negative I recently made revealed what I had for a moment regarded as the unfortunate fact that I had omitted the top of my sister's cranium. This was, however, after a visit to a recent exhibition of portraiture, discovered to be quite as it should be, and was in reality a demonstration of that fact, discovered in America, that a part is greater than the whole. I thus found myself, as it were, on the very crest of the wave of modern photographic portraiture. Encouraged by this inadvertent triumph, I carried the principle further, omitting still more of the top, and all of the back of his head. Whether this reaches finality I hardly know, but much can be done with a trimming knife.

### The Dixio Method of Stereoscopy.

In a description of the new method of Dixio stereoscopy, in "The Photographic Monthly," the chief advantages are stated to be: (1) That any sized picture (even to several feet in diameter) may be easily seen in stereoscopic relief; (2) that it is equally applicable for prints or transparencies (positive or negative), which is an immense advantage for medical and surgical radiographers, and others who wish to "read" large negatives; (3) (arising out of 1), that the necessity for fine smooth surface and strong illumination is removed, as there is no need for a lens to magnify the picture, which makes rough texture offensive in the old stereoscopes; (4) that there is no eye strain. Many people who cannot see relief at all in the old-fashioned stereoscopes see it at once by Professor Pigcon's method. The new system, briefly, consists of using two pictures of the same subject, made from separated view-points, and one of them reversed as regards right and left. To view them a special stereoscope, somewhat like the two backs and one stiff leaf of an album, is used. Near the outer edge of the leaf is a small piece of optically worked mirror glass, and when the views are in place one eye looks directly at one print while the other sees the second print reflected in the mirror. If the prints are properly placed (the Dixio stereoscope provides for this), the image is instantly and brilliantly seen; and the first view of a 7 x 5, or large stereoscopic subject, is usually a revelation and a delight even to those who are familiar with ordinary stereoscopy.

### Ozobrome from P.O.P. Prints.

Ozobrome (writes Mr. Ernest Elder in "Photography") may be obtained, both by the "transfer" and "non-transfer" methods from P.O.P. prints—(1) unfixed, (2) fixed, (3) unfixed (gelatine), self-toning P.O.P. In the first case, that of the unfixed print, the P.O.P. print after removal from the printing frame is thoroughly washed to remove the free silver, and then, after being hardened by immersion for five minutes in 10 per cent. formaline, is washed for fifteen minutes. There is not much advantage to be gained by using unfixed prints for the transfer method, because in such a case it is not possible to re-develop the bleached image to its original state. But it is preferable to use unfixed prints for the non-transfer method, and to clear away the partly bleached image with Farmer's reducer. Prints to be fixed should be printed deeply, fixed in a hardening and fixing bath, composed of: Water, 20 ounces; hypo, 3 ounces; potassium metabisulphite,  $\frac{1}{2}$  ounce; chrome alum,  $\frac{1}{2}$  ounce; and then thoroughly washed to remove all the hypo. These fixed prints are equally suitable for either the transfer or non-transfer method. If used for the latter method, the partly bleached image may be removed by Farmer's reducer, or it may be re-developed and toned. Rodinal and metol-hydroquinone are very suitable developers for the purpose. After fifteen minutes' washing the print may be toned in a bath composed

of 20 per cent. solution of sodium sulphide 3 drops, water 1 ounce. In the case of weak oxobromes, this toning of the underlying image greatly adds to the richness of the finished print.

### Shadows.

The sun, in his capacity of shadow-thrower (writes Mr. Will. A. Cadby in "The Amateur Photographer"), can be of service to the photographer. Often a view that has for some particular reason to be taken will be lifeless and dull without shadows, or a part of it may appear too blank a space, and require breaking up. In such cases, if we look out to choose the right hour of the day, shadows may be made to supply a real want, and will improve considerably, and sometimes even add decorative value to, our print. Obviously, early morning and late evening are the times when shadows are most likely to be useful, for then they are long and usually more graceful and inclined to idealise the subject that throws them. But shadows can take an even more prominent and important position still. They may be made the chief subject in, and the whole reason of our picture, if we are content to devote ourselves to delicate bits of drawing. I remember once in the mountains seeing a sketch-like form depicted in shadow against a big, slanting rock. On looking for the original I found it was the most ordinary bit of underwood, but the rock sloped away from the branch, distorting it somewhat, and giving it almost the look of a Japanese drawing, suggesting quite a conventional and decorative study, that the poor little model, blowing in the wind, and defying my camera, was, when looked at in real life, quite incapable of impersonating. The forms of shadows cast by trees are most varied. They range from the fine tracery of thin branches to the bold outlines of the great trunks. Besides which, there are all sorts of other objects that cast shadows which will well repay attention. The possibilities of shadow work are almost unlimited. One shadow will go on altering its shape right through the day, and if we have the time and patience we can wait until it appears just as we wish.

### Hand Camera Work.

As many of the lenses on the cheaper cameras (writes Mr. G. A. Fowkes, in "Focus") do not work at very large apertures, it will be necessary to use fairly rapid plates, and isochromatic plates will frequently be of service, and never be a disadvantage. It is always safer to have them backed, as one never knows exactly what class of subjects may be met with, and when working against the light, or when there are bright clouds about, the improvement effected by their use is very marked. On open subjects, in bright light, with short exposures, it is sometimes possible to use a pale isochromatic screen to advantage, whilst when photographing on glaciers in Switzerland, or sea and sky subjects in summer, it is almost impossible to under-expose, and a fairly deep screen may be used with safety. When a reflex camera is not used, and it is not possible to focus the subject on a screen, particular attention should be paid to the lighting of the scene, as it is not easy to judge the effect when a small brilliant finder is used. When the light comes directly from behind a very flat picture will be the result. It is better to have a side lighting, whilst a front lighting is very effective with some subjects, and especially when the sun is setting. In the latter case it will be necessary to shade the lens from the direct rays of the sun, and this can be done by holding a piece of cardboard slightly above the camera, care being taken that it does not cut off any of the picture. A proper sky shade is a very useful adjunct to the outfit, and one can easily be constructed out of a cardboard tube, which will just slide on to the lens hood. The tube need not be more than about two inches in length, and it should be blackened with a non-shiny satin.

THE HALIFAX PHOTOGRAPHIC COMPANY ask us to announce that their printing and enlarging department is open to receive orders from amateurs as well as professionals, as it is not restricted to trade work. If any of our readers have not yet applied for a copy of the firm's "Art Cyclopædia," they would do well to do so without delay, as the issue is now nearly exhausted.

THE HACKNEY PHOTOGRAPHIC SOCIETY, which for so many years has held its meetings at the Pembury Hotel, has now changed its headquarters, and will in future meet in the board-room, Hackney Baths, N.E. The official opening is fixed for July 9, at 8 p.m., when the members will be glad to see any gentleman living in the district.

## Dew Apparatus, &c.

A Cutting Shape Holder. Sold by Sichel and Co., 52, Bun Row, E.C.

This little device consists of a desk with metal top and a spring block, under which the paper and cutting shape may be placed firmly gripped, for the cutting down of the prints. It is an ingenious and practical device, which will be found of considerable benefit in the printing-room, as it entirely obviates any slipping of the paper or cutting shape. Price 6s.

The Brownie Daylight Developing Box. Made by Kodak, Limited, 34, Clerkenwell Road, E.C.

The users of Brownie cameras will welcome this simple little device, as it will enable them to develop their films in daylight. It is simply a light-tight metal box provided with a pair of rollers actuated by an external crank, by which, while one end of the film is held at one end of the box the rest is unwound, passed round a roller at the other end of the box, and so back to the starting point. The film thus makes a single loop in the box, the sensitive surface making no contact with any part of the mechanism, so that the developer, which is poured in before the film is unwound, reaches every part of the film without hindrance.

The box is provided with a rocking standard, and the operator has simply to rock it on this for six minutes. The developer is then poured off, and the film is rinsed and removed to the fixing bath, the whole of the operations being carried out in daylight.

The box takes the ordinary Brownie tank developing powder, which, dissolved in the necessary quantity of water, gives a developer which fully develops the film in the stated time of six minutes. The price of this is 5s.

A New Folding Pocket Kodak. Made by Kodak, Limited, 34, Clerkenwell Road, E.C.

This camera is designed for 5 x 4 pictures. It is fitted with rapid rectilinear with iris diaphragm, and the F.P.K. automatic shutter, giving time, bulb, and instantaneous exposures with trigger or pneumatic release. It has also rising, falling, and cross frame

brilliant reversible finder, and the automatic focussing device which upon an indicator being set for a given distance, checks the focus as soon as it reaches the proper extension. The new Kodak takes the daylight loading spool used with the No. 4 Screen Focus Kodak. The workmanship and finish is naturally of the same high class as all the other cameras of this make. The price is £4 10s.

A Spring Handle. T. T. Griffin and Sons, Limited, Kingsway, London, W.C.

Messrs. Griffin and Sons send us a sample of a very simple spring

ndle for holding the brush for the Rawlins oil printing processes, which considerably facilitates the "hopping" process, which seems to be so necessary for some effects in this work. The method of using this is shown in the illustration. The price is 6d.

They also inform us that they have now ready burnt umber and ochrean red pigments, in addition to the black, so that a much wider range of tints is now available. Other colours are also shortly to be introduced.

Messrs. Griffin are also putting out trial outfits for this process at the following prices:  $\frac{1}{4}$ -pl., 3s. 6d.;  $5 \times 4$ , 4s.; and  $\frac{1}{2}$ -pl., 4s. 6d. These outfits will comprise one packet oil pigment paper, one tube of pigment, one No. 2 size brush, one palette, knife, six pieces of specially prepared blotters, and one copy of the instructions.

The Tress "Studio" Reflex Camera. Made by the Tress Company, 42, Oxford Street, London, W.

This camera, which is specially intended for studio work, comprises a most distinctly novel idea. The reflector is at the side of the camera, so that the camera may be used on a stand of any height. The reflector

is of square form, so that it can be used both for vertical and horizontal pictures. The camera is fitted with a reversing back, swing rising front, and the use of a focussing cloth or shutter is entirely omitted, as the reflected image can be seen even in a bright light, the exposure can be made by swinging the mirror out of the way and letting it fly back.

The idea embodied in this is excellent, and it should be of considerable use in the photographing of children, etc., in which it is desirable to watch the image which will be thrown on the plate, so as to get a good pose. Fitted with one dark slide and an extension of 4 inches, the price for half-plate size is £3 17s. 6d.

## New Materials.

Imperial N.F. (non-filter) Orthochromatic plates. Made by the Imperial Dry Plate Co., Ltd., Cricklewood, London, N.W. In reviewing this introduction of the Imperial Co., which we now know after some considerable use of the new plates, it may be well to refer to the company's presentation of an orthochromatic plate dispensing with a light-filter, to say that such an introduction is, of course, by no means impossible. It seems almost needless to make some statement, because so much has been said in the past about the foolishness of using orthochromatic plates without a correcting and adjusted yellow filter, that the idea may be fixed itself in the mind of some that such advice was pernicious, whereas, of course, it only applies to things as they exist or

have recently existed. The production of a plate which, without any filter, shall give precisely as good colour-rendering as the most perfectly adjusted plate and filter at present is merely a technical problem of producing a suitable emulsion or of combining the screen in some way with the plate itself. A most difficult problem, we admit, but yet one which no one believes to be incapable of solution. We can, therefore, approach the announcement of the Imperial Co. free from any bias, born of the undigested pronouncements on current practice.

We are bound to admit that in the new N.F. plate the degree of yellow-sensitiveness imparted to the plate is raised to a point which we have never found before in a commercial plate. We have no occasion to inquire how this effect is obtained, though it would seem that it is produced by a screening action of a dye in the film itself, a self-contained light-filter which during development and fixation washes out of the plate and leaves it clean and free from stain of any kind whatever. We wish to emphasise this point because we have come across dyed plates which required somewhat more than the ordinary treatment to rid them of colour.

In speed the N.F. plate does not profess to rival its brother, the "Imperial" Special-Sensitive "Orthochrome," but it is nevertheless of such sensitiveness that snap-shot exposures running to 1-25th of a second at a lens aperture of  $f/6$  have given us well-exposed negatives of portrait subjects using the "Imperial" pyro metol developer in the ordinary way.

One point we should not omit to mention, and that is the notable freedom from halation of the negatives, a result apparently of the screening action of the dye in the plate. This may or may not be the case, but the general conclusion from a use of the plates must be that in them the Imperial Company have given photographers a plate in which an excellent rendering may be obtained without any screen, a statement which leads to the obvious corollary that in using a screen for subjects of great range of colours in which the highest degree of correction is required the increase in exposure will be very much less than with a less orthochromatic plate.

The following are the results of measurements of the plate made by Dr. S. E. Sheppard:—

Inertia (to screened acetylene and with H. and D. pyro-soda) .35  
 $\infty$  (measuring the density-giving power of the plate) 2.62 K (velocity constant of development with standard ferrous oxalate at 20 deg. C.) .070.

$\gamma_1$  (time to reach a gamma of 1 in standard developer) 5.4 mins.

X (blue-sensitiveness—yellow-sensitiveness equals 1.1.

Like the "Imperial" Special-Sensitive "Orthochrome" plates, the "Non-filters" are sold at the popular prices of 1s. per dozen quarter-plates.

"Lotos" Stripping Film for Collodion Negatives. Made by Mawson and Swan, Newcastle-on-Tyne.

Referring to our paragraph in the review of Mr. Arthur Payne's book last week on his new process of stripping collodion negatives, we have now practically tried this and find it works exactly as described. It is recommended to use a talced glass for coating the plate when making the negative in the first place, but we have found the collodion strip, even without taking this precaution, the glass being merely well cleaned and rubber edged. For many purposes these stripping films will be most useful, as it will enable the negative to be printed either as a reversed negative or not, so that one can make a silver print or a carbon print at will from the same negative without any further trouble, and they will also be found extremely useful in photomechanical processes, such as photogravure and collotype, and processes where reversed negatives are essential. The film appears to consist of flexible gelatine, and answers in every respect the same as a negative coated with liquid gelatine on a levelling slab, which is a process requiring some amount of skill to do satisfactorily. It is recommended after the film is dried on the negative to coat with plain collodion, and this is certainly a sensible precaution, as it will prevent moisture from attacking the film, and it will therefore not be so liable to get finger-marked, as if left without any protection; although, with careful use, there is no reason why the negative should not be thoroughly serviceable without this. The films will be sold in two sizes,  $15 \times 10$  at 3s. 6d. per dozen and 2s. per half-dozen sheets; and  $15 \times 20$  at 6s. 6d. and 3s. 6d. per dozen and half-dozen sheets.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JULY 6.

Borough Polytechnic Photographic Society. Outing to Strand-on-the-Green.  
North London Photographic Society. Outing to South Mimms.  
Bowes Park and District Photographic Society. Outing to Ware.  
Bristol Photographic Club. Outing to Shirehampton.  
Southampton Camera Club. Launch Trip up the Beaulieu River.  
Worthing Camera Club. Outing to Amberley and the Arun.  
Hull Photographic Society. Outing to Hawden.  
North Middlesex Photographic Society. "Record" Outing.

MONDAY, JULY 8.

Everton Camera Club. Evening at Docks.  
Southampton Camera Club. "Trimming, Mounting, and Finishing the Print."  
W. K. Kay.  
Bradford Photographic Society. "Discussion on Negatives." F. Nicholson.

TUESDAY, JULY 9.

Hackney Photographic Society. Formal Opening of the New Headquarters.  
Address by the President, followed by a Display of Members' Work.

WEDNESDAY, JULY 10.

Rugby Photographic Society. Outing to Charwelton and Badby.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Annual general meeting, June 27, 1907, Mr. T. E. Freshwater in the chair. The hon. secretary's report, which showed a slight fall in membership, was confirmed, as was the hon. treasurer's balance-sheet. The following lectures, among others, were named in the report:—"Madeira Up-to-date," A. L. Henderson; "A Scientific Chat," A. Haddon; "Photographic Notes," T. E. Freshwater; "Here and There in Great Britain," J. T. French; "Rendering of Colour and Colour Contrasts," Dr. C. E. K. Mees; "Through Holland," F. Slater; "Bathed Plates and Ortho Work to Date," A. J. Bull; "Improved Process of Development," D. W. Hart; "Colour Printing," O. S. Dawson; "Dry Plate Lantern Slides," J. S. Teape; "Wet Plate Lantern Slides," H. C. Rapson; "Modern Printing Processes," Archer Clarke; "Selection of Apparatus," Ernest Human; "Stand Camera Work," H. C. Rapson; "Carbon Printing," Ernest Human; "Gum Bi," H. Stuart; "If," Ernest Human; and "A Chat on 'Colour Photography,'" W. T. Wilkinson. The following were elected officers for the year:—Trustees, Messrs. Freshwater and Haddon; committee, Messrs. R. Beckett, J. T. French, A. E. Smith, J. S. Teape, H. C. Rapson, W. R. Stretton, W. G. Holman, W. Thomas; hon. lanternist, Mr. G. T. Wright; hon. librarian, Mr. W. J. Ferry; hon. secretary, treasurer, and recorder, Mr. Ernest Human. We may note that the last-named gentleman's address, to which all communications should be addressed, is 43, Whitta Road, Manor Park, Essex.

## Commercial & Legal Intelligence.

SUNDAY TRADING.—At the Cleethorpes County Police Court last week, before the Rev. Canon Quirk (chairman) and other magistrates, an interesting case under the Sunday Observance Act was heard. The defendant was John Hawkey, photographer, who was summoned for following his ordinary occupation on Sunday, the 16th ult.

Mr. Barker appeared for the defendant, and pleaded not guilty.

Deputy Chief Constable Stennett said that the defendant was a photographer, and occupied a shop in Cleethorpes. He had not for some years opened his shop on Sunday, but he had resumed opening and came there to test the case. When the inspector waited upon him he raised two points. One was that on week days he took photographs himself, but on Sundays his wife did that, so that he did not follow his ordinary calling. Therefore he thought he was not liable. His second point was that he was an artist and did not come under the jurisdiction of the Act.

Inspector Sindall said that on the 16th ult. he saw defendant against his studio and calling out the prices. He saw people going in and out, and he went up to him and said that he saw he was carrying on his business as usual. Defendant said, "Oh, no, not as usual; my wife is manipulating the camera and taking the money, and I am simply calling the prices. I am not carrying on my ordinary

calling. You cannot proceed against my wife, because she is a housewife." He was doing the same as he did on ordinary days in touting for custom.

Mr. Barker submitted that there was no case against his client, he simply stood at the door and invited people in; he took no photographs and did not follow his ordinary calling, which was that of an artist. He read the opinion given in the legal columns of a newspaper, which was to the effect that if a man took a photograph on a Sunday he sold it on the same day he made himself liable, but if he merely took the photograph and sold it during the following week he was an artist, and was outside the statute, and could not be summoned. He submitted that as his client had not taken a photo, or manipulated the camera in any way he could not be said to be following his ordinary calling. He was not summoned for touting, which could not be called his ordinary calling. His client was quite frank about the matter, he wanted to evade the Act. His points were, first, that he was not following his ordinary calling; and secondly, that he was not a tradesman within the meaning of the Act.

Defendant was then called, and said that he ought not to be classed as a tradesman; he was an artist. All he did on a Sunday was open his studio, and stand on the doorstep and invite people to have their photos taken. He took no part in manipulating the camera, posing, developing, and in no way followed his ordinary calling.

The Chairman said that Mr. Barker had fought his case very ably and had raised every possible point, but the unanimous opinion of the Bench was against him, and there would have to be a conviction. Defendant would have to pay 5s. and 5s. 6d. costs.

A PHOTOGRAPHIC METER ACTION.—At the Wrexham County Court last week, his Honour, Judge Moss, heard a claim for £52 10s. brought by the Infalible Exposure Meter Company (of which Mr. G. F. Wynne is managing director, as well as the inventor and patentee of the "infalible" exposure meter, against Messrs. Woodall and Parkinson, Lever Street, Manchester, with Messrs. Stahlecker, of Finsbury, London, as a third party.

Mr. Graham, barrister, appeared for the plaintiff; Mr. F. Brocklehurst was for the defendants; and Mr. Louis Green represented the third party.

The claim was for damages for breach of contract for the sale and delivery of 20,000 meter cases, and the number of cases in respect of which the claim was made totalled 2,103. The sale was by sample and the damages were claimed because the goods when delivered were not equal to sample, and were utterly useless for the purpose for which they were supplied. The plaintiffs are proprietors of a patent which they called the Infalible Exposure Meter, an article, like a watch, which enables a photographer, by turning a dial and watching the effect upon a fine, sensitive paper, to tell what exposure he should give in photographing an object under varying conditions of actinic light. The plaintiff's case further was that the meters claimed for were defective, either as regards loose pendants, which came off with ordinary pressure, loose snaps, or dints in the metal. The dial, sensitive paper, and other fittings were inserted in the case at the plaintiffs' works at Wrexham. A considerable number of these alleged defective cases, though not quite so bad as the others which were withheld from the market, were sold to customers, but in most cases were returned as useless. The models were of German silver, and plaintiffs expected the goods supplied by the defendants to be of the same metal. As a matter of fact, however, the plaintiffs alleged that they were all made of brass nickelled over, so that the difference could not be detected.

The defendants' case was that they gave the order for the manufacture of the cases to Stahlecker's Agency, who were the third party to the action, and, without examining the goods in any way, relied upon Stahlecker to supply a useful and durable article. Cross-examination on behalf of Stahlecker's was directed to show that Messrs. Woodall and Parkinson, without plaintiffs' knowledge, agreed to the substitution of brass for German silver. The further hearing was adjourned.

SUNDAY TRADING.—Charles Brooks, photographer, of 506, Mile End Road, London, was summoned for opening a booth on Midsummer Common, Cambridge, for business on Sunday, June 23.—Police Sergeant Free said he saw some lads in the act of being photographed by the defendant in his booth on Sunday. The door of the booth was secured. Defendant told witness that he took the young men's photographs on the previous day, but, as they did not come out right, he

king them again without charging for them.—Detective-at Marsh said the defendant asked him to have his photograph on the Sunday in question.—A young man, named Arthur Kent, Gold Street, said he was going to have his photograph taken the constable went in. Witness did not have his photograph the day before.—Defendant, who said he was in the habit of his booth on Sunday, was fined 2s. 6d. and costs, 11s. 6d.

INGEMENT OF COPYRIGHT.—At Carlisle Assizes last week a of infringement of photographic copyright was brought by ick Nainly, photographer, against Messrs. Beaty, printers, s. No penalties were claimed by the plaintiff, who only sought es, and judgment was given in his favour to the amount of £5.

#### NEW COMPANIES.

ROME.—June 22. £25,000 (£1). To adopt an agreement with nly and to carry on the business of manufacturers of, and in, photographic apparatus and materials, etc. No initial issue. First directors (not less than two nor more than seven) ppointed by signatories. 100 shares. Five per cent. of profits, e.

RS. CHARLES ZIMMERMANN and Co., of 9 and 10, St. Mary-at-ondon, E.C., inform us that they have formed their photo-department into a limited liability company, under the title res Zimmermann and Co. (Photographic), Ltd. The new y takes over all the agencies, contracts, and business of the ment, but the liabilities and assets up to June 29 remain with ere is no issue of shares to the public. There are no debent-All the staff have been retained. The directors of the new y will be Charles Zimmermann and Russell J. Kindon.

## News and Notes.

FEDERATION OF THE PHOTOGRAPHIC SOCIETIES OF NORTH-AND DURHAM.—A fairly large band of photographers d Morpeth on the 27th ult. and spent a delightful afternoon in aulful and historic neighbourhood. It was the annual field the Federation of the Photographic Societies of Northumber-and Durham, and the Morpeth Y.M.C.A. Camera Club had the ge of entertaining the members of the federation. The club tee, of whom Mr. James Whittle, the hard-working and astic honorary secretary, is the moving spirit, had arranged ractive programme for the day's proceedings, which was out in the main, and the outing proved to be one of the successful and enjoyable in the history of the federation. The apnic societies represented were South Shields, Blyth, New-and Northern Counties, Dudley (Northumberland), Blyadon, outh, Whitley, and Jarro, while a considerable number of ched photographers participated in the proceedings. At one the visitors were received by Mr. G. D. Dakyns, M.A., on of the Morpeth Y.M.C.A. Camera Club, in the Y.M.C.A. o Hall. Mr. Dakyns very heartily welcomed the visitors, and ed regret at the absence of Alderman G. B. Bainbridge, the nt of the association, than whom, he said, there was no more devotee of photography. Alluding to the excursions to Mit-bothal, etc., which were to take place in the afternoon, Mr. remarked that in this way the photographer learned incly a great deal of the history of his own country, and through asantment of mediums, that otherwise would, perhaps, never be Touching on the subject of the federation, Mr. Dakyns said o counties took a lot of beating in most things, and he t this applied not less to photography than anything else. He t they could claim for Morpeth that it was one of the jewels humberland, and perhaps he would not be wrong in saying e setting of the jewel was even more beautiful than the jewel Mr. Dakyns concluded by again cordially welcoming the y, who subsequently proceeded to the Castle Banks, where a photo was taken by Mr. A. B. Gardiner, of Newcastle. The afterwards divided into two parties, one going to Mitford e other to Bothal. The members were supplied with pro-cess containing information as to all the points of interest d in the respective tours, the matter for which had been

written by Mr. James Fergusson. The Mitford party was con-ducted by Messrs. C. F. Murphy, E. A. Smallwood, and W. L. Wilkinson. They were driven in brakes to Mitford, and the first halt was at the village smithy, where the obliging smith arranged an admirable little horse-shoeing scene. This provided good "material," and about twenty-five or thirty cameras were soon focussed and the scene duly taken. The church was the next object, and numerous photographs of the edifice (exterior and interior) were secured. The castle, tower, and manor house came in for similar treatment, the cameras being very freely used. Through the kind-ness of the Rev. R. C. MacLeod, vicar of Mitford, the members of the party were allowed to change their plates in his dark-room, a courtesy which was very much appreciated. The party afterwards explored the lovely grounds of the Hall, and proceeded on to the higher banks of the Wansbeck, whence such a delightful view of the castle and church is obtained. The Bothal contingent had an equally enjoyable time. This party was conducted by Messrs. L. A. Loades, E. Swinney, and J. T. Harrison. Various points of interest in the town were noted, and the party proceeded via East Mill to the Lady Chapel Wood, the walk through which was extremely pleasant Bothallaugh, by the kindness of the rector, the Hon. and Rev. W. C. Ellis, was visited, and the fine grounds inspected. The church and castle and grounds (by permission of Mr. Sample) also proved a source of delight to the party who, well "armed" with slides, made good use of their cameras, the day being a good one for the purpose. The two parties met in the town again, and proceeded to Messrs. Dance and Carr's establishment in the Market Place, where high tea was served. The members after-wards reassembled in the Y.M.C.A. Lecture Hall, where a concert took place. Dr. East, of Morpeth, was the chairman, and made some appropriate remarks. He expressed pleasure that the members had had such a favourable day for the outing, which he did not doubt they had enjoyed. The Morpeth Club, he mentioned, was going to award a silver medal for the best photograph taken during the day, and Mr. F. J. Mortimer, F.R.P.S., the editor of "Photo-graphic News," had kindly consented to judge the prints. The members of the Morpeth Club, said the doctor, intended to carry off the prize if possible, "but," he added, "if it goes to another club we shall be the first to congratulate them on beating us on our own ground." The doctor subsequently made reference to the com-plement which had been paid to the Morpeth Club by the election of Mr. Whittle as secretary of the federation. Morpeth, he went on to say, was rather neglected as a centre for photographers, and he thought the Newcastle and other clubs would be more than repaid by coming out a little oftener to pursue their art in such an ideal neighbourhood. He concluded by expressing the hope that the members had thoroughly enjoyed their visit to Morpeth, and that it would not be the last occasion of the kind under the auspices of the Y.M.C.A. Camera Club. An address was to have been given by Mr. Walter S. Corder, chairman of the federation, but, being absent through illness, his place was filled by Mr. Arthur Payne, F.C.S., of Gateshead, through whose efforts the federation was founded in 1901, and who was secretary for several years after its inception. Mr. Payne made complimentary references to the Morpeth Camera Club and to Mr. Whittle, and went on to give his views on what he considered to be an ideal federation. The essen-tial factor, he urged, was co-operation between the various societies, and a proper and enthusiastic support of the officials, which unfor-tunately was not unfrequently lacking. He also spoke of the advan-tages offered by the federation to photographers in all branches of the art. During the evening musical items were rendered by Miss Grace Angus, Mr. Chas. Wilkinson, and Mr. C. F. Murphy, Mr. A. Platts, A.C.M., being the accompanist. Votes of thanks to Mr. Payne, the artistes, the Y.M.C.A. Camera Club, Mr. Whittle, and the chairman concluded a most enjoyable day's proceedings.

NOTICE OF REMOVAL.—The Brighton Photographic Company announce that, owing to the need of larger premises, they have removed their works from 57 and 58, Clarence Square, to 90, Preston Road, Brighton, where all communications should now be addressed.

THIS week a photographic weekly offers hints on "taking oneself." Of course, says the "Evening News," the great thing is to look pleasant. So many amateur photographers make the mistake of taking themselves much too seriously.

**THE ANNUAL OUTING OF THE CITY SALE AND EXCHANGE.**—The employees of the City Sale and Exchange visited Maidenhead, on the occasion of their seventh annual outing, on June 29. Leaving train at Taplow the party, to the number of fifty-eight, had a pleasant walk to their headquarters for the day, where dinner was served, Richard Green, Esq., C.C., the proprietor of the firm, presiding. This having been done full justice to, the usual toasts followed, the president proposing that of "The King," followed by that of "The Queen," "Prince and Princess of Wales," and "The Royal Family," referring to the interest taken by the Queen in the Lord Mayor's Cripples' Fund, as instanced by her presence at the recent bazaar to accept purses of money collected by some thirty children in aid of the fund. Mr. Birk, of the Lime Street branch, proposed the health of Mr. Green, with which he coupled the name of Mrs. Green. Mr. Green was, he said, a good master, and one whom every assistant should endeavour to make a friend of, because, if he was a good master, he was, if possible, a better friend, and he felt sure that, from his experience of him, he had the welfare of each employee, from the youngest to the oldest, at heart. Mr. Green, in replying to the toast, caused much amusement and laughter by remarking that Mr. Birk had, he thought, missed the grip of his toast—namely, his (Mr. Green's) health; he had spoken of everything but that, but he thanked those present for the kind expressions which they had conveyed through Mr. Birk, and hoped that he was as much their friend as master. He, personally, did not like the word "master," because, had it not been for the loyalty, help, and assistance of his various employees, he was sure that the business would never have reached its present dimensions, and he wanted, for that day, at any rate, the party to become somewhat of a socialistic character, and for all to forget that there were such words as "masters, managers, and heads." To the general manager of the Fleet Street branch fell the toast of "The Firm." He said that, as was well known, since the last occasion of such a gathering, the firm had extended by the opening of a new West-End branch at Chelsea, which he hoped would be as successful as the older branches had been. He was perhaps the oldest employee present, having been with Mr. Green some seventeen years, when the only branch of the City Sale and Exchange was the downstairs shop at Lime Street. Mr. Gilbert spoke on behalf of the Aldersgate Street branch, whose manager was an absentee; and Mr. Wood, on behalf of Lime Street, whose manager, Mr. John Green, was unable to be present owing to illness. It was somewhat unfortunate that during dinner a heavy thunderstorm came on, but by the aid of a piano and some of the more musical of the party, a most enjoyable evening was spent, and after tea, which was served at eight o'clock, an hour on the river, or a pleasant walk, brought the day all too soon to a close, the whole party leaving Taplow at 9.53, very tired, but very happy.

#### CATALOGUES AND TRADE NOTICES.

**SPYERS AND POND, LTD.**—Those in search of bargains should visit Messrs. Spiers and Pond's photographic department, Queen Victoria Street, E.C., during the great summer sale, which is now in progress, where cameras, lenses, tripods, and photographic accessories and materials in general are being offered at greatly reduced prices. The list contains a number of high-class instruments, which are listed as being "shop soiled," a fact which, whilst it in no way detracts from their utility, considerably reduces their price, and renders it possible for many to obtain a really good piece of apparatus who could not afford the original price. The list is well worth a careful perusal by those desirous of purchasing anything photographic.

**CARL ZEISS, Jena**, whose London address is 29, Margaret Street, W., send us a pamphlet describing their special tele-objective, and setting forth the exposures and subjects for which it is specially adapted, with directions for its use.

ANOTHER prosecution has just taken place in Dublin under the Merchandise Marks Act for the sale of washing soda. One sample was adulterated to the extent of 27 per cent. and another to 40 per cent. of Glauber's salt, or sulphate of soda.

**CHANGE OF ADDRESS.**—Messrs. R. Wilkinson and Co., the well-known firm of postcard publishers, have removed from Church Street, where their business has been carried on for a number of years, to larger and more convenient premises in the Market Place, Trowbridge, where all future communications should be addressed.

## Correspondence.

\**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\**We do not undertake responsibility for the opinions expressed by our correspondents.*

#### DARK ROOM FILTERS.

To the Editors.

Gentlemen,—In the most interesting paper of Dr. Mees on "Dark Room Filters," in your last issue, the following sentence occurs:—"Having had several requests for a special light from friends of ours, who can either scarcely see red at all or to whom the red light is extremely irritating."

But is it not the case that even those whose eyes have normal refraction and whose colour sense is perfect, find it impossible to see distinctly in red light by reason of the non-achromatism of the normal eye? Here is a factor which, so far as I know, has not been neglected in discussions relating to dark-room illumination.

It is a well established fact that the normal eye cannot sharply on the retina red light diverging from objects at short distances from it, say at distances comparable with the distance of distinct vision. For fairly divergent pencils of red light the normal eye has not enough refractive power, or, to put the matter in another way, the normal eyeball is too short. In a word the normal eye is long-sighted for all red objects not far removed from it. Hence, to work in comfort in red light it is necessary to appear advisable to wear convex spectacles of greater or less power according as the eyes are long-sighted or normal. The adoption of such spectacles might allay some of the "irritation" referred to in the passage quoted from the paper.

A normal-eyed person may easily convince himself of the fact that he is long-sighted for red light by attempting to read through one or three thicknesses of ruby glass print held at the normal reading distance from the eye. The print under such conditions is so blurred as to be almost, if not perfectly, illegible. The interposition of a weak convex lens between the eye and the print at once remedies the matter.—Yours faithfully

DOUGLAS CARNEGIE

Blackheath.

#### THE EFFICIENCY OF IRIS SHUTTERS.

To the Editors.

Gentlemen,—I have always associated myself with the practical side of photography, and not with the scientific side, and I am grateful to Mr. Welborne Piper for his cone theory of diaphragm shutter speed measurements, which is obviously correct. I must, my readers, therefore, to multiply the exposure given by a diaphragm shutter, during the period it is opening and shutting, by  $\frac{1}{2}$  in order to arrive at the efficiency. Fortunately, my error of little or no practical importance, for the example I give on page 424 works out as follows:—Supposing the total duration of exposure were 1.30 sec., and 1.60 sec. was spent in opening and closing, and 1.60 at full aperture, then the efficiency works out to 1.60 sec.  $\times$   $(1.60 \times \frac{1}{2}) = 1.45$  sec., and not 1.48 sec., as I originally gave it.

However, I part issue both with Mr. Welborne Piper and Mr. Chapman Jones when they take the action of diaphragm shutters stopped-down lens into consideration, for it is the argument of the scientific, and not the practical photographer. I cannot conceive a practical hand camera worker, with a decent lens of the conventional focal length, stopping down beyond  $f/8$ , and Mr. Piper's supposition that a hand camera lens stopped down to  $f/64$  does not come within the realms of practical photography. Assuming that a practical photographer were photographing a figure near the camera, would he not rather that the distance was just sufficiently out of focus to throw the figure into bold relief? Assuming that the illumination of the subject would permit the lens to be stopped down to  $f/25$ , would not the up-to-date photographer open out to  $f/8$ , and employ a tent or black screen?

I always feel that scientific men do comparatively little for practical workers, and I feel that it is hard that a practical photographer, myself, should have to come forward to advocate a method of efficient exposure measurements. Obviously these remarks do not apply to either Mr. Piper or Mr. Chapman Jones, who have done so much

practical side of photography. The fact remains that one diaphragm shutter with erroneous speed markings; one sends scientific firm to be tested, and one receives, not the actual of the various exposures, but the total duration of the from start to finish.—Yours, etc., A. J. ANDERSON.

#### TRIAL DEVELOPMENT FOR PANCHROMATIC PLATES.

To the Editors.

men,—May I point out that panchromatic plates are free and successfully developed by the factorial plan? Instead of the plate itself to inspection and so causing fog, a slip of the same brand, impressed with a standard high-contrast, is dipped in the developer and the time of appearance This can be done in quite a copious orange light, as any fog will not make its appearance until after the high-light, when having served its purpose, is thrown away. The time of exposure is multiplied by the usual factor, and the true plate is developed for this time in total darkness. One plate exposed to for the time right for a landscape will cut up into a number of strips. The trial plate is partly masked with a grating in the developer. This plan is fully explained in my manual.—Yours ALFRED WATKINS.

#### "TIMES ARE HARD."

To the Editors.

men,—Yes, undoubtedly so. Why, and with whom does the blame rest? Mr. Bridge's suggestion is good, but unfortunately too late. Some fifteen years ago attention was called to the decay of the profession becoming, as it is now, almost ruined by the invasion of a certain class of most undesirable men. No warning was taken of the warning, and now to-day, what is the state of the profession? At that time "Tanqueray" was the only man who was known for carrying on his "illegal swindle." At the present time he has hosts of the same crew in the country. Their name is legion. Every city, town, and village, from north to south, from west to east, has been visited and attacked by swarms of men, men too, in the employ of these most unwelcome visitors. This means the very name of photography in any shape or form is a disgrace to the nostrils of the people; and as to who these individuals are, a visit to Scotland Yard would probably enlighten you as to the professional. Not only have we now to thank the utter lack of a system of trade protection, but the intense and fatal mismanagement has been made in pandering to the so-called amateur. Look at the ungraceful cutting of prices that is constantly occurring; every branch and department of the trade has been attacked by this monster. What for, and for whose benefit? There is not a demand for it, has been, the slightest demand from the public in that but only has it originated among a certain class of men, the "pool," totally and utterly regardless of what injury it inflicts on others. And who is to blame in a great degree for all this? At all possible for anyone to attempt such doings? Why, the man who in many instances have sprung into existence by the aid of the professional, and now, to show their gratitude, assist a lot of insignificant nobodies, who, frequently obtaining a regular weekly income from other sources, get supplied with cheap outfits, etc., placing them at the very first start to completely undersell the professional.

I had been given to the warning already referred to and a system of trades unionism and protection then founded; the evils mentioned could never have come into existence; regard to the "free portrait dodge," no firm in the recognition has been benefited in the slightest degree, because the various departments in that have been in the hands of a clique, and any local photographer can soon satisfy himself of the component parts of that clique. It is most difficult now to find a way out, a remedy, as the profession, by reason of its lack of unity, has to a very large extent brought matters to a standstill. Where is it going to end? Is the professional to be driven out of existence entirely to make room for the so-called amateur? It must be borne in mind that the ruinous rates of the dozen midgets at 6d., or ditto postcards at 1s. 10d., were inducements for men of brains and talent to become, or to be, professional photographers.—Yours truly,

UBIQUE.

## Answers to Correspondents.

- \**All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.
- \**Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- \**Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*
- \**For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

#### PHOTOGRAPH REGISTERED:—

MacLucas & Co., The Excelsior Studio, Vaughan Street, Llanelly. *Photograph of the Interior of the Parish Church of Llanelly.*

E. HERRIDGE.—No, it would not be legal, as you would be obviously running a lottery.

H. J. MORAN.—We do not answer queries by post. Bleach your bromide in the ordinary mercuric chloride solution and wash and dry. Immerse the tape in hypo solution and dry.

REFINER.—1. This depends entirely upon the plate, probably about 1½ oz. 2. It will not settle unless you precipitate it with liver of sulphur. 3. Either liver of sulphur or else zinc filings.

T. ROBERTS.—You might be able to obtain the glass from Newton and Co., Fleet Street, London, E.C.

G. R. E.—So far as we are aware, nothing has appeared in English. Both Marey (French) and Eder (German) have dealt with the subject cursorily. It was also dealt with at one of the International Congresses at Paris about ten years ago.

A POINT IN COPYRIGHT.—A client wants photograph of self taken and proof submitted before giving an order or paying anything. I have done this, but heard nothing further. What I want to know is to whom does the copyright belong?—A. G. C.

This is rather a difficult point, but it may be assumed that there is an implied promise to pay if the proofs are satisfactory. If they were so, then we should say that the copyright belonged to the sitter. If they were not, then as the photographer has received "no valuable consideration" the copyright belongs to him and not to the sitter.

AMERICAN JOURNALS.—Will you please tell me the best journal to reach professional photographers and dealers in America, also cost of small advert., like your "Situations Vacant" column. I know the question has been answered, but cannot find it on looking my old JOURNALS through; so if you would be so kind again you would oblige.—B. D.

The two best papers for this purpose would be "The Professional and Amateur Photographer," 220, Washington Street, Buffalo, N.Y., and "The Photographer," 154, East Twenty-Third Street, New York. The former is a monthly, the latter a weekly.

COPYRIGHT.—In February last an amateur theatrical society gave a performance of the "Yeomen of the Guard," assisted by a professional as leading lady. We asked this lady to give us a sitting as Phoebe at the spinning wheel. She did so, and we presented her with copies. The first print from the negative was registered, and every copy was stamped copyright. Since then an enlargement has been presented to the said lady by a member of the society. Will you kindly let us know if we have a case against that member, as we cannot ascertain who copied our photograph?—ARTIST.

On the old legal axiom, "Qui fecit per alium fecit per se," or he who does a thing by means of another doeth it himself, the member of the society, if he or she caused the enlargement to be made, is obviously the person who has infringed your copyright. The actual enlarger was merely a tool, but he might, if found, be joined to the action.

F. DAVIDSON.—There is not the slightest doubt in our mind as to the cause of the marks. They are due to the cards being touched with fingers contaminated with hypo or some other chemical,

and this has happened before toning. We are returning you the cards, and have marked some with a pencil. If you hold these up to the light, just level with the eye, so that the light glances along them, you will see distinctly the fingermarks on the surface. Under the circumstances, we should advise you to apologise and pay.

**COPYING PLANS, ETC.**—Will you kindly inform me whether there is any method of obtaining a reproduction of a plan, say, from a book with letterpress on the reverse side, other than by the ordinary photographic use of camera and plate? Of course, ferro prussiate paper would answer were it not that the printing from the other side would show through.—J. C. G.

The only suggestion we can make is that possibly Playertype would answer. Place the engraving face up and lay on it a sheet of bromide paper. Press into contact and cover with a green, yellow, or red glass. Mr. Player states that three thicknesses of yellow tissue paper between glass is the best screen, and this should be held about nine inches above the paper and about three inches under a bright gas. The exposure will vary from three to six minutes, and develop with

Hydroquinone .....	3 grains.
Sodium sulphite .....	12 grains.
Sodium carbonate .....	24 grains.
Water to .....	1 ounce.

Development is carried on until the image at first visible is buried. The result is a negative. This is rather a difficult process to carry out successfully.

**COPYRIGHT.**—I have been served a very dirty trick by a family here—they are known as being the meanest people in the place. They brought two children to have their portraits taken, cabinet size, at 3s. 6d. each, which they paid. At the same time they said that if the pictures were good they would require a good number of copies, and I took extra pains with them. Now I find that they have taken my pictures to a cheap photographer at — and ordered a dozen copies of each, as well as 20 x 16 enlargements. I naturally feel sore in the matter. Will you please tell me if I register my copyright in the pictures I can stop the other photographer from executing the order?—ILLUSTR.

No you certainly cannot, as you have no copyright in the pictures. You were paid for taking them, and the copyright belongs to those who paid you for the work. It is, as you say, very annoying; but it is a thing that has to be put up with in business.

**POSTCARD DEVELOPER.**—I wrote to you on the 19th ult *re* a difficulty which came under my notice when using a strong solution of metal-hydroquinone developer. Will you be able to give your advice in this week's "B.J.P." Correspondence; also, if you can, recommend me a developer giving good blacks, for use with large quantities of postcards (bromide), with a view to economical working? I am using a standard formula with every satisfaction, except that I think for postcard work there may be a formula more economical.—ENQUIRER.

If the query was received it would have been answered, but we cannot trace it. With regard to the postcard work there is not much to choose as regards cost in the developers. Possibly the following might suit:—

Amidol .....	50 grs.
Sodium sulphite .....	650 grs.
Potassium bromide ..	10 grs.
Water .....	20 ozs.

This must not be kept longer than three days.

**FAULTY LENS.**—I enclose prints from three negatives taken with a half-plate lens I have just bought. You will see that it only covers about 5 x 4, although I used a *f*/11 stop, and lens is said to cover the plate thoroughly with the full aperture *f*/8. Can you tell me what I can do to make it cover better?—C. A. J.

It is evident that the lens has a very round field, and you will only get detail at the margins of the plate by using a very small stop—probably *f*/32, or smaller. What we advise you to do is to return it to the seller and get him to exchange it for a better one—one that will cover the half-plate. This you have the right to expect if the lens was sold as a half-plate one.

**Poisons, Etc.**—(1) Can a photographer sell a combined toning and fixing solution which contains sulphocyanide of ammonia and

acetate of lead, or, being poisons, can they only be sold to qualified chemists? (2) I have had an additional showcase fixed to my premises, and I have been told by a surveyor to remove same, or they will. Can they remove it, as I could easily make same so that it was a fixture? Next door a man has had a similar case fixed, and one has made any complaint. Thanking you in anticipation of an answer in your valued columns.—URGENT.

(1) Anyone not a chemist can use and sell sulphocyanide lead salts, as they are not included in the Poisons Act so

(2) In this case we are unable to advise, as we cannot say whether the showcase is a structure within the meaning of the law, whether it projects beyond the line of the building. Presumably it does. Then the point is, to whom does the forecourt belong? If it is yours, and you have to keep it in repair, then it is your private property, and you can do what you like. If it is not your private property, then the best thing to do is to remove it, as the L.C.C. inspector tells you—that is, assuming of course, you do not want a long and costly fight in the law courts.

**SKIN TROUBLES.**—I have a little difficulty with my fingers, in connection with the use of hypo in solution. After having fixed for a short time a small white blister appears. In a day or two after the skin cracks and causes my hands to be very sore. I have tried several things, but do not seem to do much. Is there anything that could be put in the fixer to prevent the blistering without taking away the usual fixing properties? Could you recommend a lotion or ointment that will cure same? I have been in the profession several years and now in a good position that I would not care to give it up. I use finger-stalls as I can.—FINGERS.

We have very grave doubts whether it is the hypo. In this case, we believe, the first case recorded of it affecting the fingers. You do not state whether you are using metol as a developer. The complaint looks very much like it. Possibly the use of chrome alum and bisulphite bath, or an addition of boric acid to the sulphite might be very beneficial. The following ointment should be of service:—

Ichthol .....	10 grs.
Lanoline .....	40 grs.
Boric acid .....	40 grs.
Vaseline .....	30 grs.

Apply two or three times a day, and rub in well before resting for the night.

**ANXIOUS ONE.**—We are afraid you must accept what was said, as sufficient notice, which would expire at the end of the week, is not absolutely necessary for a date to be mentioned.

**PHOTOGRAPHER DROWNED.**—A sad drowning fatality is reported from Blackpool, three visitors, supposed to have come from the north, being drowned on June 25. One of the party, a young man, walked down the steps leading to the sands to take a photograph when she was washed into the sea by a big wave. Her brother, her sweetheart jumped in after her, but failed to bring her up, and, after being dashed against some woodwork, disappeared the eyes of hundreds of spectators. The three bodies were eventually recovered, but have not yet been identified.

**\* \* NOTICE TO ADVERTISERS.**—Blocks and copy are received to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Photographic Convention opens at Hereford on Monday next, A portrait of the President, Alfred Watkins, J.P., p. 516.

to obtain firelight and lamplight effects by daylight is by Mr. Essenhigh Corke. (P. 518.) A supplement of the effects obtainable are given with this issue.

T. Harris describes his method of stand development with which should be read in connection with the article by Mr. last week's issue. (P. 520.)

practical hints on sulphide toning are given (p. 523).

udden death of Mr. A. L. Henderson is recorded this week. ent portrait of him is given. (P. 514.)

sketch of the late Dr. Czapski's life appears with portrait.

ling of postcard and other negatives is practically treated.

patent for reproducing plans, etc., is fully described, the ing a gum-ferric film. (P. 524.)

elborne Piper continues the discussion on the efficiency s shutter. (P. 530.)

respondent suggests a new remedy for poisoned fingers.

## EX CATHEDRA.

### The Martian Canals.

Popular opinion, led by the statements of astronomers that Mars is much in the same condition as our earth, is that this planet is inhabited. How far Mr. H. G. Wells is responsible for the universality of this opinion we are not prepared to state. Just now, however, Mars, being in opposition, is particularly favourably placed for both visual and photographic observation, and Professor Lowell, of Flagstaff Observatory, has dispatched an exhibition to the Andes and has himself, at Arizona, obtained some excellent photographs showing that the famous canals, which have been so much in dispute, have an objective existence and are not due to errors in focussing or defective eyesight. They were first photographed two years ago by Mr. Lampland, one of Professor Lowell's assistants, but the results now obtained are stated to be much superior. Naturally, these photographs do not prove that Mars is inhabited, but the regularity of formation of the canals precludes natural causes.

### X-Ray Plates.

For some considerable time there has been much doubt as to what exactly was the connection between the speed of a plate to light and its speed to the X-rays. At a recent meeting of the Röntgen Society this subject was dealt with by Dr. Kenneth Mees, and he comes to the conclusion that the speed of a plate to X-rays is proportional to its daylight speed; the velocity constant and the development law are the same and the shape of the curve is different, the X-ray curve resembling that of a plate which has no opacity to the light action, or, in other words, is transparent. In the discussion which followed his paper Dr. Mees stated that the X-ray plate had no inertia, but that this was obtained approximately by comparison with a plate exposed to light.

### Intensification with Mercury.

A writer in a contemporary recommends bleaching the negative with a solution of mercury bichloride and potassium bromide and blackening the result with sodium sulphide. This process is not exactly new, but an intermediate operation is recommended the purpose of which appears to be novel. After bleaching the plate it is "washed well" in running water and then laid for five minutes in a ten per cent. solution of common salt. The use of this is said to be "to precipitate the remains of the silver of the plate, replaced by the mercury bromide from the intensifier," which explanation we confess we do not in the least understand. There is certainly something wrong in the theory of the salt bath, which appears to be quite unnecessary. An acid bath to remove the last traces of mercury would be comprehensible and also generally advisable, but the

effect of the salt bath is not readily discernible, especially as it is applied after washing and immediately before the sulphide bath.

\* \* \*

### Colour Values and Colour Contrasts.

A great deal of discussion has recently taken place with regard to this subject, but few of the disputants seem to have been bold enough to admit the only logical conclusion, which is, that colour cannot be truly represented in monochrome. This fact would almost appear to be a truism, yet photographers do not seem inclined to admit it, probably because it seems to imply that their art-craft is incurably defective. It does not, however, imply anything of the sort. It simply directs attention to a limitation of the craft that should be of assistance as a guide to the best manner in which the craft should be employed. In this respect photography is much on the same footing as engraving. The engraver is limited in a very similar fashion, and upon this fact the greater part of the beauty of engraving depends. A method of expression peculiar to engraving grew up as a direct consequence of the limitation, and a somewhat similar method in process of growth is observable in photography. It is no part of the artist's work to attempt impossibilities, and if he does make such attempts, he only proves his incompetence as an artist. In photography it is impossible to differentiate between, say, a red and a blue of the same luminosity, and at the same time preserve the true luminosity values. An engraver can do it by varying the texture of his tints and shades, but not a photographer. At the same time, the engraver will seldom attempt to do it, because nine times out of ten it is quite unnecessary. In general, the contrast is of great importance, and the exact luminosity value of no importance whatever, and the contrast must suffer in the attempt to preserve the luminosity. The question then arises, which of the two colours should be shown as the darker one, and this must be decided according to circumstances. The final result is not a copy, but a paraphrase of the original, and the manner in which the paraphrase is to be effected must be left to the judgment of the artist. Photographers in general have instinctively tumbled to the fact that perfect correction of colour values is not always desirable, and that under, or even over, correction at times has advantages.

\* \* \*

### A Useful Addition to a Camera.

It has always seemed to us to be a curious thing that no camera maker ever puts a scale on the camera baseboard for the purpose of measuring or recording the extension. Focussing scales are common enough, but their use is limited. They are not very closely divided, and they are not long enough for the purpose of measuring extensions. When an ordinary camera is used for a variety of purposes, such as copying, enlarging, comparing different lenses, etc., a finely divided scale on the baseboard is frequently of very great service. It is, of course, advantageous for it to be arranged so that the actual extension from plate to lens node can be determined, but this can only be effected for one particular lens, and, in practice, we have found a simple scale arranged without any regard to position of plate or lens to be of very great service. We use a scale of inches sub-divided into twentieths, but a millimetre scale is perhaps most useful. Considering that the scale is only used to record positions of front and back of camera, and not the actual extension, the unit of the scale is of no consequence, so long as the re-divisions are sufficiently minute. The value of such a scale must be obvious, for it is often desirable to try variations in the adjustment of the camera, and by noting on the scale

the relative positions of the front and back, return to any particular adjustment with the facility. For example, the adjustment for a particular scale of copying is not always readily arrived at when the camera is once set the worker is reluctant to disturb it for the purpose of trying a different lens, or a different scale, even though such a further adjustment may be eminently desirable. With the scale there is no hesitation, seeing that the first adjustment is repeated quite easily.

\* \* \*

### Death of Mr. A. L. Henderson.

It is with extreme personal regret which we feel sure is shared by many friends, that we have to announce the sudden death of Mr. A. L. Henderson, at Bad-Near, on the 5th inst. Mr. Henderson was for many years one of the best-known figures in photographic circles, a constant contributor to our pages. His specialities were ceramic enamels; in the early days, too, of gelatin printing, he was a recognised authority on the subject. He was always ready to give assistance from his experience, which made him a valued member at all meetings, where he was never so happy as when in London.

[S. J. Beckett, Baker-street, W.]  
A. L. HENDERSON.

eager argument with one or all, and when his fiery enthusiasm frequently culminated in outbursts, at which himself was one of the first to laugh; notwithstanding this, he never carried outside the meeting room any personal feeling, and the regard and esteem in which he was held was proved by the attendances on those nights when it was known he was to speak or exhibit slides obtained in his travels necessitated during the later years of his life through ill-health. He was interred at Norwood on Wednesday last.

# PRINTING TITLES ON POSTCARD AND OTHER NEGATIVES.

The localised production and publication of postcards by the photographer, which none too soon has been taken up by those at last roused to its monetary possibilities, is a natural operation of printing calls for scarcely any departure from the ordinary routine of a studio; the photographer, however humble his establishment, has had to learn, saving only the final incorporation with the negative of a title which should automatically print on the postcard, either on a portion of the picture, in case the title is usually in white letters on the card, or on the white border underneath the card, in case it is invariably in black letters on the positive.

Although we have repeatedly given a short description of the method to be followed in performing either of the operations, requests for information which still appear to justify us in publishing a more detailed account of what is actually a most simple operation.

One may assume to commence with that the negative which the postcard is printed is of the half-plate size and is employed for the purpose, with the subject properly disposed upon it. It matters not whether the negative is an original one or one made from a photograph of transparency; the method is the same in either case. One will take first the second of the two cases mentioned above, namely, that in which the lettering is intended to appear on the white ground below the subject on the card, as it does in the numerous portraits of faces now upon the market. The necessary wording of the title is set up in type, and several good impressions are made in black ink on a white but not too shiny enamelled paper, the object being to obtain a very solid black which is less easily done if an "art" coated paper is used. In studios where a considerable number of subjects are being done as postcards it may be worth while to have a set of types and do the setting on the premises, usually we imagine it will be cheaper to employ a local printer. The impressions having been taken, however, are then photographed down to the desired size on a glass or photo-mechanical plate, on which the necessity of the ground and clearness of the letters can be ascertained without difficulty. The negatives having dried, comes the operation of transferring them to the post-negative. If the spot where the title should come on the negative happens to be fairly clear glass, all that is necessary is to transfer the title direct on to the gelatine of the process mentioned in the next paragraph; but if it is usually the case, the negative has no such clear spot, a strip of film is cut out with a sharp penknife, leaving a little space all round for the reception of the title.

Coming now to the actual method of transferring the title, these latter are cut up on the process negative with a penknife when the film is dry, and the latter is then exposed to the very rapid and easy stripping process described only a week ago (July 5) in these pages. Before exposing the title strip to the postcard negative the small portion of bared glass is painted with a little weak gum solution to secure the adhesion of the film. When dry, as is the case in about ten minutes, the negative is then masked off as shown in the illustration. It is usual to mark off the subject with Indian ink with a drawing and straight edge, as shown in the black line in the illustration. The further blocking-out is then done with a mixture, such as the Vanguard "Photopake," after being taken up as close as convenient to the subject. The stippled portion in the reproduction shows the "photopake" area.

Coming now to the case in which the title has to be printed on the subject portion of the negative itself, there

are several easier methods than the foregoing, depending on the use of rubber type, or thin opaque letters may be purchased and cemented to the negative. The strip method above described may also be employed when a tiny clear strip is obtainable, although it is usually preferable to employ a positive version of the original title negative,

in order to obtain in the final print a lettering in white letters on a dark ground, which looks better, in our judgment, than the black title on a strip of white ground, but the preference is a matter of taste and both forms can be seen on commercial postcards.

**PICTORIAL POSTCARDS.**—The Barton Pictorial Postcard Co., of 15, St. James's, Barton, Bristol, have sent us some specimens of their cards in plain and coloured collotypes, which are of very good quality. Special trade terms are given to professional photographers.

**W. BUTCHER AND SONS, LTD.**—Messrs. W. Butcher and Sons inform us that they have entered into an agreement with Messrs. Charles Tyler and England Bros., and that from this date the businesses will be amalgamated and carried on as W. Butcher and Sons, Ltd. The first directors are William Frederick Butcher, Frank Ernest Butcher, Charles Tyler, Isidor Joseph, and Alec. J. Jones, and the combined business will be conducted on the same lines as the individual businesses have been for many years past. The photographic card and mount factory will be carried on at Copenhagen Street as heretofore, and will be largely developed with the extra space and increased facilities at their disposal. All orders and correspondence previously sent to Charles Tyler and England Bros., Ltd., at Copenhagen Street, should in future be addressed to Camera House, Farringdon Avenue, London, E.C., where all books, manufactured stock, etc., have been transferred.

## THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

How rapidly time slips by us is never more apparent than when one has to draw attention to the meeting of the P.C.U.K., which takes place at Hereford next week. For it seems but a few weeks ago that we were looking forward under somewhat similar conditions to the meeting at Southampton this time last year.

During the previous twenty-one years of its existence the Convention has seen many changes, not only in the character of its meeting, but also in its personnel. There have been, as was inevitable, many sad gaps caused in its ranks by death, and many old members now do not attend, whilst still maintaining their active interest in it. There is, therefore, save for a few ardent enthusiasts, whom one always meets, quite a new set of faces to greet one. This is inevitable, and as it should be to some extent, for new blood is always essential. One has, too, at every meeting, local members who are seen, some for the first and last time, whilst others attend subsequent meetings.

It may possibly be permitted to ask whether that particular rule defining its aim and purpose is actually fulfilled. It runs: "The object of the Convention shall be the advancement of photography, and of the interest of photographers." Bitter criticisms have been directed against the Convention in past years, and probably will be again, but in almost all cases they have come from those who stand outside and fling mud at it, overlooking that the nobler part would be to join and try and improve matters.

Is it necessary, however, that things should be improved?

That the present policy as pursued by the council is generally approved is shown by the success of the recent meetings and the attendances. It is true that we have no epoch-making, startling papers, putting forward some facts revolutionary of photographic thought or practice. But how often during the last ten years

have we had such papers anywhere? There has been a general slow-creeping advance, and we must not expect that an assertion of average photographers is going to each year produce something phenomenal.

What the Convention has done and is doing is to cement the friendship of its members, whether professional, amateur, trade. It is broadening down more and more each year those barriers behind which each class had held itself. If it does it advances the interests of photographers. It has, is, providing opportunities for the interchange of thought, of knowledge, and experiences which make the advance of photography.

Where the Convention fails, and lamentably, is in the misuse of its funds which are now considerable, and increasing year by year. To use the term misadvisably, for it is practically, to give the old simile, wiping the talents on the napkin and burying them. Yet this failure cannot be laid down to the account of the Convention. It is entirely the fault of its members and others, though some years it may truly be said that the Convention has been lax in drawing attention to the fact

Photograph by

ALFRED WATKINS, J.P.,

Harold Baker.

The President of the Photographic Convention of the United Kingdom.

"The Council of the P.C.U.K. is prepared to make grant money in aid of photographic research."

The conditions now in force are as follows:—

1. An applicant for a Research Grant must present (a) a statement of the general nature of the proposed investigation and its object, with an abstract of any results that have already been obtained, and (b) a general statement of the way in which it is proposed to expend the Grant.
2. A Grant must not be expended on the purchase of permanent pieces of apparatus except by special permission of the Research Grants Sub-Committee.
3. The receiver of a Grant must make a general report of expenditure either at the end of, or during the progress of the

search, and shall then be entitled to receive either the whole grant, or such part of it as may have been actually expended. The receiver of a Grant must present a full report on his investigation at the first meeting of the Convention after the research is finished, and an interim report at any intervening meeting. If necessary, in order to secure priority of discovery or invention, the results may at once be published, by communication to such recognised national, scientific or photographic society, as the Research Grant Sub-Committee may decide.

There are two important points here to which special attention should be drawn. First, there is no restriction as to the status of applicant. Obviously he may or may not be a member, free to all, and every application would be considered on merits.

The second point is also the second condition, which deals with the purchase of permanent apparatus. This we know has no misapprehension, and it has been stated that it acts as a deterrent. It is a wise condition, but the Research Grant Sub-Committee has power to abrogate even this.

One may possibly be speaking *ultra vires*, but we believe we are not when we state that the Council of the Convention would not assist anyone by a grant, and would read the conditions generally as possible if they were assured that the application was genuine and likely to lead to good work. There are many things which want clearing up in connection with photographic technique, and we hope that before twelve months have passed we may be able to record one, if not more, grants in aid of research.

We are aware that we called attention to this point last year, and have long since learnt that it is only constant reiteration which fixes the attention.

The prospects for this year's meeting, with all due reservation as to the weather, are good, and we look forward to a successful meeting as in the past. It is not our duty to canvass for a meeting for next year's meeting; but, as the council have unanimously decided to advise Brussels, we trust the members at the next general meeting will adopt the suggestion. It is not the powers of the Convention to meet outside the United Kingdom, for the only rule bearing on the subject states that members of the Convention shall assemble annually in a place to be fixed upon at the previous general meeting." Brussels has the charm of perfect novelty to the majority of members.

It is as easy and cheaper to reach than many places in the United Kingdom, and, speaking from personal experience of those who have sent the invitation, we feel sure that they would find that it is possible to give us from this side a most hearty welcome, and ensure our having a good time.

There is yet one point to which we may draw attention, and that is the honorary secretary's invitation to professional photographers to meet and discuss matters concerning them and their business. We hope that many will take advantage of the opportunity, for such discussion can but lead directly or indirectly to permanent good. Many professional photographers make the convention week an opportunity for a brief holiday, but more will be welcome, and we should like to see it made an integral fixture of the Professional Photographers' Association.

#### CONVENTIONALITIES.

C. U. K.—Who said that P stands for the word picnic? And does, why not? I for one, as an old Conventioneer, do not venture to complain about the arrangements. There is all the rest of the year to struggle with the "old bread-winner" at home, and the least that an old friend from Dalston can do for my five shillings is to give me a rest from it when I try to get a week's holiday. Oh, yes, that's the real BRAIN'S SERVICE that photographers want, either more or less of it, and, thank heaven—I should say thank Bridge—no one need have more photography than he wants at the Convention.

No, photography at Hereford, as at previous centres which the Convention has condescended to visit, may be expected to be at a discount, although there will be some opportunities in the evenings after the day's work is done. But attendance is not compulsory, and for this relief much thanks. A July evening in so charming a place as Hereford can be well employed out of doors. But Big Guns will let themselves off nevertheless, and one of them will be welcomed by conventioners in the person of the past president, Mr. E. J. Humphery, who is going to tell us about his most recent invention, "A new aid to pictorial photography." Ye gods and pretty goddesses who flit about Bloomsbury! Is he about to relinquish platinum and go in for GUM?

I shall certainly go to hear that paper, and also another, to be delivered at the same time and place by my learned young friend, Dr. Mees. Of course, when I write of Mees as my friend I only use the word in a conventional sense; as a photographer he is no friend of mine, or of photography. What connection can there be between gamma and development, I should like to know? Fie, fie upon you, young man, you are mistaken.

The lowering of photography from the heights of an impossible art to the depths of a practical science is mean. To write theses about it and make it a stepping-stone to a doctorate may be said to be mean to a degree, but to collect the writings and publish them in book form at 6s. 6d. is an insult to the "Times" Book Club. I think Dr. Mees should have been satisfied to be able to say, "What I have wrtten I have wrtten"; but some people are never satisfied. At least, I'm not.

I am told that all the arrangements and the programme of our proposed doings at Hereford have been very carefully schemed; in fact, that the entire programme of the Convention will be carried out to the tick of the clock—as a matter of fact, of the Watkins' clock. In language to be comprehended by common people, it is arranged that, precisely at 2.30 p.m. on Monday, July 15, President Watkins, J.P., now happily recovered from his recent accident (those beastly motors again), will start the centre second hand of the 1907 dark-room Convention clock, set the factorial calculator, and, having allowed thirty minutes for the full appearance of the images of good conventioners, and also of that of His Worship the Mayor of Hereford, will thereupon proceed to complete development by delivering his presidential address to the great edification of all concerned. Subsequently there will be a swarty and musical promenade, and, inadvertently, refreshments. Under similar circumstances I believe that Mr. Samuel Weiler would have expressed his opinion that the notion is "werry good."

I like refreshments myself, which reminds me that there is a Convention dinner on the Wednesday evening. Now I come to look at the programme, Wednesday is a regular beanfeast, the president giving an "At Home" in the afternoon and more refreshments. But about the dinner and the speeches. I do not know what time the hotels close at Hereford, but whatever time that may be, if it could but be arranged to have the speeches first we'd never get to the soup. Possibly conventioners might get a peck at the hors d'œuvres, and, in an absent-minded manner, might munch a bit of their dinner roll; but the dinner, as a dinner, as a meal, wouldn't come off. "Come off!"—the words ought to be emblazoned like a text on the wall of the dining-room in the largest of large letters. I hope the president will keep his eye on the 1907 dark-room convention clock this year. But there! The speeches don't come first, the dinner does—and "Time, gentlemen; time, time, please!"

Talking of closing time reminds me that at earlier conventions a few of us have had some of the best fun after "closing time," at convivial gatherings, when the cock and hen brigade were gone to bed! I had supposed those times altogether past, but that I have been told a tale about an editor (whom I hope to see at Hereford this very year) who was so desirous of joining a party of choice spirits engaged in a post-conventional séance at the Southampton meeting that he elected to climb in through the coffee-room windows, admission by the front door being denied by the hotel Cerberus. This

no doubt is but a scandalous tale. At any rate, tales are told at Convention gatherings, and, if you doubt me, ask my Shakespearean friend, Baldwin, who is an authority on tales. I would like to ask you whether you have heard the tale of the man who—but, on second thoughts, wait till we meet at Hereford.

\* \* \* \* \*

Note.—“A meeting of professional photographers will be held in the Committee room from 7 to 8 o'clock.” My dear Bridge, this statement is so positive and so sudden. Really, in the present state

of bad trade and high rates you hardly expect professional graphers to attend the Convention, at least not real professors why, they can hardly afford to support their own association P.P.A., which works hard for them. But I have not forgotten “the object of the Convention shall be the advancement of graphy and of the interests of photographers,” and double little attention on your part is only preliminary to handing over of your substantial cash balance to the funds of the Professional Photographers' Association. Won't it be nice?

## FIRELIGHT AND LAMPLIGHT EFFECTS BY DAYLIGHT.

[The two following methods by which extremely novel and pleasing effects are obtained entirely by daylight have been worked out by one of the younger members of the profession, Mr. Henry Essenhigh Corke, of Sevenoaks, in whose hands they have proved of considerable value—from a monetary as well as from a pictorial point of view. The lamplight effects are the outcome of Mr. Corke's earlier work in working out a daylight method of making firelight effects. An example of the final result aimed at in each kind of portrait is presented in the supplement plate contained in this issue.—Eds “B.J.”]

THE idea of firelight portraits is, of course, by no means new, but, to the best of my knowledge, has not yet been generally used commercially by the profession, although they seem to have had a decided fascination for amateurs.

The great objection to the usual method of producing the effect is the inconvenience, not to mention the danger, of using some form of flash powder, also the results of all such studies that I have seen are pictorially spoiled by the very harsh shadows and forced detailless high-lights even supposing that the usual great flame coming from the fireplace is avoided by using a sheet of glass.

It must be remembered, too, that most people want to look at least their best in a portrait, and to achieve this it is imperative that the effect of lighting be capable of being carefully studied and arranged. As this calls for a steady and constant light the use of flash powders is impossible.

Keeping this fact in mind I began about a year ago to try to discover a reliable means of obtaining the firelight effect without the aid of a flash powder, and not having electric light had to employ the only other means and the one that cannot yet be surpassed, “Daylight.” The accompanying illustration of my studio will explain at a glance the arrangement of the sitter and lighting, which, as will be seen, is extremely simple.

The entire studio should be kept darkened as much as possible by having all the blinds closed, with the exception of about one square foot of light, which should be immediately in front of and on a level with the sitter's feet. To do this it will be found necessary in most studios, I presume, to raise the sitter to the level of the side windows. Naturally, to obtain concentration of the lighting, the sitter should be as close to the source of light as possible, and it is advisable to use a dark background. In fact, the general idea of lighting is what is so often called “Rembrandt.”

A fender placed in front of the sitter's feet on the ground (platform) will give the keynote to the idea, the sitter then may be posed, and the lighting carefully considered and adjusted by arrangement of the blinds, etc.; until excessive shadows and awkward high-lights are modified and the exact desired effect obtained. After a few experiments the required exposure can always be given with certainty of the results on that score.

Generally speaking, it is advisable to rather under than over-expose, as the negative should be if anything on the hard side, to accentuate still more the effect aimed at. The average exposure which I find about correct, working with a due north light (through ground glass) with the sitter about two feet from the light, and using extra rapid plates with the lens stopped to about  $f/5.6$ , is  $1\frac{1}{2}$  to 2 seconds.

It may happen that some studios have very little side light

owing to the proximity of high buildings, and in this case would be necessary to adjust a large white reflector placed beside the window at an angle of 45 degrees.

After obtaining a good number of firelight effects by the method described above, the desire to vary the style and yet keep the main idea occurred to me, and next to firelight, as a novel lighting effect, lamplight and candlelight effects seem natural to follow. Accordingly I turned my attention to these, and arrived at such measure of success as shown by the supplementary illustration. The main differences from firelight are the light must strike downwards, and that the actual (supposed) source of light must appear in the prints. Thus, where firelights the fire itself need only be suggested by the effect, yet in lamplights the actual lamp itself must show, and, moreover, it must show properly, as it will be almost, if not quite as important as the sitter.

To obtain a successful result was by no means easy, and a deal of time, thought, and patience, and many spoilt plates expended before a suitable and reliable method could be worked out.

The main point to consider was the lamp itself, and for this purpose I obtained a table lamp with a pink silk shade. This gave me the advantage of avoiding the actual naked flame, although with great care a naked flame can be successfully imitated. I next carefully studied the effect of light and shadow upon the lighted lamp in a dark room, the lamp being the

EXAMPLES OF FIRELIGHT AND LAMPLIGHT EFFECTS BY DAYLIGHT ONLY.

By HENRY ESSENHIGH CORKE.

*An article describing the methods employed for producing the above effects appears in the literary pages.*

in the room, because, of course, if an actual lamp was in the picture, and the lighting (daylight) allowed to upon it as it would upon the sitter, the daylight would be much stronger and actinic than the lamp, that the relief upon lamp would make one side light and the other darker, in fact, the whole thing would look merely what it was, would not in any way suggest that the sitter was photographed by the light of the lamp.

It then occurred to me that the lamp must have a perfectly flat surface, just in the same way that a background is a flat surface. For this purpose I photographed the lamp in a dark room, removing the glass chimney. I suspended a piece of mesium ribbon upon a wire inside the shade so that it hung in the place of the wick. After a few failures from one exposure and another I obtained the negative, a print of which is reproduced.

The next step was to make an enlargement from this negative of the exact size of the actual lamp (25 inches), mount it upon stout card and carefully cut out all round the outline. A support back was then fixed to it so that it would stand perpendicular, and then I had a "dummy" lamp, which, photographed again, would give the exact appearance as regards lighting and perspective of a really lighted lamp. Thus by substituting the dummy lamp one has only to arrange the lighting of the subject so that the light appears to shine from it on to the background and surroundings.

In firelight, the room must be kept darkened, and only a small area of light used to give the effect, also the sitter must be placed so to the light to give concentration of lighting.

It is necessary, therefore, to have a very complete set of side-lights, or, better still, to have a screen similar to the one described in a recent issue of "B.J." by Mr. Hewitt, which

forms quite a little studio by itself so far as blinds and lighting arrangements are concerned.

The screen I made for this purpose is 10 feet high and 12 feet wide, and has a complete set of thirteen terra-cotta saten blinds, and also a long butter muslin blind on the back, which diffuses the light when it is used.

It will be observed from this that an almost infinite amount of exact adjustment is obtainable.

The lighting must be very carefully arranged so that the effect is that of strong light coming from the lamp on to the sitter, and graduating into darker tones on the parts of the drapery and surroundings which fall outside the actual rays of light from the lamp. This is arranged so that in reality the light comes from a source on the left-hand side (in my illustration) of the lamp, and passes past it and parallel to it on to the sitter.

The "lamp" being so thin (eight or ten sheet cardboard) does not throw any perceptible shadow.

At the same time a certain amount of light must fall directly on to the flat surface of the "lamp" in order to give an exposure sufficient to obtain the details of it, and this I find is best accomplished by reflecting a certain amount of light back to the lamp from a mirror upon the shadow side.

The greatest difficulty arises in so arranging the lighting that it looks correct, yet is at the same time just the right strength upon both the sitter and the lamp to give each a correct exposure on the same plate. However, a few spoilt plates and a little time and patience will soon enable one to gauge this, and a great

deal can be put right by careful shading, sunning down, and printing up when the prints are made.

For lamplight effects it is better and more natural to retain almost all the shadow detail, and not, as in firelight effects, regard only the high-lights and half-tones. It is therefore advisable to give a full exposure and develop very carefully.

The exposure of the illustration was about six seconds, working at 6.30 p.m. in very dull and rainy June weather, and with the lens at  $f/6.5$  on an extra rapid plate. On a fine day, from 11 till 3, about  $1\frac{1}{2}$  to 3 seconds would be ample.

The accompanying illustration must be regarded more as an experiment than as a pictorial success, as many details, and more especially the pose of the model, darkness of the pedestal, unsuitable background, etc., might be more carefully attended to and avoided. Also, the strut of the lamp should have been hidden by the lamp itself.

The prints are preferably made in carbon upon an orange transfer paper, but if the carbon process is not required then

any other process may be employed, such as P.O.P., or gaslight.

After the final washing the prints should be blotted while still "tacky" are stained to an orange colour by any of the transparent colours now upon the market are used extensively for the cheap colouring of posters. They may either be plunged into a bath of the colour, or only a few prints are to be treated, the dye may be applied with a sponge or tuft of cotton-wool.

My first experiments of staining the prints were made with a solution of eosine and methyl-orange, but as these to be fugitive I tried the Vanguard Co.'s "Bertha Orange." Nothing could be more simple or effective than the use of this colour for the firelight effect.

Should "Bertha Orange" be too yellow it may have a trace of "Bertha Garnet" added to give it a more tinge. The strength of the solution of dye does not matter, as if it is too weak in colour a stronger solution may be used as a second coating, and if it is first applied too thickly the picture may be rinsed under the tap until the surplus is removed. The prints must not be washed after staining. They should be either mounted at once or laid out to dry. Preferably they should be dry-mounted or stuck only round the edges with dextrine paste, otherwise while damp the stain will come off everything with which it comes into contact, with the result that unless care is observed the next batch of mounted prints may be spoiled by the stains.

It is advisable to retain special mountant, blotting paper, etc., and a special bench for stained prints, quite apart from the usual outfit.

Such dark pictures as these must not be mounted upon ordinary mounts. Generally speaking, a dark brown will suit this style to perfection. In the case of enlargements or large prints, if framed, a deep stained oak moulding, without a gilt border and framed close up, will be effective.

It is difficult to state what should be a fair and reasonable price to ask for this style, depending as it does upon the charges of each individual worker, but as the arrangement of the sitter and lighting, and the extra care and trouble which will be necessary at the time of sitting, combined with the novelty of the results, will make an impression upon the public, a higher fee than for ordinary work should be easily obtained. As an attractive window or show-case display a few of these studies will be found to cause considerable comment.

In conclusion, I would strongly suggest that no proofs of subjects should be submitted *unstained*, as the effect is spoiled if the prints are only in black and white.

HENRY ESSENHIGH CO.

## STAND DEVELOPMENT WITH PYROGALLOL.

[Gradually we are all coming round to the idea that examination of a plate during development or tinkering with the solution is of little value. Mr. Harris's article is, therefore, timely, and well worth careful consideration. Two negatives developed by his method have been sent us, and they are perfect technically, presenting no appearance of pyro stain, but the peculiar greenish image so characteristic of pyro and so much admired by some workers.—Eds. "B.J."]

PHOTOGRAPHY, now, is of a sufficient age to permit of many of its earlier processes being re-invented, without their lack of originality being discovered by a generation little given to the historical aspect of the science it professes. Scarcely a week passes that does not see formulæ given and accepted as a new departure which might be found already described in earlier photographic papers. Unfortunately, these formulæ are usually associated with their latest advocates' names, and henceforth the original author is entirely ignored. Too much credit cannot be given to those authors who conscientiously look up

their references when writing on any subject, and duly cite chapter and verse, a practice gratifyingly on the increase.

### Stand Development of the Eighties.

Stand development is one of the processes re-invented for the admiration and use of a later generation without any reference so far as I can find, to its original introducers, Wratten and Wainwright, who described it about 1882 for use with ammonia. Such a method would, of course, at the present time meet with the immediate condemnation of the horrid developers, but it was an eminently workable process, and

very satisfactory results. It was in daily use twenty-five years ago by several large commercial firms, who produced negatives of great excellence and uniformity by it. I, myself, saw it used in the workrooms of Mr. J. Hudson, the photographic publisher, who used it exclusively for all sizes up to 10, and I have known as many as twelve dozen 12 x 10 sized negatives made and developed in one day by two persons using stand development with pyro-ammonia, on the suggestion by Wratten and Wainwright. Of course, as has been said, such a method of work should, according to the day teaching, have been wholly impossible, but the negative yielded could not be surpassed for quality at the present time.

Usually three dipping baths were employed by each worker, and the solution made up in the morning was employed throughout the day, being strengthened when half the day's work was done by the addition of dry pyrogallol and ammonia. The method will naturally suggest itself as to the colour of the negatives, more especially when it is said that no "pyro-pretive" was used. A bath of alum and citric acid was employed between development and fixation, which bath was used as often as necessary, i.e., when it failed to sufficiently remove any stain. The appearance of the developing solution at the end of the day can only be conveyed by comparing it with the familiar "Guinness," yet the negatives had no objectionable amount of colour when finished.

Ten years ago I had several hundred stereoscopic negatives to develop, which it was necessary to accomplish expeditiously, so I decided to adopt Wratten and Wainwright's method of dipping-bath development, using (instead of pyro-ammonia) amidol, which the makers of the plate (a foreign firm) recommended in preference to any other reducer. I was particularly charmed with the facile way in which the plates developed with the fine quality of the negatives. I used three baths, the whole batch was developed easily in one day. This method I mention because, quite lately, I saw a statement to the effect that amidol was not suitable for stand development. It may be that the plates were especially suitable for development by amidol, for I have known plates that would give their best results when amidol was used.

#### A Pyro-soda Formula.

My interest in stand development was re-awakened last autumn on returning from a photographic tour with a large number of negatives to develop, and limited time in which to do so. I decided upon stand development with pyro-soda as the most convenient and expeditious. The exposures and subjects presented a pleasing variety, from one-hundredth of a second to several minutes on landscape and architectural subjects of every description. Three dipping baths were used, each containing forty ounces. The formula was:—

Pyrogallol .....	20 grains.
Sodium sulphite .....	120 grains.
Potassium metabisulphite .....	30 grains.
Sodium carbonate .....	240 grains.
Water .....	40 ounces.

A bath composed as above the plates developed with great clarity and steadiness, and exhibited that charm of stand development, no sign of the fully exposed plates "rushing up" and losing their scale of gradation.

#### Strengthening the Bath.

While the bath was fresh the developed plates were transferred, after rinsing, to an acid fixing bath, and the colour of the negative was of a neutral grey without any sign of yellowing; but as the bath became more oxidised some colour began to manifest itself, so the plates, after development, were placed some minutes in a 1 per cent. bath of sodium bisulphite. When the baths commence to show signs of working slow, which usually happens after several dozen plates have been developed,

I find it advisable to renew them by the addition of sulpho-pyrogallol and carbonate; in fact, I allow half a grain of pyrogallol (plus its preservative) and six grains of carbonate to each half-plate, so that when some three dozen half-plates, or an equivalent of whole plates, have been passed through the bath, I add stock solution accordingly. This probably is rather a rule of thumb method, but it answers very well in practice.

Later on, having a large number of reproduced negatives to make, I gave this method of development a lengthy trial, and found it infinitely more expeditious and convenient than developing in a dish. The strength of the formula given above may, for reproduction work, be advantageously doubled, as the exposures can be adjusted to suit the quicker working bath. The plates used in making these reproduced negatives were of my own preparation, with a speed of about 100 H. and D., and gave density very readily, so, by keeping three dipping baths in operation, I was able to get over a large amount of work very quickly.

The length of time occupied in developing each plate with bath development and the formula given varies somewhat with the make of plate, and is of course largely influenced by the amount of working the bath is subjected to without strengthening. Using plates of my own preparation I find the time for each plate averages pretty constantly five minutes at about 60 deg. F., and when this time is exceeded to any extent I take it as a hint that the bath needs replenishing by the addition of stock solution. Though I have little experience to speak from, I expect that most commercial plates will require rather longer than this.

If uniformity in working is desired, attention must be paid to securing constant temperature, and I find it necessary in winter to use a bath capable of holding the dipping baths and a sufficiency of water at a temperature of 60 deg. F.

Now for years I had exclusively used tray development for all negative work, employing principally pyro-soda, but when I compare some nine months' work with bath development with my previous long spell of dish development, I find the balance of merit to be altogether with the bath. Of course, where only a few plates are in question it will hardly be desirable to make up the quantity of developer necessary for the bath, but a photographer usually has sufficient developing in hand to warrant at least the use of one bath. One great recommendation bath development has is the ease with which the plate can be left if any other work requires momentary attention; there is no need to mount guard over it; a much pleasanter light may be used in the dark room; the baths may be covered up and white light used in the room at any moment; and the fingers are kept free from stain.

It will probably surprise many using bath development for the first time with pyrogallol to find that even when the solution has become quite deep-coloured plates can still be developed free from stain therein. A good deal depends on the plate itself, the plates of one maker will develop quite free from colour in a bath that will cause considerable stain with plates of another make. By using the acid sulphite bath between development and fixation it is not at all difficult to secure freedom from stain, care being taken to replace it with fresh solution when it becomes neutralised and discoloured.

#### Freshly Made Pyro Solution.

One great factor in securing freedom from stain when using pyrogallol is the condition of the pyrogallol itself. Some time ago the Editor of this paper drew attention to the staining proclivities of stock solutions of pyrogallol, and there is no question in my mind as to the correctness of his views. I have experimented very largely with pyro preservatives in the past, and long ago came to the conclusion that to secure freedom from stain it was necessary to use the pyrogallol developer freshly prepared. It may be convenient for the worker whose develop-

ing is intermittent to have a stock solution at hand, but for the daily worker the trouble of making up his developer before commencing work is so small, and occupies such a few moments, that he can well afford to consider himself independent of the vagaries and unreliability of stock pyrogallol solutions. Looked at with the light of later experience there is no doubt that a good deal of the success of the early workers with stand development was due to their method of preparing their baths with fresh, dry pyrogallol.

It may be urged that as long as there are non-staining

developers to hand why not employ them for stand development and leave pyrogallol alone? I seriously question whether it is one of the more recently introduced reducing agents that all-round efficiency and moderation in cost, has any advantage whatever to offer over pyrogallol as a developer for plate suits every make of plate, which is more than can be said of several of the new reducers, and it has so firmly established itself in the photographer's favour that with its possession well claim its proverbial nine-tenths.

G. T. HARRIS, F.R.E.

## DR. SIEGFRIED CZAPSKI.

PROFESSOR DR. SIEGFRIED CZAPSKI, whose death with great regret we briefly announced last week, had been in some-  
what indifferent health for some time. He died suddenly on June 29 from hæmorrhage of the lungs. Professor Czapski was born on May 28, 1861, at Odra, in Posen, and received his education at the Maria-Magdalenen - Gymnasium at Breslau. In 1879 he entered the University at Göttingen, where he commenced his studies in physics, mathematics, and chemistry, which were continued at Breslau. Amongst the celebrated professors under whom he studied were Helmholtz, Kirchhoff, and Kummer. In 1884 the degree of Doctor was conferred on him for work on the thermal variability of the electromotive power of the galvanic battery.

An important step in Dr. Czapski's life occurred shortly afterwards, when Professor Abbe invited him to come to Jena, where he commenced his valuable work in connection with the Carl Zeiss optical institute. Subsequently he was chosen as assistant to Professor Abbe and greatly helped him in carrying out his great industrial and social reforms in that great scientific institute.

It is now universally recognised how nobly and unselfishly Professor Abbe used his position in the firm of Carl Zeiss, first as scientific adviser, then as partner, and finally as sole proprietor, to bring about the well-known reforms in the business and social position of the employees, which culminated in the founding of the "Carl Zeiss Stiftung," which brought employer and employees into the present common interest relations. In this great undertaking Czapski worked side by side with Abbe.

In 1893, Dr. Czapski was appointed a director of the firm of Carl Zeiss jointly with Professor Abbe and Dr. Schott, and in

1902 he succeeded Abbe at the head of the Carl Zeiss Stiftung. That he worthily followed in the footsteps of his great

THE LATE PROFESSOR DR. SIEGFRIED CZAPSKI.

decessor (and not in the social side), amply testified by colleagues, the scientific staff and workmen of the Carl Zeiss Institut at the funeral ceremony. Dr. Czapski was a zealous and warm supporter of the Debating Society, the Technical School at Jena, the German Society of Mechanics and Optics, the German Museum, the Meisterwerke der Naturwissenschaft, Technik, and also curator of the Kaiser Friedrich-Gedenkmuseum in Jena. He aided largely in the conduct of the Zeitschrift für Instrumentenkunde. In recognition of his services in so many fields, the Prussian Government conferred upon him by the Minister.

Since his entry into the Zeiss Works, Dr. Czapski's publications were confined to optical subjects. Sometimes they were communication novelties in optical instruments and other theoretical researches. The former frequently

dealt with new instruments or improvements in existing devices devised by Professor Abbe. Of theoretical researches we need not omit to mention a treatise on the possible limits of the microscope. Dr. Czapski's greatest scientific work was undoubtedly the "Theorie der Optischen Instrumente nach Abbe," which first appeared as part of Winkelmann's "Handbuch der Physik" in 1893. This work has become extremely important in consequence of the great advance in photographic optics during the past twenty years. It had special interest to readers of our journal, and they will doubtless remember that a few years ago Dr. Czapski was elected an honorary Fellow of the Royal Photographic Society. Dr. Czapski's interests

photography was alive to the end, and his last work, which was published in the December and January issues of the "Photographische Korrespondenz," dealt with the "value of photography for scientific investigation."

It may be briefly stated that the main object of the greater

portion of Dr. Czapski's scientific publications was to popularise Professor Abbe's investigations in geometric optics.

His premature death at the early age of forty-six creates a void most difficult to fill, and his death will be deplored in scientific circles throughout the world.

## NOTES ON SULPHIDE TONING.

Sulphide toning of bromide prints is generally stated to be an extremely simple operation, but notwithstanding this there are many who fail to obtain those rich brown tones so much desired, and get instead the sickly yellow, more unpleasant than a fixed untuned P.O.P. print. I attribute their lack of success to the very inadequate directions given by paper-makers and others for working this process. Numerous inquiries addressed to manufacturers and others have generally resulted in information which has not led to a solution of the difficulty; and suggestions as to the cause of failure, when carried out, seldom gave any better result. One told me to boil the sulphide bath; another, to develop the prints exactly for two and a half minutes, and all would be well; but, unfortunately, neither of these directions was of help in my case. If one desires information on the use of development with soda or toning P.O.P. prints, the most explicit and detailed instructions are given, and I hope to supply the demand for similar directions for using the sulphide bath, for want of which as on the point of giving up this most useful process, when I was put on the right path by a hint from another experimenter on this matter, and by further investigation evolved the following essential points of success, by attention to which one cannot fail to obtain a good rich colour on any bromide print. The prints must have been absolutely dry at some time between fixing and bleaching.

The print has not dried it will bleach very slowly, and may take hours, and if parts only are still damp the final tone will be uneven, as it will also be if the hypo be not thoroughly washed out before bleaching.

The final tone is said to be affected by the brightness of the negative and by the duration and completeness of development, these statements may be ignored if the more essential points are carefully carried out.

I have taken prints from the same negative, developed one for about one and a half minutes, one for two minutes, and one for longer. I also purposely over-exposed one and developed it completely, i.e., until it appeared fairly right. I toned all three together, and got identical tones on all.

It is true that the surface of the print affects the colour at times. A glossy print tends to give yellower tones and a rough surface richer browns, but this is not always the case. Different grades of paper will, of course, sometimes differ slightly in the final result.

The composition of the "bleach" and the method of using it, next to point 1, the most important to observe. The strength of the solution does not matter; it only acts quicker or slower as it is concentrated or dilute, but the proportions of potassium ferricyanide and potassium bromide should be carefully noted.

Make up the following:—

Potassium ferricyanide .....	2 oz.
Potassium bromide.....	$\frac{1}{2}$ oz.
Water .....	48 oz.

This will keep in good condition for some weeks.

In cold weather this will be found to act fairly fast, but in

warm weather it can be diluted with once or twice the volume of water.

The amount by weight of bromide should be quarter that of the ferricyanide; less will give the same result, but will bleach slower; more tends to a yellow tone.

4. The amount required for a batch of prints should be taken and thrown away after use. On no account put it back into the stock bottle or use it for a second batch.

Mr. Blake Smith, in his book on this subject, states that the ferricyanide bromide bleach may be put back into the stock bottle and used over and over again. It may be so with ammonium bromide, which he gives, and which I have not tried, but it certainly is not so with the potassium salt.

The prints may be put in either wet or dry—that is, they may be wetted first, if attention has been given to point 1, and if they bleach unevenly through overlapping, etc., it does not matter, provided they are carried as far as they will go. They should then be washed until the yellowness has all gone.

5. The sulphide bath is usually made as follows:—10z. of sodium sulphide is dissolved in 10oz. of water, and boiled to precipitate the iron. It is then filtered, and made up to 10oz. once more. One ounce of this and 9oz. of water make the working solution, into which the bleached and washed prints are immersed, taking care this time that sulphide flows evenly over the print, or markings may result. The prints are then washed and dried.

The Editor of the "B.J." says that the used sulphide will not keep, as it is liable to stain the whites after it has been used a few times. In place of the sodium sulphide I now use ammonium sulphide, of which I pour a few drops to the pint of water. It gives identical tones with the sodium, and, being already a liquid, saves the trouble of making up.

Its disadvantages are that the smell is rather unpleasant and the fumes must be kept away from sensitive plates and paper. As it is in use for only about two minutes at a time, and then in a very dilute state, these difficulties are easily avoided.

6. The sulphide softens the gelatine, and on thin papers is liable to produce blisters, not in the bath itself, but in the final washing. They appear as in albumenised paper where there have been kinks in handling the prints. They may be avoided entirely by using an acid hardener in the hypo, and as an extra precaution in the case of thin papers a few minutes in a 10 per cent. formalin bath before the first drying. It does not appear to be necessary to wash the formalin out. If the prints are required to be glazed they should be given another formalin or alum bath after the sulphide.

The tone always appears colder on drying, but the method enumerated above does not reduce the prints at all, so it is not necessary to get a darker print to start with as generally stated.

Finally, to avoid blisters, it is advisable to keep prints flat, and when working large sizes a zinc dish should be used, which can be economically made by a tinsmith. This may be used for developing and toning, but not for the hypo bath, for which I use a wooden dish lined with wax. One in use sprang a spring to leak after six months' continual use, but a touch with the iron made it as good as new.

It is tant that

## FOREIGN NOTES AND NEWS.

### Stereoscopic Photomicrographs.

M. Monpillard, at a meeting of the Société Française last month, described a method of obtaining stereo-photomicrographs by illuminating the object first from the right and then from the left by swinging the mirror. A later improvement is the use of a half diaphragm on the condenser, which is shifted from one side to the other. This idea was utilised more than ten years ago by Mr. Iles, of Birmingham, we believe, and it gives very effective results.

### The Improvement of Bromide Prints.

M. Underberg suggests that misty bromide prints can be considerably improved by immersion in the mercuric iodide intensifier. On immersion in this the prints assume a nasty yellow tone, but if washed and immersed in a metol-hydroquinone developer, the image is converted into a fine blue-black colour. Prints thus treated have been exposed, both damp and dry, to sunlight for six weeks without showing any change of colour.

### Development in Daylight.

In the current number of the "Zeitschrift für Wissenschaftliche Photographie," M. B. Szilard recalls the fact that, excluding particular forms of apparatus, Spiro, Williams, Ludwig, Herman and Schulze, Süss, Lumière and Seyewetz and others have suggested the use of dyes in developers so that plates could be developed in daylight. It is important that the dyes should be soluble or miscible with alkalies, and also form colourless compounds with acids, or, in other words, that the gelatine should not be permanently stained. Numerous experiments have led him to finally adopt the following formula as perfectly satisfactory:—

Luteol .....	2 gms.
Phenolphthaleine .....	3 gms.
Alcohol .....	100 ccs.
Glycerine .....	50 gms.
Caustic potash .....	1.2 gms.

To every 100 ccs. of developer should be added 20-60 ccs. of the above solution, which is deep red in colour and perfectly protects the plate from any actinic light. M. Szilard states that this, if sufficient depth of developer be used, is applicable to the most rapid ordinary or orthochromatic plates, provided direct sunlight or the electric

light be avoided. The above solution forms also an efficient for tank lamps.

### A New Developer.

A German patent has been granted to Fritzsche and Co., of Hamburg, for the use of protocatechualdehyde or its bisulphite pound as a developer. The action is due to two hydroxyl groups in the ortho position, and is increased by the addition of the hyde. The presence of the latter enables the developer to be with sodium bisulphite. A typical formula is 1 part protocatechualdehyde, 5 parts sulphite, 5 parts potassium carbonate and a little potassium ferrocyanide. It is claimed for this developer that it enables over-exposure to be compensated for, and soft, monious negatives are given, even with long exposures.

### Toning Bromides.

Herr A. F. La Rin in "Photographische Kunst," calls attention to the well-known fact that different tones are obtained on bromide prints developed with different developers, and gives the following table of his results, with some of which, however, we can agree:—

Developer.	Hypo-Alum (Brown).	Iron (blue).	Uranium (red brown).	Copper (red).	Uranium (Green).
Amidol .....	Best	Not satisfactory	Whites stained	Very suitable	Very suitable
Metol - Hydro	Unsatisfactory, sometimes will not tone	Satisfactory, only slight change	Unsatisfactory	Tones less	Unsatisfactory
Hydroquinone	Same as above	Fine tone	"	Stains slightly	"
Edinol .....	Fine tone	Unsatisfactory	Good	Suitable	"
Ferrous Oxalate .....	Satisfactory	—	Fine tone	—	—
Rodinal .....	"	—	Unsatisfactory bronzing	Suitable	Suitable
Pyro Soda .....	Unsatisfactory	—	Unsatisfactory	"	—

## Patent News.

*Process patents—applications and specifications—are treated in "Photo Mechanical Notes."*

The following applications for Patents have been made between June 24 and June 29:—

**PRINTS.**—No. 14,471. Machine to facilitate the production of photographic prints. Frederick William Emuss and Montague Picton Prout, 98, Balham High Road, London.

**CINEMATOGRAHS.**—No. 14,493. Improvements in cinematograph pictures. Bessie Kate Brown and Theodore Brown, 8, Villa Road, Brixton, London.

**PRINTS.**—No. 14,505. Improvements in apparatus for drying photographic prints. B. J. Hall and Co., Ltd., and Benjamin James Hall, 39, Victoria Street, London.

**SOUVENIRS.**—No. 4,662. Device for producing photographic souvenirs. Courtney Spencer Jones, High Street, Woodford Green.

**COLOURING PHOTOGRAPHS.**—No. 14,666. Improvements in the colouring of photographs, and in the apparatus for use therein. John J. Griffin and Sons, Ltd., and Thomas Arthur Moryson, 322, High Holborn, London.

**SHUTTERS.**—No. 14,728. Improvements in camera shutter releases. Charles Chase Little, 53, Chancery Lane, London.

**CUTTERS.**—No. 14,760. Improvements in or relating to cutters for photographic prints and the like. Joseph Thacher Clarke, Chancery Lane Station Chambers, London.

**FILMS.**—No. 14,858. Improvements in films. Ozias Dodge, 7, Southampton Buildings, London.

**CAMERAS.**—No. 14,916. Improvements in photographic cameras. Herbert Holmes, William Albert Edwards, and Houghtons, 188, High Holborn, London.

**BIRD'S-EYE VIEWS.**—No. 14,932. Improvements relating to a method of, and apparatus for, photographing bird's-eye views. Paul Theuerkorn, 20, High Holborn, London.

**CAMERAS.**—No. 14,966. Improvements in cameras. John Edy Thornton, 6, Bank Street, Manchester.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**REPRODUCTION PROCESS.**—No. 11,312. A.D. 1906. This invention has reference to the obtaining of direct positive copies or similes of tracings, or translucent drawings, or other transparencies, without the intermediary of a negative, in Indian ink, carbon black, or any suitable pigment, paint, varnish, enamel, or other coloured inks or substances; or in photo-lithographic transfer or printers' inks, for the purpose of obtaining therefrom multiple copies by machine printing. Whereas gum-ferric inks are now in common use for the purpose of obtaining positive coloured copies of translucent drawings from a photo-impression, by acting on the salts of iron with certain chemical colouring reagents, such as ferro cyanide of potassium and tannic acid, or like substances, which induce only a chemically d

loped, dyed, or stained copy, quite a different property of the gum-ferric film is now proposed, which will be much more certain in its results—namely, its power of combining with some of the cyanides of potash, and of being dissolved thereby, and this invention is confined wholly to the use and application of this species of film or solution and solvents. By using them a photo-impressed gum-ferric film, and solving away the unexposed parts in a primary solving bath of preferably the ferro-cyanide of potassium, or other equivalent solvent, certain stencilling effects are produced in the film, thereby leaving the surface of the substratum in parts bare and naked, and in parts still covered by a so far insoluble film. By now treating the surface all over with insoluble pigment inks, paints, enamels, or varnishes, or with greasy printers' transfer inks, access is gained to the bared surface in the naked parts to which the ink adheres, and by using weak acids as a secondary solvent to remove the remaining film, and with it the superimposed ink, a positive mechanically developed copy of the original subject is obtained, which, being mechanically applied direct on the surface of the paper or other material, and not on a soluble surface film, is fixed hard, and cannot be removed by any solving or ordinary washing. The prepared surface is exposed in the usual way, then primarily treated with a solution of ferro-cyanide of potassium or equivalent solvent, the ferro-cyanide of potassium having, not only the effect of developing up the picture in Prussian blue, as in the blue line process, but at the same time of completely dissolving away the protecting gum ferric in the unexposed parts which are along under the lines, or the dark portions of the translucency where the light has not acted. The print may now be dried, and in this stage of the operation the surface is practically covered with a stencil film in which the parts exposed to light are still covered with the protecting film; but under and along the lines and dark portions of the transparency the raw paper is exposed and stained blue.

For producing direct photo prints or copies of the original, the surface after drying is mechanically treated all over, but particularly in these bare parts, with a prepared solution of Indian ink, pigment, paint, varnish, enamel, or carbon-black, or other colouring matter or dye stuff which will become insoluble on drying; while in the case of multiple copies to be produced by machine printing, the surface is treated with any suitable greasy litho-transfer, or printers' ink, producing thereby, and after the subsequent operation of solving away the stencil in weak acid, a transfer copy which will go down on stone or metal for machine printing purposes. The ink, colouring matter, or the like, may be applied by rolling up or with a sponge, brush, or pad of cotton wool, and will effectually stain or work itself into the surface in the open, bare, or naked parts of the stencil, where it is unprotected by the film, and which have been overshadowed by the lines or dark portions of the translucency; whereas in those other parts exposed to the action of light, on which the impermeable film still exists, the ink or colouring matter or greasy ink will be effectually prevented from reaching the surface. The copy is now immersed in a weak acid bath, which forms a secondary solvent, and which will have the effect of dissolving away the remaining film, and with it the superimposed ink, and of bleaching the copy white. A wash in water to remove the acid and the dissolved film and clean the surface is all that is required to complete the copy. Henry Lionel Shawcross, Dale Street, Liverpool.

Mr. W. F. COOPER, of Water Lane, Watford, writing to "Nature" point out the difficulties experienced by amateurs in obtaining sufficiently rapid films for the purposes of research, says the fastest he has been able to obtain have a speed of H. and D. 100, less a half that of ordinary snapshot plates. This speed is quite adequate for the photography of operations, for in a case observed Mr. Cooper an exposure of ten minutes would have been required. Cooper has been successful in recording the movements of blood puscle parasites, but the chief obstacle in the way of further progress is lack of general interest in the uses of the cinematograph by the part of scientific workers as opposed to professionals. He in correspondence with others who have taken up this line of work with the view of producing a demand for films better suited to purpose in the matter of speed and orthochromatic properties.

## Analecta.

*Extracts from our English weekly and monthly contemporaries.*

### Simplified Factorial Development.

I think beginners would take more kindly to factorial development (writes Mr. P. McGregor in "The Photographic News") if they could get it simplified, so that they could divide the number of seconds of first appearance by a factor which would give them the result at once, without having, as in the old method, to multiply by the factor and divide by sixty. My new system, which I have been using for some time, is very simple. There is no calculation required; you merely divide the number of seconds of first appearance by the factor, and you have your answer in minutes required for total development. I give some of the developing agents below, with new and old factors.

New Factor.		Old Factor.
12.	Adurol .....	5
6.	Kachin .....	10
6.	Pyrocatechine .....	10
12.	Hydroquinone .....	5
2.	Metol .....	30
6.	Ortol .....	10
10.	Imogen sulphite .....	6
5.	Diogen .....	12
3.	Edinol .....	20
12.	Pyro .....	5
Divide by 3 and multiply by 2.		Rodinal .....
		40

### Hypo Eliminators and how to use them.

The hypo eliminator I use (writes Mr. Frederick Page in "Photography") is a very dilute solution of potassium permanganate, or, if that is not at hand, Condy's fluid, which is supposed to contain sodium permanganate, will do just as well. After the plate or the print has been washed under the tap or in three or four changes of water for about a couple of minutes, it is placed in water just tinged pink with the permanganate. The pink colour will be discharged almost at once, and the solution is then changed for fresh. It is changed from time to time until the print may be left for three minutes in the pink liquid without altering its colour, and when this is the case it may be assumed that the hypo is completely destroyed. With a negative which is wanted in a hurry, but still is wanted properly washed, this process seems excellent, and has been in use for years without any failure. Now and again the permanganate will leave a slight brown stain on the negative; but a bath of five grains of oxalic acid to one ounce of water removes these very quickly, and a short wash completes the cure. But such stains are not at all common, and can be prevented altogether by washing the negative or the print as much as possible before resorting to the permanganate, and by taking care not to use this too strong.

### Judges at Exhibitions.

With reference to ideal judges in pictorial photography, a writer in "The Amateur Photographer" says: "History shows us that the men who laughed at Turner, scoffed at Monet, sneered at Whistler, and howled down Rossetti, were the leading contemporary painters. If artist-painters showed themselves such poor critics of their own art, are they to be trusted as judges of pictorial photography—an art which few of them understand, and many of them profess to despise? I do not think so. And I doubt whether men who have the artistic temperament to become first-class pictorial photographers have a temperament which will qualify them to act as clear-sighted judges. Having eliminated these, there still remains that class of men who have cultivated their critical and appreciative talents, I mean art critics of the class to which Mr. Bernard Shaw belongs. And, taking Mr. Shaw as an example, and leaving his diatribes and fireworks out of the question, I have never met with such a calm, just, unerring critic of pictorial photography as Mr. Shaw has proved himself to be. If Mr. Shaw, and several such as he, acted as hanging committee at the Royal Academy, and jury of admission at the Photographic Salon, art would be the gainer."

### The Reflex Camera.

Probably the best method of holding the camera (writes Mr. A. Lockett in "Focus") is to suspend it from the neck by a strap, with the back resting against the body. Only a slight steadying pressure of the hands is then required, and the latter are left at liberty to manipulate the focussing screw and exposure lever. It is best to have these two movements on opposite sides. When they are both on the same side the exposure cannot be given quite the exact instant that

the subject is focussed. It is advisable to have an additional focussing screen to fit the back. The apparatus can then be used on a stand at any height if desired; most reflex cameras are so provided. If, however, the camera has a screw bush at the side, it can be fastened to the tripod on that side, and the focussing done through the reflex finder. The best apparatus of this kind is fitted with a revolving back, which can readily be turned for either upright or horizontal pictures, without removing it—obviously a great convenience.

## New Books.

"The Poetry of Architecture." By John Ruskin. Pp. 276. 6 x 3. London: George Routledge and Sons, Ltd. 1s.

A well-known writer on every photographic topic, from art to chemistry, once delivered himself of an obiter dictum to the effect that no architectural photograph could be pictorial. This may be true, but as early as 1837 Ruskin had discovered that there was at least poetry in architecture, and from November of that year to December of 1838, a series of articles by him appeared in the "Architectural Review." A costly reprint appeared in 1893, but now by the issue of this edition the said articles are placed within the reach of all, and a careful study of them will, we think, teach many a photographic worker, not only that there is beauty in architecture generally, but also in detail.

Reproductions of the original woodcuts are given, because, as the editor, Mr. F. C. Tilney, says, "They evidently passed the censorship of the author, whose need of them as diagrams has led to their unhesitating inclusion here." The book is further embellished by full-page half-tone reproductions and a three-colour frontispiece, the inclusion of these being explained by the editor in the following lines: "In the case of photographs of the very places that are exhaustively treated by the author, the case is different; for the physical features, the architectural characteristics, the phenomena of light, of air, and of distance, the water surface and reflections, as well as other qualities impossible in an outline sketch, are inherent in a good photograph. It is therefore with much gratification that the editor has been able to avail himself of the excellent photographs of Mr. R. Child Bayley, F.R.P.S. (Editor of "Photography," and author of "The Complete Photographer"). These camera pictures confirm, in a remarkable way, the searching observations of Ruskin upon natural effects in those sections of the work which deal with Lakes Como and Lecco. Ruskin himself took a keen interest in photography, and such a use of it as the present could scarcely fail to give him pleasure were he alive to witness it. Further, could he have known that photographic processes would have made it possible to reproduce a Turner drawing in its actual colour, he would doubtless have eagerly availed himself of the first opportunity of pressing them into his service. No apology is needed, therefore, for the coloured frontispiece of this edition, which reproduces the Lake of Como—his favourite drawing—in Group XI. All his remarks as to the hues, the reflections, the white villas, the snowy peaks of the Larian Lake, are borne out by Turner's exquisite vignette."

We welcome this reprint most heartily, and congratulate the editor, his photographic illustrator, and the publishers on the results obtained, and we commend a careful study of this and the other Ruskin reprints in this low-priced series, to the careful perusal of photographers.

"The Year Book of Photography." Edited by F. J. Mortimer, F.R.P.S. Pp. 614. 7½ x 4½. "The Photographic News," London. 1s. paper. Cloth, 1s. 6d.

The literary portion of this work is divided into five sections, dealing with "Seascape and Yacht Photography," by the Editor; "Landscape Photography," by J. C. Warburg; "Practical Portrait Photography," by C. H. Hewitt; "Architectural Photography," by H. W. Bennett; and "Flower Photography," by Edward Seymour. There is thus considerable choice for the reader, and the information given is by no means too solid, but of the light character which will especially appeal to the amateur reader, and illustrations lend point to the stories that each writer has to tell. It is invidious to pick out any article as the best, but one may possibly think that those by Messrs. Hewitt and Bennett are the most practical, the former because it deals essentially with portraiture in a room and not a studio, and therefore being all the more valuable to the amateur

worker. Mr. Bennett's article is welcome because, whilst thoroughly practical, it lays stress on the fact that the architect-worker must be in sympathy with the work—a "sympathy amounting to reverence," as the author says.

The usual collection of formulæ and tables and novelty section appear, with complete lists of societies, trade names, etc. The forty-eighth volume of the "Year Book," and it is quite up to standard of its predecessors, and will form, as in the past, a useful reference work for amateur workers.

"Telephotography Simplified." By Captain Owen Wheeler. Pp. 8½ x 5. R. and T. Beck, Ltd. 3d.

This little pamphlet deals with the use and advantages of the lens for telephoto work, as described in our issue for May 10, p. Captain Wheeler's notes are practical, and with the illustrations thoroughly convincing as to the advantages of this hood, which now made by Messrs. Beck.

"Monographie du Diamidophénol en Liqueur Acide." By G. Balagny. Pp. 84. 7½ x 5. Paris: Gauthier-Villars. 2fr. 75c.

"Applications de la Photographie aux levés Topographiques." Henri and Joseph Vallot. Pp. 237. 7½ x 5. Paris: Gauthier-Villars. 4fr.

M. Balagny's little work is an elaboration of his method of developing with an acid solution of amidol, which was abstracted in issue for April 26, 1907, p. 308. There is, however, rather more to this in the work, and it may be taken as the best monograph on use of amidol that has yet appeared.

M.M. Vallot's work is of a somewhat more scientific interest than the above, and it deals with what we in England should call photogrammetry, or surveying by photography. The application of photography to this particular work has been much more neglected here than in France, where doubtless it owed much of that attention bestowed on it to the work of Colonel Laussedat, whose death we have only recently had to chronicle. The work deals very thoroughly with the theoretical side and the necessary apparatus, and will doubtless take its place as one of the classics on a subject which appeals to the few and not to the many.

NEW CINEMATOGRAPH FILMS.—The Charles Urban Trading Company, Ltd., of 48, Rupert Street, London, W., are placing a number of new films on the market, some of which appear to be of considerable historical and scientific interest, notably "Visit of the Color Premiers to Portsmouth," "British State Ceremonies," "The L. Shamrock," and "Through the Microscope." Several of these films should prove valuable also as "records," and as such will be welcomed by all who desire the preservation, in picture form, of unique events.

NEW EDINBURGH PHOTOGRAPHIC ASSOCIATION.—At a large meeting of Edinburgh photographers held last week it was resolved to start a new photographic association. Rules and regulations were drawn up, office-bearers and council elected, and it was agreed to open a session in October. The name of the new association is to be the Mid-Lothian Photo. Association.

TOURIST LITERATURE.—From the Health Resorts Development Association, 29, John Street, Bedford Row, W.C., we have received copies of booklets published by them for the town councils of F. mouth, Harwich and Skegness. These little guide books give much useful information, together with a number of illustrations of various districts dealt with, and those of our readers who anticipate being in the neighbourhood during the summer months would do well to secure a copy, which may be had post free on application by letter or postcard to the respective town clerks.

SHEFFIELD PHOTOGRAPHIC SOCIETY.—The annual report shows that the society is in a prosperous condition with a considerably increased membership. There have been twenty-two meetings held during the year, which have been well attended. Several well-known photographic workers have lectured before the society, and the large attendances at such lectures lead the council to believe that the policy of interchanging lecturers with other societies is appreciated. photographic workroom, which can also be used as a studio, has been acquired for the use of members, and fitted up with conveniences for developing, enlarging and reducing. A series of elementary demonstrations will be held in it at an early date. The secretary of the society is Mr. James W. Wright, 62, Vale Road, Sheffield.

## New Apparatus, &c.

The "Mite" Pocket Folding Camera. Sold by A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, E.C.

This camera is well named, as it is extremely small, and really a pocket camera, measuring, in the quarter-plate single extension,  $\frac{3}{4}$  by  $4\frac{1}{4}$  by  $1\frac{1}{4}$ , the weight being only 20oz. It is fitted with an aluminium baseboard, with rack and pinion and infinity catch. The lens is cut with a diagonal screw, and the head bears a coarse-cut ratchet, which enables it to interlock with the baseboard when pushed in, thus fixing the extension at any given point. The

utter is automatic, with various speeds, and is fitted with the best form of Antinous release. The lens is a rapid aplanat working at  $f/7.5$ . A brilliant finder, with level attached, which can be used for both horizontal and vertical pictures, is fitted to the lens front, which has rising and cross movement, actuated by rack and pinion. The whole camera is exceptionally well made, is covered with fine grain Morocco leather, and forms an excessively dainty and compact outfit. The camera is made in quarter-plate, with single and double extension, and also postcard size, the prices being respectively 65s., 80s., and 75s.

The Jupiter Electric Effect Lamps. Sold by the Jupiter Light Studio, 72, Victoria Street, Westminster.

The increasing use of electric light as the illuminant for portraiture is due not only to the variability of daylight and the greater faintness of the former, but also to the ever-increasing facility with which the current is obtainable. This new lamp is made in two forms, the one essentially a studio lamp on iron standard, and the other a portable "effect" lamp.

The studio lamp consists of a small umbrella reflector, fitted with a ring of incandescent lights, used for focussing and judging the

direction of lighting. In the centre is a special form of arc, the effect rays of which are shielded from the sitter. This arc is practically a central carbon, with an opposite pole at either end, the carbons being cored, and impregnated so as to give an intense

bluish-white light. The exposure is made with a flash lasting about 1.40th of a second, or for large groups a continuous arc can be formed. We have had the opportunity of practically testing the efficiency of the flash arc, and find that it gives fully-exposed plates. The lamp can be raised or lowered or shifted at will, and a special resistance is provided with the outfit so that it can be used with alternating or continuous current of 100 or 200 volts. The price of this is £40 complete. The "effect" lamp is, as will be seen from the accompanying illustration, a small portable arc lamp, which can be attached to any plug where electric light is available. It lends itself admirably to some charming and unique effects, and, being sent out with resistance and all complete, it can be readily used by amateurs, as well as professionals, thus opening up another amusing and useful field of work for amateurs. The price of this is £5.

### CATALOGUES AND TRADE NOTICES.

MESSRS. REYNOLD AND BRANSON, LTD., of Leeds, have sent us a descriptive price list of their sequential developing baths, the main feature of which is that each plate is placed in a separate bath, and the whole then inserted in an outer case, which can be made light-tight. Now that development in total darkness is so much to the fore with panchromatic plates, this should be of special interest.

MESSRS. ENTWISTLE, THORPE, AND CO., photo-engravers, photographers, etc., of 42, Deansgate, Manchester, send us a dainty illustrated booklet, showing half-tone examples of the class of work produced by their firm. Their studios are fitted with every facility for photographing or sketching objects to be reproduced, and members of the staff are sent to any part of the country for the convenience of customers. Full particulars, price list, etc., may be obtained from the firm at the above address, and all inquiries and orders will receive prompt attention.

THE ACTIEN-GESELLSCHAFT FRITSCHE PHOTO-ABTHEILUNG, of Leipzig, send us a price list of their photographic specialties, which include mounts, albums, and Vidil and cut sheet films. The list is tastefully arranged and profusely illustrated, and appears to contain the latest productions in mounts and albums at very reasonable prices.

"GOLDONA" MANUAL is the title of a booklet issued by Messrs. J. J. Griffin and Sons, Ltd., of Kingsway, London, W.C., which gives clear and concise instructions for working their "Goldona" paper, together with two illustrations, one showing the depth to which printing should be carried before fixing, and the other, the final result. All users of this paper would do well to obtain a copy of the booklet, which will be sent free to our readers on application, and a careful perusal should enable them to overcome any difficulties they may have met with in working this or other self-toning papers. Free demonstrations and lectures on "Goldona" are given in the exhibition room at Messrs. Griffin's rendezvous, on Wednesday afternoons at 3.30, to which all visitors are welcomed.

SECOND-HAND APPARATUS.—MESSRS. SANDS, HUNTER, AND CO. have just issued a new list of their second-hand goods, which includes a large variety of cameras and lenses, by practically all the best makers, enlargers and reducers, changing-boxes and roll-holders, shutters, and a quantity of sundries and accessories too numerous to mention. All goods are listed at a price much below the original cost, and we think those who intend purchasing any kind of photographic apparatus would do well to visit Messrs. Sands, Hunter, and Co.'s establishment at 37, Bedford Street, Strand, W.C., or to send for a copy of this list before purchasing elsewhere.

THE JUNE ISSUE of the Gaumont Company's "Elge" list contains particulars of the latest additions to their cinematograph films, some of which possess a special interest at the present time. The company state that they have obtained sole rights for the reproduction in film form of the Bury St. Edmunds pageant, now taking place, and this, together with the Oxford pageant just past, will doubtless be in great demand by all cinematograph entertainers. The Gaumont Company also draw attention to their hiring department, and to some bargains in second-hand films, which they are offering at greatly reduced prices, particulars of which may be had by applying to the company at Chrono House, 5 and 6, Sherwood Street, Piccadilly Circus, London, W.

## Meetings of Societies.

### MEETINGS OF SOCIETIES FOR NEXT WEEK.

SATURDAY, JULY 13.

Edmonton and District Photographic Society. Outing: Ponders End to Enfield Lock.  
Chelsea and District Photographic Society. Outing to Leatherhead.  
Aberdeen Photo Art Club. Outing to Fough, Banchory.  
Borough Polytechnic Photographic Society. Outing to Bookham.  
North London Photographic Society. Outing to Richmond.  
Hackney Photographic Society. Outing to Broxbourne. Ladies' Day.  
Rugby Photographic Society. Visit of Northampton Society to Rugby.  
Handsworth Photographic Society. Excursion to Cannock Chase.  
Manchester Amateur Photographic Society. Outing to Chapel-en-le-Frith and Cooombe.

SUNDAY, JULY 14.

L.C.C. Staff Camera Club. Outing to Oxshott.

MONDAY, JULY 15.

South London Photographic Society. Monthly Competition—(Prints).

TUESDAY, JULY 16.

Manchester Amateur Photographic Society. "Self-Toning Paper." A. G. Thistleton. "P.O.P." F. Eastwood.  
Hackney Photographic Society. "Animals of the Zoo." F. E. Roope and Walter Selfe.

WEDNESDAY, JULY 17.

South Suburban Photographic Society. Portfolio Chat and Criticism of Prints.  
Leeds Camera Club. "Cloud Photography." Discussion.  
Bristol Photographic Club. Outing to Frampton Cotterell.  
Worthing Camera Club. Outing to Arundel.  
Evertown Camera Club. Half-Day to Storeton.  
Edmonton and District Photographic Society. "Characteristics of Modern Developers." A. E. Worfolk. Competition, June 29 Prints.  
Manchester Amateur Photographic Society. Outing to Moreton.  
Borough Polytechnic Photographic Society. A Demonstration of Mattos Materials. Mattos, Ltd.

THURSDAY, JULY 18.

Hackney Photographic Society. Outing to Guildford.

## Commercial & Legal Intelligence.

**PHOTOGRAPHER CHARGED.**—Frank Dudley (64), photographer, who was very respectably dressed, was charged, at the Stafford Quarter Sessions, with having obtained a quarter-plate camera and outfit from Mr. Albert Perry, tailor, Uttoxeter, by false pretences. Mr. B. C. Brough prosecuted. Mr. Perry said he had the camera and outfit (which originally cost 17 guineas) for disposal, and he advertised it for sale in a photographic journal. He received a reply from Bournemouth, in the name of George Rivers, whose communication represented him to be an artist and photographer. Prosecutor offered to sell the outfit for seven guineas, and upon the representations made by the correspondent, the outfit was sent to the address at Bournemouth. Prosecutor afterwards received neither money nor answers to letters he sent to "Rivers." Evidence was given that the parcel despatched from Uttoxeter was received by prisoner, who subsequently pawned the goods for £3. The Inspector, in reply to prisoner, said that Dudley had given every assistance in the recovery of the property. At this stage the prisoner pleaded guilty. Mr. Brough said that prisoner was wanted by the Shropshire and other police. The Chairman said this was prisoner's first offence, and the Court felt justice would be met by committing him to one month's hard labour.

**PHOTOGRAPHERS AND LICENCES.**—At the Blackpool Police Court it was stated of George Quarumby and William Taylor, who were charged with peddling without a licence, that they were going from door to door in Charley Road with a camera, asking if occupants would have their photographs taken. The Chief Constable did not press the charge, and defendants were dismissed on paying the costs.

**TELL-TALE PHOTOGRAPH.**—During the hearing of a case at the Lambeth County Court, in which the defendant failed to appear, the plaintiff produced an illustrated paper, and said: "Here he is, your Honour, in a picture, which shows that he was at Henley yesterday."

**AN UNENVIABLE RECORD.**—At the North London Police Court last week Henry James Cray, aged 34, photographer, of Markhouse Road, Walthamstow, and Edward Brunjes, of Harries Street, Walthamstow, were charged with behaving in such a manner as to be calculated to cause a breach of the peace. A police inspector stated that he saw the prisoners pushing against young women, whom they disturbed

with offensive attentions. The prisoners denied any intention of annoying anybody. They admitted that they had had some difficulty but were surprised when they were taken into custody. Insp. Summerfield stated that he was inclined to think that there was some motive in Cray's actions, as he had been several times convicted of theft. Cray said he went out on business on Monday, when he accidentally met the other defendant, and they had a few words together. Cray was fined 21s. and Brunjes 10s. 6d.

**ALLEGED DAMAGES.**—In the Court of Session, Edinburgh, last week the Lord Ordinary was informed of the settlement of the action of Charles Sweet, photographer, Rothesay, against William Caird Muir, draper, Montague Street, Rothesay, for £700 damages for the cost of restoring his property at 19, Battery Place, Rothesay, which, it was alleged, had been irretrievably damaged by defender's building operations. By the terms of the agreement defender was granted absolver, no expenses being due to either party.

**CLAIM FOR WAGES.**—John Bickerstaffe, photographer's assistant, 89, St. Luke's Road, Southport, summoned Frederick Dodd, tenant, 31, Old Haymarket, Liverpool, for payment of £5 15s. 9d., wages alleged to be due to him. Defendant did not appear. Claimant said he had been engaged by defendant to manage a photographic shop opposite the Prince of Wales Hotel. Defendant transferred the business, and the sum claimed then remained owing to him as wages. An order for payment in fourteen days was made.

### NEW COMPANIES.

**CITY PICTORIAL WORKS.**—July 1, by Jordan and Sons, Ltd., Chancery Lane, W.C. £1,000 (£1). To acquire the business of photographic enlargers, artists, and printers, etc., carried on by A. Smith and H. Craeley, at 59-61, Queen Street, Cardiff. No public issue. First directors (not less than two nor more than five) to be appointed by signatories. Twenty ordinary shares. 55, Queen Street, Cardiff.

## News and Notes.

**DECEASE OF MR. J. T. CHAPMAN.**—One of the oldest dealers in the photographic trade, in the person of Mr. J. T. Chapman, Albert Square, Manchester, has now been lost to us through death on the 28th ult.

**BAIT OF THE FREE PHOTOGRAPH.**—A Dalston photographer offered as an advertisement, to photograph free any baby between months and five years. His place was soon besieged with mothers and their offspring. In all he succeeded in photographing babies.

**THE NEW RADIUM.**—M. André Lancien, the discoverer of molybdenum, or the new radium, as it is called, is a medical student at Rochefort. He says he has been studying photography for about two years, and in the course of experiments he combined molybdenum and uranium by treating nitrate of uranyl with molybdate of ammonia, thus obtaining a white precipitate, which, being dried in vacuum, yielded molybdate of uranyl. This substance affects photographic sensitive plates, and has been named molybdenuranyl. Its radio-activity is very low, reaching a maximum of 40, as compared with 1,800,000 of radium bromide, but, on the other hand, the new substance appears to produce no burning of the skin, and thus, besides being far less costly, offers a double advantage over radium bromide in cases in which only a low degree of radio-activity is required.

**MARK TWAIN'S PHOTOGRAPH.**—Mark Twain, who was the guest of the Savage Club on the 6th inst., was presented, by Mr. E. Peacock, with an excellent portrait of himself, executed by Mr. Ernest H. Mills and signed by all the members present. In thanking the donors for their gift, he said: "I am very glad indeed to have that portrait. I think it is the best that I have ever had, and there have been opportunities before to get a good photograph. I have sat to photographers twenty-two times to-day. Those sittings, added to those that have preceded them since I have been in England—if we average at that rate—must have numbered between 100 and 200. This is the best I have had."

**CAMBRIDGE PHOTOGRAPHIC CLUB.**—The fifth annual meeting was held on June 25, when there was a good attendance of members and

friends. The secretary, in presenting the annual report, stated the past year had been a very successful one in all ways—in membership, in attendance at the meetings, and in the interest manifested. The club had made very distinct progress, and at no time since its commencement had there been more life and vigour at present. During the year sixteen meetings had been held at which lectures, demonstrations, etc., had been given, twelve of which had been undertaken by their own members. The exhibition had been a great success. The treasurer, in submitting the statement of accounts for the year, said that the club was entirely free from debt of any description, and had a substantial balance in hand. Both report and balance-sheet were adopted. The officers for the year were then elected, the president (Mr. W. Farren), the president (Mr. C. H. Nicholl), and the secretary (Mr. Sowdon) re-elected, with Mr. W. C. Squire (treasurer) and Messrs. J. Coulson, S. J. Parson, J. H. Leech, W. Tams, D. J. Scott, Barrett, and A. Farren forming the new committee. The proceedings closed with votes of thanks to the officers both past and present.

**SUMMER HOLIDAYS** is the title of the Great Eastern Railway Company's handbook for 1907, in which special prominence has been given to some of the less known districts in East Anglia and to the country between Cromer and the Norfolk Broads. It is profusely illustrated with facsimile water-colour drawings and pen-and-ink sketches, and contains much useful information respecting the objects dealt with, together with a sketch map of the broads and a comprehensive list of golf-links in the eastern counties. The booklet is well worth perusal by those who intend spending their summer days in any part of the district which it covers, and copies may be obtained from the publishers, at 30, Fleet Street, London, E.C.

**BROMIDE ENLARGEMENTS.**—Mr. Henry M. Ward, of Leicester, whose reputation for enlargements is well established in the photographic trade world, sends us examples of his latest achievements in "toned bromides," a subject to which he has devoted special attention for a number of years. These subjects, which include portraits, interiors, animals, statuary, etc., vary considerably in subject, but all alike show a richness of colour and delicacy of gradation which is altogether admirable, and one looks in vain for any of the harsh contrasts so frequently met with in bromide enlargements. The rich sepia and velvety-purple blacks might well be taken for carbon, and the name of "carbon bromides," which they give them, seems to us extremely appropriate. We feel that any of our readers who entrust their enlarging orders to Mr. Ward will be quite satisfied with the results, and a trial will convince them of the excellence and exceptional quality of the work. Mr. Ward's address is 9, Belgrave Road, Leicester.

**THE YEAR 1905** saw a phenomenal rise in the price of platinum and a greatly increased production in the United States (says "The Mining American"). The annual report of the United States Geological Survey on the production of platinum, prepared this year by Mr. F. W. Horton, contains details of exceptional interest. It states that early in March, 1905, the price of ingot platinum advanced from 78s. an ounce to 84s. an ounce, surpassing gold in value. On May 11, 1905, the price fell to 82s., and remained firm at this quotation until February 1, 1906, when it jumped to 100s. an ounce, where it remained until September 1, 1906, when it leaped to the unprecedented value of 123s. an ounce. Mr. Horton's report also shows that the production of platinum in the United States increased from 100 ounces in 1904 to 318 ounces in 1905.

**DRESDEN INTERNATIONAL PHOTOGRAPHIC EXHIBITION, 1909.**—We think that much interest has been awakened in the above exhibition by the announcement that it will be held under the patronage of His Majesty King Frederick August of Saxony, and that H.R.H. Prince John George will act as president of the honorary committee. It is intended to issue a comprehensive programme in several languages early in September. All information may be obtained from the office of the exhibition, Dresden-A., Neumarkt, 1, Hotel Victoria, Berlin.

**ANNUAL OUTING OF THE ROTARY COMPANY, LTD.**—The employees of the above firm visited Hastings on July 6, on the occasion of their annual outing, and were fortunate in being able to enjoy a day free from rain. The numbers were rather reduced, owing to the early season having commenced; but a contingent numbering some

350 were present, and appear to have taken full advantage of the arrangements made for their benefit. Luncheon was provided in the St. Leonards Pier Pavilion, after which the party separated and spent the afternoon in the manner which appealed most to their individual tastes, tea being provided at special charges at all the establishments of Messrs. Atkins Bros. and Cox, on production of the firm's programme. This programme consisted of an eight-page booklet, containing all information necessary to keep in touch with the day's proceedings, the cover being printed on "Rotograph" bromide paper and ornamented with views of Hastings, the whole providing an interesting souvenir of the outing.

**THE "RAJAR" CAMERA**, offered monthly by Messrs. Rajar, Ltd., of Moberley, Cheshire, for the best print on "Rajar" P.O.P., has been awarded to A. E. L. Vial, Esq., 5, Dulverton Road, Leicester, his entry having been judged the best received during June. The paper on which the print was made was purchased from Messrs. Wands, Chemists, Leicester.

**THE NATURALIST'S STAND.**—Under the above name Messrs. Sanders and Crowhurst are placing on the market a new form of tripod, specially designed for photographing birds' nests, flowers, seashore objects, etc. The legs, which are 21 in. high, fit into a tilting table, thus enabling the camera to be inclined at any angle, and the top, measuring 8 in. x 7 in., is covered with a cloth, the whole being finished in dull green. The tripod is very strong and rigid, and though only weighing three pounds, is capable of supporting any ordinary half-plate camera fully extended. The price is 18s. 6d. Further particulars may be obtained from the makers, Messrs. Sanders and Crowhurst, 71, Shaftesbury Avenue, London, W.

**THE STRANGE ADVENTURES OF Emerich Dorsay**, a Hungarian photographer, are now forming the subject (says the Central News) of diplomatic notes which are being exchanged between Budapest and Cairo. Dorsay set up in business some years ago in the Egyptian capital and gained a high reputation among the members of the European colony. He was eventually appointed Court photographer to the Khedive, and in this capacity was largely patronised by Prince Mahmud. Dorsay alleges that the Prince ran up a large account, and that when he respectfully hinted at payment he was promptly arrested and thrown into prison. He managed to make his escape and reached Budapest in a state of destitution. He laid his case before the police, an unhappy step to take, for the police surgeon declared he was mad, and the luckless photographer speedily found himself in a lunatic asylum. Fortunately for him it occurred to the Budapest police to investigate his story, which, it is now stated, they have discovered to be true, and the Austro-Hungarian Consulate in Cairo is taking steps to obtain satisfaction for the long-suffering creditor.

**SECRETARIES OF SOCIETIES** who are now preparing their programme for the winter session may be glad to learn that Messrs. Kodak, Ltd., are arranging for their Mr. W. F. Slater to give a lecture on "The Theory and Practice of Time Development," accompanied with practical demonstrations of their daylight developing tanks, etc. Those desirous of securing this for one of their meetings should communicate at once with Kodak, Ltd., 57 to 61, Clerkenwell Road, London, E.C., in order that suitable dates may be arranged.

**SOUTH SUBURBAN PHOTOGRAPHIC SOCIETY.**—Only eighteen out of the 150 members of this society attended at the Society's rooms, 75, High Street, Lewisham, on Wednesday evening for the discussion on bromide printing opened by Mr. Philibert Melotte. Mr. P. B. Danatti presided. Mr. Melotte is engaged in the Photographic Department at the Royal Observatory, Greenwich, where at least a ton of hypo and many thousands of sheets of bromide paper are used in the course of the year. Hence he was able to give the society much curious information not generally known to amateur photographers about the exposure and development, and the eccentricities and peculiarities of bromide papers and developers. Amongst other things he said that as a matter of experience he found the correct exposure of bromide paper in winter was double that required in summer; but to show the latitude obtainable in exposure he produced three prints, exposed respectively for 30, 40, and 50 seconds, and developed with amidol, the result in each case being almost identical. Another point he emphasised was the possibility of developing bromide prints with practically any known developer. In proof of this he showed a number of prints developed with a variety of

developers—including pyro-metol—and all yielding approximately the same result, with very little to choose between them. Amidol apparently gave the most satisfactory print; but he cautioned the members against attempting to develop an under-exposed print with amidol. For forced development of that kind he preferred metol-hydroquinone. Among the bromide prints shown at the meeting were a couple of framed enlargements of architectural subjects by Mr. Percie Edwards, and several toned enlargements made by Mr. W. C. Chaffey and Mr. F. N. Palmer, from negatives obtained at the Epping outing.—The secretary reported that the Epping excursion was thoroughly enjoyed by those who attended, mainly owing to the help and hospitality extended to the members by Mr. J. T. Ashby, F.R.P.S. Mr. Ashby guided them to the best views in the Forest, and after tea invited them to his house, where they discussed pictorial photography.

CHANGE OF ADDRESS.—The Tella Camera Co., formerly of 110, Shaftesbury Avenue, announce that they have moved to larger premises at 68, High Holborn, W.C., where all future communications should be addressed.

## Correspondence.

\**Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*

\**We do not undertake responsibility for the opinions expressed by our correspondents.*

### TIMES IS HARD.

To the Editors

Gentlemen,—Times is hard, there is no gainsaying that, and the following style of business does not improve them. The enclosed circular was left at my private house this week, and apparently this very important firm, which gives no address, was doing a good business.—Yours faithfully,

A PROFESSIONAL.

[The circular enclosed is as follows.—Eds. B.J.]

MESSRS. STUART LANCASTER AND SON,

ARCHITECTURAL AND TECHNICAL PHOTOGRAPHERS.

Photographers to H.M. the King. Photographers by special appointment to H.M. the King of Portugal. Photographers appointed by the Admiralty to H.M. Dockyards,

have been favoured with instructions to photograph certain Houses and Premises in this district. To give pictorial and artistic effect to these photographs the tenants or their children are invited to stand outside to be photographed with the premises.

NO CHARGE IS MADE.

A proof of the photograph will be shown in a day or two.

We shall be Photographing in your Street between 12 and 2 o'clock.

Address .....

### "LUSTRALENE" AND "POISONED FINGERS."

To the Editors.

Gentlemen,—Having myself been a sufferer from fingers poisoned by chemicals (many and many is the time I have been compelled to leave my bed in the small hours and, in order to gain relief from the itching torture, plunge my hands into the hottest water I could bear), I shall have pleasure in imparting to "Fingers," who appealed to you for help in last week's "Journal," and to all other like sufferers, how I overcame the difficulty for myself.

Several weeks ago I had on my shelves a tube of "Lustralene," a preparation sold for imparting lustre to dull prints. It suddenly struck me that as the principal part of this preparation was evidently wax, if I smeared it over the fingers it might reasonably be expected to give some protection to those tortured members. I did so before commencing work each morning. By the end of the week the improvement was so marked that I forcibly felt the thrill of gladness we all experience when we have discovered the remedy for an evil that has long depressed us. For years, up to a few weeks ago, my fingers had such an unpleasant appearance, on account of the texture of the skin in its poisoned state, that I never willingly displayed them. I was simply ashamed of them. At this moment I look at them with pleasure—they are now as healthy in appearance as they ever were in my life, and I am now quite free from that horrible itching which once possessed and distressed me. Allow me to commend "Lustralene" to all my suffering fellow photographers; it in no way incommodes one in one's work, but performs its protective office—at any rate, so far as I am concerned—perfectly.

There is one suggestion I would like to make to the "Vang Company," and that is that, if they think it worth their while, might impart to this, to me, precious preparation a more pleasant odour.

In recommending this proceeding to my fellow photographer who suffer in the same way as I myself once did, I must, of course, add that even now I take all possible precautions to keep my fingers out of the solutions with which I work. Trusting that this communication will be of some value, I am, yours respectfully,

24, Lark Street, Burnley.

FRED. BRUNTON

### THE ALUM TROUGH.

To the Editors.

Gentlemen,—Indeed, we believe it has been stated that the w is the more efficient of the two." This quotation is from an Ex C note on the use of the alum trough in your last issue. But is t any ground for the diffidence implied in the "we believe"? Su Melloni and Tyndall, the first investigators of diathermancy, al went out of their way to emphasise the fact that water is sli less diathermanous than alum solution. Tables of the nume results of these investigators are quoted in almost every text-bo heat, and it is therefore somewhat astonishing that the attentio lanternists should have to be directed in this year of grace 1907 to superior athermancy of water over alum solution. May it not that the alum tank habit has arisen, not from the irresponsible st ment of any "great authority," as you suggest, but rather from unwarranted deduction from partial knowledge? It was found Melloni that alum in the solid state is, after sugar-candy and ice, most athermanous of the solids investigated. And, as is well kno this property of solid alum is turned largely to practical accoun the refrigerating and fire-protection industries. May not then installation of the alum-trough in lantern work have arisen as result of the knowledge on the part of some "practical" man, acquainted with the literature of the subject, that solid alum super-eminently athermanous; this knowledge provoking the in ence that what is super-eminently done by the solid must also super-eminently done by its solution?

I have for many years used plain water troughs in lantern w when delicate slides were being exhibited, and can answer for th protective efficiency.

Blackheath.

DOUGLAS CARNEGIE

### THE EFFICIENCY OF IRIS SHUTTERS.

To the Editors.

Gentlemen,—Two points dealt with in Mr. Anderson's letter see to me very debatable. First, with regard to the use of stops. M Anderson cannot conceive of any hand camera worker stopping do beyond f/8, and therefore he does not think the effect of aperture any moment. The modern hand camera lens generally has an apture of f/6, but if it is used for marine work (and this is a most popul branch of hand camera work) it has to be stopped down to f/16 f/22, owing to the fact that the majority of lens shutters will not gi a higher speed than about 1-34 sec. The average speed for this ty of work in fine weather is about 1-50 at f/16, therefore stopping do is necessary. I often use f/22 myself, hence the apertures to be co sidered, so far as they affect shutter exposures, range from abo f/6 down to f/22, and this series is quite long enough to give marke differences in efficiency. In my former letter I considered a serie down to f/64, but only for the purpose of illustrating the comparativ effects with the two shutters. As to the marking of the speeds, I a quite in agreement with Mr. Anderson with regard to the wron marking so prevalent. I can see no excuse for marking a series fro about 1-15 to 1-100, when, as a matter of fact, the shutter has prac tically only two useful speeds of perhaps 1-17 and 1-35. As a rul the highest speed is only about twice the lowest. I do not, howeve agree with him in thinking that the effective exposure should be marked in preference to the duration. The ideal would be to mar both, but if one only is provided I should prefer that to be the dura tion. High efficiency is, of course, desirable, but this affects exposur only, and in hand camera work we cannot calculate exposure to a great deal of nicety, and we have to trust a great deal to the latitud of the plate. The duration of the exposure is, however, an importan matter with moving objects, and there is no saving clause here. If the exposure is twice as much as it ought to be, a moving object is badl blurred, though the plate is not hopelessly over-exposed. Hence I prefer to have the duration marked accurately. High efficiency is

wanted, but I am not particular as to the exact amount of the exposure.

his leads to another matter in which the iris shutter has an advantage. The marked duration of the exposure is correct for any with the iris, but only correct for one stop with the other form shutter. When you stop down with the blind shutter the duration of exposure is reduced unnecessarily, though the efficient exposure remains the same. If you could lower the speed so as to allow for you would gain in efficiency and make the blind shutter nearly effective as the iris shutter, but such adjustments are too troublesome in practice.—Yours, etc.,  
C. WELBORNE PIPER.

#### ILLUSTRATIONS WANTED.

To the Editors.

Gentlemen,—The undersigned ventures to address you on the following subject, viz. :—

the years 1855 and 1856 the British Foreign Legion was stationed at Shorncliffe, Aldershot, Colchester, and Bournemouth, near Portsmouth. Their disbandment about 2,100 officers and men volunteered for the Colony. Writer of these lines is one of the few left of the men; he also served in India subsequently to coming to the Cape, helped to put down the Mutiny. He is at present a pensioner, still engaged in agriculture. He is writing a history of the British German Legion, German and Military Settlers, and Volunteers in the Indian Mutiny, and has collected a lot of material for the purpose.

What is wanted are some illustrations, groups of officers, and generally, views of the camps at Shorncliffe, Aldershot, etc., as it was in the year 1856. Although no personal profit is to be derived from publishing the history of the B.G. Legion, but all goes towards the work among the natives of these parts, yet I offer some good photographs of colonial scenery and native life to any photographer at the aforesaid places, towns, etc., in return for some old photographs taken about the year 1856, or even earlier. I am quite sure there are some good pictures in existence, and if you would be so kind as to insert a short notice in the BRITISH JOURNAL OF PHOTOGRAPHY, my object would be realised. As it is a matter of English history and that of Cape Colony I hope some patriotic photographer will come to my help.

Thanking you in anticipation of your assistance.—I am, yours

C. C. HENKEL, J.P.,  
Late Conservator of Forests.

## Answers to Correspondents.

*Matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington Street, Strand, London, W.C."* Inattention to this ensures delay.

*Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*

*Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington Street, Strand, London, W.C.*

*For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington Street, Strand, W.C., undertake the registration of copyright photographs at a charge of 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the application.*

#### GRAPHS REGISTERED :—

Small, 43, Norton Road, Stourbridge. Photograph of Sleepy Mill, Leys. (3)  
D. & Watson, Station Road, Hinckley, Leicestershire. Photograph of Needham.

T.—We know of no such paper as you require, but any bromide paper manufacturer would coat you some, particularly if you are prepared to take large quantities, as you say. The price would naturally depend upon the quantity.

P.—Yes, "pottasche" is the German for potassium carbonate.

QUESTIONS.—1. Where can the dye known as filter yellow K be obtained? 2. What is the price of the dye? 3. Is gamboge soluble with methylated spirit?—W. MACARTHUR.

Fuerst Bros., 17, Philpot Lane, London, E.C. 2. 2s. 6d. half-ounce. 3. Gamboge is almost entirely soluble in methylated spirit.

RED BATH.—Some time back you gave a formula for a combed bath containing alum, which enabled the prints to be

washed with hot water. I have been unable to find this, and shall be glad if you can give the reference or repeat?—POSTCARDS.

The formula will be found on page 776 of the "Almanac" for 1907, and it runs as follows :—

Hypo .....	5 ozs.
Sodium bisulphite lye .....	100 minims.
Lead acetate .....	20 grains.
Alum .....	400 grains.
Gold chloride .....	5 grains.
Water to .....	20 ozs.

Dissolve in the above order.

BLACK MARKS ON GASLIGHT PRINTS.—I have to use a lot of glossy gaslight paper for making copies of plans, and find that I get a lot of fine black marks on the whites. What is the cause, and how can I prevent or remove them?—PETERBOROUGH.

The marks are due to friction, and it is extremely difficult to avoid them. They may be prevented by adding from 30 to 60 minims of a 10 per cent. solution of potassium iodide or cyanide to every ounce of the developer. They can generally be removed by rubbing the print with a pad of cotton wool dipped in methylated spirit.

LENS WANTED.—I am about to commence business and am having a studio built which will be fifteen feet long and nine feet six inches wide. Will you kindly let me know in the "Answers to Correspondents" page what inexpensive lens I should get? I have a good whole-plate camera, and I shall want to take whole-plate pictures, cabinet groups, and midgets.—NORTH LIGHT.

No inexpensive, or costly one for that matter, is made that will do what you desire in a studio but fifteen feet long. A lens of eight inches focus requires about eleven or twelve feet between the lens and sitter for a full-length or group cabinet portrait. Such a lens will not, of course, do for whole plates. For those you will require one of about 12 or 13 inches focus, which will also be suitable for large cabinet heads. We think you are unwise in building so short a studio for professional portraiture.

UNRULY APPRENTICE.—I have got a lad as an apprentice for three years, and I can do nothing with him. He will not do what I tell him. He "cheeks" me, and tells me I cannot sack him as he is bound for three years. Will you kindly say what I can do in the matter, as he has only served nine months out of the three years, and I am sure I cannot put up with it for the remainder of the term? I had a small premium with him.—MASTER.

You have a very simple remedy. Take the lad before the local magistrate and state the circumstances. The magistrate has the power to cancel the indenture, and that will end the matter.

C. R. SMART.—We cannot possibly advise you without knowing more. If you like to write describing the process, we will treat it as confidential and then advise you. The idea may be valuable or it may, of course, be very old.

PHOTOPLASTIC PROCESS.—I desire as much information about photoplastic as I can get, or even the swelled gelatine process would be an aid. I was told that an article appeared in the "Almanac" three or four years back, giving the photoplastic process pretty completely as practised by some French firm; but on looking through the Almanac back to 1898 I could find no reference to the subject at all, so I thought I had better write you and hope you can aid me.—D. RUTHERFORD.

Notes on photoplastic or relief photographs appear on p. 818 of the "Almanac" for 1907, p. 845 of the "Almanac" for 1906, and "B.J.," June 30, 1899, p. 408.

J. ALLEN.—There is no directory in print now. One was published about ten years ago. You might possibly find what you want in Kelly's Directory of Chemists and Druggists.

J. ROSE.—It entirely depends upon the light you want to use, the aperture of the lens, and the plate. No one can answer such a vague question.

E. LEUTNER.—We are sorry that we cannot publish your letter, as it would open up a controversy which we do not think suited to our pages.

MILTON.—What do you mean by "register"? Unless it is a design you cannot register; if it is a process, then you can patent it. Write more fully.

**H. T. CAVE.**—Your best plan would be to send to "Country Life," the "Sketch," "Tatler," and the "World and His Wife."

**WET PLATE.**—We should not advise you to abandon the substance for the shadow. Wet collodion is much used for process work and reproduction, but chiefly for half-tone negative making. If you attended the classes at Bolt Court and learnt this you would stand a better chance.

**TONING.**—Lately I have had trouble with the toning of P.O.P.s in sulphocyanide bath, and shall be much obliged if you can help me in tracing the cause. The prints, soon after immersion in the toning go a sickly yellow, and although after a time they turn a reddish brown, they will not tone fully, being a very yellow colour by transmitted light, and fixing to a yellow; addition of more gold does not make the slightest difference, it seems impossible to tone them beyond a yellowish brown. The bath is composed of 30 gr. sulphocyanide to 3 gr. of gold, and is mixed up some time previous to use, so as to ripen. I have used this formula for many years, and have never had any trouble until lately, and am at a loss as to the cause. I should be much obliged if you would give me your opinion on the following questions:—1. Does the amount that a print is toned, as long as it is thoroughly fixed, affect its permanence? 2. Are P.O.P. prints toned to a reddish brown in acetate soda 1 oz., gold chloride 15 gr., as permanent as those toned in sulphocyanide?—**PUZLED.**

We can only suggest that the bath is not properly mixed, or not allowed sufficient time to ripen. The proper way to mix the bath is to dissolve the sulphocyanide in half the total bulk of boiling water, dissolve the gold in the remainder boiling, then gradually add the gold solution to the sulphocyanide, stirring well, and allow to cool. When cold it will be ripe and fit for use. 1. No. 2. Certainly. The amount of gold deposited in toning has no practical influence on the permanence of the prints. It is the elimination of the hyposulphites which chiefly conduces to permanence.

**STUDIO QUERY.**—I have a sitting-room 21 ft. x 15 ft., with a French window (opening outwards) 10 ft. high by 8 ft. wide. Could you suggest reflectors and screens suitable to make a studio of it, and how high to screen up the window. Unfortunately the latter is very near the background. I should like to make the reflector and screens, if possible.—**STUDIO.**

We should advise you to make the window fitted with three curtains running horizontally on rods or wires—say 4 ft. long each. Then you could arrange the height of the light according to the effects desired. The colour of the curtains may be of a light blue or buff colour. A suitable reflector would be one about 6 ft. by 4 ft., covered with white or very pale blue paper. The sketch shows but a very small space between the side of the window and the end of the room. Therefore we should advise you to work the room somewhat diagonally, by placing the camera very near the side of the room and the background at right angle to it, and as far back as you can get it.

**LIGHTING, ETC.**—A customer got a proof, which was returned marked "Satisfactory," and instructions to finish one dozen cabinets therefrom. Two days later the customer and a photographic friend (I have presumed an amateur) called to cancel order as sitter was lighted wrong, the so-called complaint being that the subject was lighted from side and top, and lighting should have been from the back, and on no consideration would cards be accepted. This is the first I have heard tell of a subject being lighted from behind, and I shall be pleased if you can tell me (because photographic friend spoke with such assurance that I felt bewildered, although a lot of his talk was nonsense) whether there is such a style of lighting. 1. Is there such a style of lighting; and if so, how is it done; or is there any book I can get dealing with the same? 2. Can I compel full payment, as order was given after proof was submitted, and especially as I have five prints from negative? 3. Can you give any other suggestion in the matter? 4. Can you give me formula for making collodion enamel for glazing prints? I have tried the following, but it is so opalescent that it is useless—viz., 50 gr. pyroxyline, 4 oz. alcohol, 4 oz. ether, 15 drops castor oil. 5. How is high gloss on enclosed print obtained? I have tried ferrotype plates, and glass

cleaned with chalk, etc., but fail to get such high glaze. **AVONDALE.**

1. There certainly is a method of lighting from behind, which is usually known as Rembrandt. You will find full details in "The Studio, and what to do in it," by Robinson, "The Lighting in Photographic Studios," by Duchochois, "Professional Photography," by Hewitt, No. 2 of the "Photo Miniature," "Artistic Lighting," by Inglis. 2. We think that you would have good cause for claim for the work done at the time the order was cancelled. 3. We should suggest writing a polite letter to the sitter, pointing out that the order was partly completed, and suggesting that this must be paid for; if this produces no satisfactory reply, we should proceed. 4. Probably the pyroxyline is at fault, as the formula should give a perfectly clear structureless film, but we should prefer to use the castor oil, which serves no purpose. 5. The print has obviously been squeegeed to waxed glass. If you wax the glass, which must be plate, and polish with a rag, and then squeegee the prints after hardening, you should get the high glaze.

**POSTCARD.**—You would certainly be justified in refusing the card, and we should advise you to inform the firm that, if sent, you will not accept delivery.

**MAKING POSITIVES.**—I have some half-plate negatives which I should like to obtain again, and which I should like to duplicate. Would you kindly let me know what kind of plate to use, best for making the positive and negative; the best developer for the work; whether to expose the plate in frame to a light, through a camera by reduction?—**H. M.**

The best plan would be to make the positives by contact, using an ordinary dry plate, and a soft working developer, such as metol, rodinal, or pyrocatechine. Formulae for these will be found in the "Almanac."

**PRINT WASTES.**—We get a tremendous waste at every turn with printing. Will you kindly give me what your ideas are as to amount of returns we ought to get—e.g., if we give out a quantity of paper for 12 x 10 and 15 x 12 work, or say a gross of 12 x 10 cut paper—what proportion, making all reasonable allowance, ought we to get back in good prints? Or, again, say from gross of postcards? All work is either enamelled or "matted."—**PERPLEXED.**

This is a question we are scarcely able to answer, as all must depend upon circumstances. If the paper used is free from defects theoretically there should be no waste at all. It stands to reason that if the printers have to deal with a larger number of faults than they can properly attend to a certain amount of waste must be expected, especially when the light is bright, and the print goes on rapidly. We should advise you to exercise some personal supervision over your printing staff, and see where the faults, if any, lie. You will then be able to form an opinion better than we—knowing nothing whatever of the conditions under which the work is done—could possibly do. We might add that very much depends upon the class of labour you employ. If it is of the cheap kind—lads, girls, or apprentices you must expect to have far greater waste than if you employed really skilful hands. With them the waste should be next to nil.

**\*\* NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

## SUMMARY.

Photographic Convention.—The earlier proceedings are over this week. A reproduction of the group taken on Wednesday presented. The Convention will meet next year under the presidency of Sir E. Cecil Hertslet. (P. 538.)

Alfred Watkins, in his presidential address, suggests that photography is mainly the outcome of British genius. (P. 538.)

Scheffer's paper, with reproductions of his photomicrographs, is in full. (P. 540.)

Death of Mr. John Stuart, of Glasgow, one of our oldest and most respected photographers, is reported. (P. 534.)

Relation of photographers to sitters as regards the ownership of negatives is dealt with. (P. 535.)

E. W. Foxlee continues his articles on the wet collodion process, dealing this week with the all-important subject of the bath. (P. 536.)

Letter on stand development, with suggestions for a new form of tank, appears. Obviously, this method is attracting much attention. (P. 550.)

Pressure on our space has compelled us to hold over many items for next week.

## EX CATHEDRA.

**A Photograph of the Latent Image.** We stated last week that any phenomenal paper or fact was not to be expected at every meeting of the P.C.U.K. We think, however, that this year will be marked by the first appearance of a photograph of the latent image itself, which, by the kindness of Dr. Scheffer, we are able to reproduce with a digest of his paper (Fig. 9, page 541). It may be considered that this is not actually a photograph of the latent image. At any rate, it is a photograph of an image which has not been seen before, and can only be rendered visible by development. This was obtained by exposure of a gelatine emulsion to light, and subsequent fixation, without development, a process, which, as is well known, leaves behind something which is analogous to the latent image, as on it can be built a picture exactly as in the case of the true latent image. Whether this is actually a photograph of the latent image or merely the image of the gelatine in a state of strain caused by the action of light on the silver bromide, as has been suggested, we cannot say. Dr. Scheffer, however, is to be warmly congratulated on his success in photographing it.

**The Substance of the Primary Fixed Image.** As to exactly what this substance may be, there are very conflicting opinions. Possibly the best and most concise summary of all the opinions is to be found in the recently published work by Drs. Sheppard and Mees, and this concludes as follows:—"While the latent image before fixation resists nitric acid far better than silver, the primary fixed latent image behaves rather as a mixture of metallic silver and photo-bromide. Apparently, part of the subhalide is converted to metallic silver by the thiosulphate." Whether this is the authors' own opinion or a deduction by Dr. Eder, whose conclusions they quote, is not quite clear. If this assumption, that is that the "Rest" or remainder after primary fixation is metallic silver, then one can understand to some extent Dr. Scheffer's success. In any case, it is to be hoped that his researches will throw further light on the subject.

**Hydroquinone and Glass.** A dealer the other day confronted us with two packages. One was a paper packet containing one pound of hydroquinone and bearing a label to the effect that the contents should not be stored in a glass bottle. The other was a small packet containing one ounce of hydroquinone in a glass bottle. Both packets belonged to the same consignment and came from the same manufacturer. The dealer wanted an explanation, but it was beyond us; it was too much of a puzzle. If hydroquinone will not keep in glass, why send it out in glass? But perhaps an ounce will keep where a pound will not?

If that is so we should like to know why, for the reason is not apparent. Is it a fact that hydroquinone is damaged by storage in glass bottles, or is it a myth that the manufacturers have only just found out? An answer to this query would be of service to many photographers, for bottles are more convenient for storing dry developers than paper or card boxes, and most of us would prefer to turn out the hydroquinone into a bottle when we have bought it in a card box.

### The Alum Trough.

The letter of Mr. D. Carnegie in our issue of July 12 gives a very probable explanation of what he aptly terms the "alum tank habit." Unwarranted deductions from partial knowledge have played a great part in photographic matters, and, possibly, this alum tank habit is only a somewhat remarkable instance of the trouble that people will take to perform a wholly unnecessary operation that serves no useful purpose. It is certainly very curious that belief in the efficiency of the alum tank should be so widespread, and that the more efficient and far more convenient water tank should be neglected. If this one particular myth can be effectively settled, owing to Mr. Benham having drawn attention to it, something useful will have been accomplished. We wish that all the other myths that hinder the photographer in various directions could be disposed of in a similar authoritative fashion. Reference to these other myths reminds us that for some strange reason alum plays a prominent but doubtful part in many photographic operations. A list of all the troubles for which alum has been prescribed as a cure would make curious reading, and we doubt very much if some of its assumed properties and actions would stand proper investigation.

\* \* \*

### Dark-Room Aræmia.

In our issue for May 31 we inserted a note on this subject expressing a doubt as to the production of anæmia from prolonged stay in the dark-room. Herr Ocum, of the Finsen Light Institute, Copenhagen, has now discovered that darkness and red light reduce the quantity of blood by about 3 per cent. Assuming, then, that there are about five litres of blood in the average body, this would be reduced by continued working in the red light by about fifteen to eighteen cubic centimetres. With more than three hours' stay in the dark-room there is considerably less blood in the heart. His advice to dark-room workers is that they should take as frequent sun-baths as possible.

### The Correction of Convergent Distortion.

When a photograph is produced in a tilted camera, vertical lines are only shown as parallel when the camera back is set quite plumb. If the back is out of the vertical, then the perpendiculars will appear to either converge or diverge upwards. It is fairly well known that this effect can be corrected, and the parallelism of the lines restored, by copying the distorted negative in the camera and inclining either the negative or the copy until the lines become parallel. It is, however, not so well known that a distortion of another kind is introduced in this "correcting" process if certain precautions are not observed. The original distorted image not only shows convergency, but also considerable dwarfing of the heights, and if in the correcting process the negative alone is inclined, this dwarfing is very much increased. On the other hand if the copy alone is inclined, the dwarfing is over-corrected, and heights are magnified. To secure perfect correction without any errors in height, it is necessary to incline both negative and copy to certain definite angles, which vary with the scale on which the copy is being made and the focal length of the correcting

lens. If these precautions are not taken, we simplify a very obvious distortion that cannot deceive an and introduce another of a kind that cannot be detected readily, and is therefore likely to deceive everyone. precise conditions of correction can be ascertained, the aid of somewhat complex rules and formulæ, practice the following is a very simple method. Convergencies are avoided by the simple expedients of using the same lens as that which produced the distortion, always enlarging on a scale of not less than two to one. The new copy, or the focussing screen, is inclined the vertical to the same angle as the camera back was inclined when taking the original negative, and the negative is inclined in the opposite direction until the convergency just disappears. Both convergency and height are thus corrected together. If the scale of enlargement is greater than two to one, it will be found that the image improves without the aid of small stops. A bigger scale is, in fact, advantageous in all ways, and the suggested scale of two to one is a minimum. A less degree of enlargement gives an incorrect result in this simple method, in addition to the fact that it renders sharp more troublesome to attain.

\* \* \*

### An Anti-Snapshot Law.

It has been held by the Courts that a photograph of any person, provided it does not constitute a libel. There has been considerable friction on this point, particularly in the United States, where the Press photographer is particularly to the fore, but in England there are few instances of trouble. In Germany, however, law has just been passed which is somewhat drastic as it applies not only to snapshots of private persons but also to photographs of works of art, interiors of churches, etc. Damages to the extent of £300, with a fine of £50, or, as an alternative, two months' imprisonment are the penalties to which the wild snapshotter is liable. The Kaiser or members of the Royal family, statesmen, actors, and all sorts of public buildings and public works of art may, as heretofore, be photographed and reproduced without permission. It is obvious that this law may be a saving clause to the average tourist, armed with a camera, but the saving clause is that no police prosecution will immediately follow, action being dependent upon formal complaint by the party aggrieved.

### Death of Mr. John Stuart of Glasgow.

Another well-known figure has been removed by death on Saturday last in the person of Mr. John Stuart, of Glasgow. He was one of the leading photographers in the North had been for close on fifty years connected with the business in Buchanan Street, Glasgow, now carried on under his name. He was a Fellow of the Royal Photographic Society and a staunch supporter of the Photographic Convention from its inception, and was President at the Glasgow meeting in 1898. His presidential address was marked by that broad-mindedness and kindness of spirit so characteristic of the man, and, at the same time, showed him as he was, a man of wide and old experience but always interested in the very latest advances in photography. His work, widely known for its artistic and technical excellence, was marked out by that restraint which, whilst showing his appreciation of the artistic merit in photography, prevented him from descending to eccentricity. One of the most genial and kind-hearted men, ever ready with a joke, we shall sadly miss him.

## THE OWNERSHIP OF NEGATIVES.

As we have dealt in these columns with the questions of the rights and liabilities of the photographer in reference to negatives which he may take for his customers, it is evident that there are still a large number of persons who are completely ignorant of the legal points involved in the business by which they earn their daily bread. It may, therefore, not be out of place if we refer briefly to the matter, and thereby, we hope, set at rest for a time the questions which with monotonous repetition are weekly added to us. The most common relation in which a photographer can stand towards a sitter is that in which he acts as portrait taker to any person who walks into his studio and orders a dozen cabinet photographs. The photographer may suppose that when the prints have been delivered to the sitter his (the photographer's) responsibility ends. Not so; there is an implied contract to the effect that the photographer will not take or permit copies to be taken from the negative, unless he is expressly so authorised by the sitter. This tacit agreement, which is intended to be made in the case of every portrait negative, is made—or, indeed, of every negative whatever for the making of which the photographer is paid—is not contradicted by the fact that the negative is the photographer's property. So far as we are aware—and our recollection is based on over business matters in photography for a greater number of years—we do not know of any case in which an action has been sustained against a photographer for anything he has done with a negative made by him for a customer, other than something concerned with the taking of copies. The most common case has been for the photographer to have made an enlargement from a negative in possession, which enlargement he has displayed in his window. The sitter whose portrait he uses in this manner, of course, restrain him, and can equally prevent the photographer from employing the negative in other ways for the production of copies. But there, we imagine, the sitter's right stops. It has not been shown that he can prevent the photographer, for example, from smashing the negative, or that he can do anything if the photographer chooses to destroy negatives from which the sitter has been supplied with prints made. It may be easily supposed that the implied contract, upon which the relations of the photographer rest, should include the preservation of the negative by the photographer, but if a sitter ever gone to law with a photographer over this matter we have never heard of it, and in the long history of cases connected with photography we doubt if one bearing on this point has been recorded.

A question arises: What are the photographer's rights in the matter of the sale of negatives taken in the circumstances to which we are now alluding, that is to say for a purpose in the ordinary course? Undoubtedly the sale of negatives would confer upon the purchaser no other rights in the negative than were possessed by the photographer by whom the plates were exposed. The purchaser would merely print or enlarge to the sitter's order or with the sitter's sanction, and if he transgressed in either of these particulars the law would not exculpate him because he is not the person who entered into the contract in the first instance. We cannot recall any case in which such an action as this cropped up, but it is difficult to imagine the course being followed in the event of such an infringement of the sitter's right being committed.

It needs to be impressed upon many photographers that the limitation of the use which they make of the negative—its use as countenanced by the sitter—applies equally to other photographic negatives. It holds good of equal force in the case, say, of a photograph which

is taken of a football group to the order of the club committee or of the secretary, to that of a piece of furniture made by order of a firm of cabinet-makers, and in any case where the photographer is recompensed for his work by the party for whom the work is done.

Arising out of this general statement is the case in which certain negatives out of a number taken for the sitter are rejected by the sitter as unsuitable. To whom belongs the right to make use of such negatives, to the sitter or to the photographer? We know of no case in which this point has been settled in reference to landscape or other "technical" photography, but in regard to portraiture the law is clear. It has been held that the payment which a photographer receives is for the attempt which he makes as an artist to provide the sitter with a satisfactory likeness, and therefore any negatives which the sitter may choose to reject for printing purposes are nevertheless considered as within his control, and are to be used by the photographer only as he (the sitter) may permit. In short, the surplus negative is exactly on all fours with the negative from which the sitter's orders are executed.

So far we have dealt with the liabilities and limitations of the photographer. We must now turn to his rights in reference to the negatives which he produces, and it is found that the photographer does possess a very distinct right, namely, the right to retain the negative which he makes of a sitter or of any scene or object for photographing which he receives adequate payment. This point was settled long ago in a number of cases, but of late years a still more important issue of the same principle has been decided in the High Courts. It was a case in which a photographic firm, in order to carry out certain work of printing with which it had been entrusted, prepared a number of duplicate negatives from that placed in their hands by the customer. These duplicate negatives were duly charged for, and were then claimed by the customer as his own property. The decision of the Court, however, gave the custody of the negatives to the photographers on the ground that they were part of the work done by them in order to carry out the customer's order.

It should be pointed out that the above considerations are not based upon the copyright law. Although there is a very clear condition in the Copyright Act with respect to the proprietorship of the copyright in a photograph taken by a photographer who is paid, or ought to be paid, for certain work, yet the law of the ownership of the negative does not depend on this but on the law of contract, and on that important factor in all business relations, the custom of the trade. The position in which a photographer is placed with respect to copyright has been so often the subject of examples in our correspondence columns that we could scarcely believe that it could be misunderstood by any professional portraitist did we not receive constant documentary evidence of the fact. The question crops up constantly in all sorts of business transactions, consideration of which we must defer for some notes in an early issue.

---

PHOTOGRAPHY IN THE COLONIES.—We are glad to note that there appears to be a rapidly increasing interest in photography in the Colonies, and that the number of both professionals and amateurs has been considerably augmented of late. With a desire to help its amateur readers, the "Daily Colonist," published in Victoria, B.C., has arranged to devote a section of its Sunday edition to the subject, and Mr. Arthur V. Kenah, who has been a contributor to our own pages, has been placed in charge of this department. Mr. Kenah has had many years' experience in all branches of photography, and his writings will doubtless prove both interesting and instructive to those interested in the subject. A special feature will be made of "Answers to Correspondents," and Mr. Kenah will place his services at the disposal of those requiring his help.

## THE WET COLLODION PROCESS IN PRACTICE.

[In continuing the two preceding articles of this series, in which the preparation of the glass plates and of the collodion has been dealt with, the following deals with the silver bath. Its immediate successor treats of the development. The aim of this series is to present essential points in the working of the process.—Eds. "B.J."]

AFTER the collodion, the next subject for consideration is the silver bath. Before, however, going into this matter it will be as well to say a few words about the vessels in which it is usually contained. For small sizes—say, up to 12 by 10—the ordinary glass dipping-bath, with a glass (or, better, a silver wire) dipper, is the most general. The latter form of dipper has the advantage that there is no risk of the plate slipping off it when put into the solution, and then, possibly, cracking the bath. The glass bath should be enclosed in a wooden casing, with a loose-fitting cover to keep out light and dust. In size it should be a little larger than the largest plate that is to be sensitised in it, so as to permit of its being moved a little laterally while in the solution, as that facilitates the avoidance of streakiness when the solution is in a certain condition.

### Developing Dishes.

For the larger sizes trays are preferable. On the Continent ordinary flat trays, or dishes with wooden covers, are usually employed. In this country what are sometimes called wave-baths are more generally used. These are made of wood with a waterproofing lining, such as asphaltum or paraffin wax. At one end is a well to hold the solution when it is raised up. These baths are mounted on trunnions on a frame, the trunnions being so pivoted that when the bath is reared up—say, to an angle of 45 degrees—it retains its position by the weight of the liquid at that end. When placed flat it remains so by reason of the weight of the solution covering the whole of the tray. These baths are usually fitted with a light hinged lid covered with American cloth. The plate is put into the bath so as to rest upon pegs or a ledge, just above the well, and the lid then closed. The bath is then lowered to the horizontal position, when the solution flows over the plate in one even wave. The vessel can then be tilted up and down to facilitate the washing away of the ether and alcohol from the collodion film. When the plate has been sufficiently sensitised the bath is simply raised and the plate is left draining. As during this time it is enclosed in a moist atmosphere there is no fear of its drying. In this vessel the plate may be left for half an hour or more without suffering injury, or without risk of its yielding in the negative what are commonly known as "oyster shell" markings. It is for this reason that I personally prefer this form of bath to the ordinary dipping one, even for small plates. It has, however, one disadvantage, which is that it, in use, necessarily takes up much more room in the dark-room than does the ordinary dipping-bath.

### Preparing the Silver Sensitising Bath.

It is, I think, needless for me to mention that the sensitive salt, the iodo-bromide of silver, in the collodion film is brought about by a double decomposition. The collodion contains iodide and bromide haloids, which in the nitrate of silver solution are converted into the iodide and bromide of silver.

In compounding the silver bath it is imperative that the purest of materials must be employed. Distilled water should be used, but it must be obtained from a reliable source. That obtained from retail chemists or druggists is frequently very impure and useless for the purpose. A pretty sure test of its purity is to add a few grains of nitrate of silver to it, and if it shows no turbidity nor discoloration after a few hours'

exposure to sunlight it may be taken to be all right. If distilled water is unobtainable the best thing to do is to use ordinary tap water and purify it oneself. It is a very simple matter. Put the water, which should have been previously boiled and allowed to get cold, into a gallon white glass bottle and add a grain or two per ounce of nitrate of silver, and dissolved the water will be milky. Expose to sunlight for three days. The organic matter will combine with the silver and will be reduced by the action of the light, and can then be filtered out. Water so treated may be relied upon in making up all silver solutions, but not for other purposes, as it contains a small proportion of free nitrate of silver. If the collodion process is in continual use, and good distilled water is not to be obtained, it is a good plan to always keep a stock of water sunning for stock.

### How to Compound the Bath.

The nitrate of silver should also be of the purest, and known as recrystallised is what should be employed. Some of the old workers used to prefer the fused, as they considered it answered better than the crystallised in giving greater detail in the negatives, but the writer thinks that this idea is not founded—that is, if the crystallised is of good quality. The strength of the solution, it should be between thirty and thirty-five grains to the ounce of water. If it is less than that there will be a tendency to thin and unsatisfactory negatives, but no advantage whatever accrues from its being stronger than thirty-five to the ounce, with collodion iodised, according to the formula already given. A good formula for the sensitising bath is:—

Distilled or purified water	...	...	2½ pints.
Nitrate of silver	...	...	4 oz.

This will give us a bath of thirty-five grains to the ounce. It may here be mentioned that the solution gets slightly weaker by use, but it rarely falls below thirty grains. Therefore, better to make it this strength at the beginning.

When the silver is dissolved the solution requires to be iodised—that is, saturated with iodide of silver. Unless this is done, iodide of silver being soluble in a solution of nitrate of silver, the first few plates sensitised in the bath would have some of the iodide of silver dissolved out of the films. One of the objects of iodising the bath is to dissolve the silver in about a quarter of the full quantity of water and then add a solution of iodide of potassium until the iodide of silver, first formed, ceases to be dissolved. Then add the remainder of the water, when excess of the iodide will be precipitated, and can then be filtered out. This method ensures the complete saturation of the bath in a condition which is really not necessary. Another plan is to pour a little of the collodion into the bath and then well stir it. The method preferred by the writer is to iodise the solution after it is filtered by leaving a collodionised plate in the bath for some hours—say, all night. The solution then takes up as much iodide as it requires. It will be noticed, when this method is adopted, that the film, which after a few minutes immersion in the new bath was dense and creamy, becomes thin and transparent with the longer time owing to the solution having dissolved the iodide of silver. The solution must be filtered through either paper or a pledget of cotton wool plugged in the neck of a funnel. Personally, I prefer the latter, as

at is sold as filtering paper is by no means pure. The Swedish filter paper may be relied upon, but is rather expensive. To facilitate the percolation of the solution through the filter it is a good plan, after placing it in position, to wash it with a little alcohol through it, followed by a little distilled water.

The silver solution will then pass through quickly. The alcohol and the distilled water also remove any little impurities that may happen to be in the cotton-wool. After the solution has been filtered it should be tested for acidity with a drop of blue litmus paper, for with the iron developer the bath should be acid, but only slightly so. The less acid it is the better, so long as the bath works clear, for an excess has a tendency to slowness. If, at the end of a minute, the blue colour of the litmus paper has changed to a decided red, it may fairly be assumed that the bath is all right. It does not, however, follow that it is; that can only be determined by a trial plate.

### Adjusting the Bath.

When dealing with the compounding of the silver bath it was assumed that if, after testing it with blue litmus paper, it was found to be acid, it might be assumed that it is in the right condition. If, however, pure recrystallised nitrate of silver is used, the probability is that it would not show an acid reaction, or only a very slight one. Therefore, acid must be added—say, five or six drops of pure nitric acid to the quantity of solution given in the formula. A plate should now be tried in the dark-room. It should be coated with collodion and exposed in the bath till the film is freed from greasiness.

Without exposure to light, the iron developer is poured over the plate and allowed to remain on for a minute or two. The plate is then washed and fixed. If the film shows no trace of fog or streaking, and is as clear as the glass itself, the bath is in a satisfactory state for use.

It is here assumed that the reader has some little knowledge of the process. But the manipulation and the composition of the bath will be fully treated upon in future articles. I have, however, thought it well at this stage to deal at some length with the silver bath, as upon its state depends success with the process, particularly as after continued use it will become disordered, and will require to be rectified. Therefore, I shall deal with the whole of this portion of the subject at once. With this digression I will resume.

As just mentioned, the plate proves clear and transparent, and the bath is in a satisfactory condition. If, on the other hand, the plate should turn out fogged, it proves that either the nitrate of silver or the water was impure. Should, however, there be only a slight trace of fog, matters will generally be set right by the addition of a drop or two more of nitric acid to the solution. Should, however, the collodion employed in the testing be newly added, slight fogging may often be remedied by the addition of a small crystal of iodine, just sufficient to deepen its colour. It is better than adding more acid to the bath, if it is already decidedly acid, to test paper. If the fog is of a very decided character, no other treatment must be resorted to. It is here assumed that the collodion is above suspicion, and that may be assumed if any of the well-known commercial brands are employed. The treatment is then as follows:—The solution is put into a white bottle and a solution of carbonate of soda added until the carbonate of silver thrown down ceases to be dissolved, and the bath remains with just a milky appearance. The bottle is then exposed to the sun for a day or two. With this treatment the impurities which cause the fogging will be precipitated by the action of the light. The solution is then filtered and five or six drops of nitric acid added, when the bath should be found to work satisfactorily. If not, a drop or two more nitric acid should be added. Instead of treating the solution with carbonate of soda, freshly precipitated oxide of silver is theoretically better, but the carbonate answers all purposes, and is the substance employed by the most practical workers.

### Signs of Bath Exhaustion.

Sooner or later a bath which is in use will become disordered—there is no known way of avoiding it—and will require to be doctored. It will in time become supersaturated with iodide-nitrate of silver and over-charged with ether and alcohol from the collodion. The result of the former is the formation of pinholes, or sometimes of a sandy deposit in the negatives. It is a curious fact that a cold solution of nitrate of silver will hold more of the iodide-nitrate of silver in solution than will a warm one. It frequently happens, more especially in summer time, that a bath which in the early part of the day, while it is comparatively cool, will work quite satisfactorily, will later on, without any warning, yield only very pinholey negatives. If, under these circumstances, the plate be closely examined when taken out of the bath, fine crystals will be noticed sticking out of the film, and probably a plentiful crop of them will be seen at the bottom of the vessel. These are the iodo-nitrate of silver which have separated from the solution in the form of the fine needle-shaped crystals.

### Renewing an Old Bath.

The treatment in this case is to dilute the bath with about an equal bulk of distilled water, when the excess of iodide will be precipitated; for, as explained in the last article, iodide of silver is far less soluble in a weak solution of nitrate of silver than it is in a strong one. If the bath be now filtered the excess of iodide will be removed. After filtration the solution may be made up to its original strength by the addition of fresh nitrate of silver. Most workers, however, prefer to bring back the bath to its original strength by evaporation, and this is by far the better way, as then the accumulated ether and alcohol from the collodion—which is always more or less a nuisance—is got rid of at the same time. An excellent way of renovating an old bath (after it has been diluted and filtered to remove the excess of iodide) is to neutralise the acid with a little solution of carbonate of soda, and then put it into a large, clean, flat dish and expose it to sunlight until it is reduced to its original bulk. A glass plate should be put over the dish, raised an inch or two above it, to keep out dust and dirt. The bath is then filtered and acidified as before. Baths so treated, as a rule, work better than quite new ones.

Instead of evaporating the solution in this way some put it into a Berlin basin, over a Bunsen burner, and boil it down to its original quantity. This is a quicker way than the other, which is a somewhat lengthy one. But it is not better, if, indeed, so good, inasmuch as the organic matter is not so completely reduced as by the former method. Instead of merely evaporating the solution to its first strength, some go further, and drive off all the water and crystallise the silver, or even fuse it into a solid mass. An entirely new bath is then made up. In making up a new bath with such silver it is rarely necessary to iodise the solution, as it usually retains sufficient iodide in the crystals for the purpose.

When a bath is old, and has been much used, more especially in hot weather, it will found that after standing a few hours a thin scum is liable to form on the surface. This should be carefully removed with a strip of blotting-paper, and, if in the usual dipping bath, the solution should be well stirred up with the dipper; if in a flat tray, the tray should be well agitated. If a plate were put into the solution with a scum upon it the negative would show stains or markings on the surface of the film when developed.

By the methods just described, baths, however disordered they may be—of course, within reason—can be restored to good working order, but it will be realised that the operation takes time. Therefore, all careful workers keep a bath, known to be in good working condition, in reserve, so that when the one in use breaks down the other can be taken into use at once. The disordered one can then be dealt with at leisure.

E. W. FOXLEE.

# THE PHOTOGRAPHIC CONVENTION OF THE UNITED KINGDOM.

## TWENTY-SECOND MEETING.—IN HEREFORD.

THE proverbial good luck of the Convention in the matter of weather was in evidence when the proceedings opened on Monday at Hereford. The day opened with the sultry heat of the Sunday, but by midday an unobscured sky and a light refreshing breeze formed an altogether agreeable atmospheric condition, and up to the time of going to press no single item of the programmed fixtures had been affected by any cause. In municipal hospitality Hereford has shown itself a generous host. The Town Hall has been placed at the disposal of Conventioneers for headquarters, and the offices and large council hall in the handsome premises have provided all the accommodation which could be desired. The Hereford Photographic Society, its secretary (Mr. Cecil Gethen), and the hon. local secretary (Mr. W. T. Carless) may also be congratulated on their thorough-going support of the Convention, a support which has had its outward and visible sign in the record local membership of 120. This is eighteen more than the previous highest number of 102, reached in 1903, when the meeting was at Perth.

At 2.30 on Monday the members assembled in the council hall to be formally welcomed to Hereford by the Mayor (Mr. G. J. Caldwell), who in a few appropriate words expressed his pleasure at the selection of Hereford as the venue of the Convention, and referred to the valuable work of photographers in making and preserving records of beauty spots and objects of historic interest, such as Hereford and its surroundings contained.

Mr. E. J. Humphery (retiring president) then formally introduced Mr. Alfred Watkins to the meeting, and vacated the chair in his favour. In accordance with Convention custom, Mr. Humphery

was presented with a silver replica of the badge of office. Watkins then delivered his presidential address, and at its Mr. C. H. Bothamley, in proposing a vote of thanks, said he would like to add to the list of names of those who had advanced photography that of their new president. Mr. Watkins, he said, deserved all the credit that could be paid him for his work in giving quantitative character to the practice of photography and suggesting rules for guesswork. Mr. F. A. Bridge, in seconding vote of thanks, congratulated Mr. Watkins on his recovery from the effects of his recent accident.

On the proposition of Mr. Harold Baker, the thanks of the meeting were accorded to the Mayor of Hereford for his presence and words of welcome.

The meeting then composed itself to listen to the paper by Dr. Scheffer on "Microscopical Researches on the Grain in Gelatin Plates." Dr. Scheffer, who has recently joined the scientific staff of Carl Zeiss, and is known already to English readers by his contributions to the *BRITISH JOURNAL OF PHOTOGRAPHY*, proved to be an altogether charming lecturer. With needless apologies for an English enunciation which was only just sufficiently intelligible to be picturesque in places, he explained to his audience the nature of the scientific researches he has recently made into the structure of the silver image in developed gelatine plates. Dr. Scheffer's extraordinarily skilful section-cutting and photomicrography have given us an actual demonstration of the different kinds of grains which exist in the photographic plate, and explained the theory of the development of the latent image.

## PRESIDENTIAL ADDRESS.

THE first words addressed to the members on visiting a county which is new to them as a body must be words of greeting. It seems the custom for each county to take to itself the title of "the garden of England." I should rather regard England as a huge garden, and welcome you to Herefordshire, as one of its most fruitful and delightful corners, where the grass grows deep and lush, where the cottages peep out from the fragrant orchards as creations of native growth, where hill, vale, and wood combine in ever varying landscape; a county, too, watered by the most beautiful river in England, and dotted with more than its share of ancient churches and castles. Before the week is over I think that many of you will have touched the fringe of that curious individuality which distinguishes separate shires, and I trust that some of you will visit us again in the fruitful autumn time, when Herefordshire is at its best, more especially to the picture maker.

The year's work in the technics of photography has been one of steady and quiet advance. The invention of a distinct process, Ozobrome, by Mr. Manley, seems likely to be a most useful addition to available printing methods, as it produces carbon enlargements with the minimum of intermediate steps, and without any daylight exposure.

The revival of the oil or litho-ink process, by Mr. Rawlins, provides quite another kind of power to those who wish to convey a maximum of individuality to their photographic impressions, and promises to be the most elastic of printing methods for that end.

Orthochromatic and colour photography both make steady and satisfactory progress in the provision of more perfect dyes for the screens and for the silver halides; and methods of printing from the three-colour negatives are improving.

In the making of negatives, simple time development, as laid down and introduced by Hurter and Driffield, rapidly advances in favour. Its advance would be still more rapid had not its commercial advocates, in their efforts to produce an apparent simplicity, given a time for one stated temperature only. Several workers, however, who find it quite impracticable to develop at one even temperature, summer and winter, have, during the year, compiled and published

tables of times for different temperatures, which tables, of course, are only applicable to one developer and one brand of plate.

Whatever merit the factorial plan of development possesses in the fact that it allows for, and does not shirk, these variations of temperature, which, in the actual limits of practice, require variations of time to the extent of 300 per cent.

The tendency of the year in the matter of hand camera work has been in the direction of reflex cameras, and members have a good opportunity of judging their merit by the fine exhibition of such cameras shown here.

But the year's progress is not the subject I propose to dwell upon. The theme which I take is that of our national destiny in the matter of photography in the past and in the immediate future.

We are assembled as a national, as a British (using the word in its widest sense) Convention of Photographers, and I put it to you a glance at the causes which have given Britain a glorious record in the past is a distinct help to our position in the future.

There has been much misdirected inquiry on the question, "Who discovered—or invented—photography?" Almost as truthfully might be asked, "Who discovered Windsor Castle?" Our present practice of photography has been evolved—like all branches of science and industry—through the labours of countless workers, each adding at least one stone to the edifice of knowledge. Here and there stand out the name of a worker of surpassing genius or application, who has contributed a foundation, a story, or a whole wing to the building; and in giving due honour to such a name we are apt to forget how dependent he was on the work of others.

The present-day handicraft of photography (I do not treat of its artistic aspect) takes as an essential basis a negative image, formed out of sensitive silver halides and held on a transparent or translucent support. With it is required its complement—the positive print (in many forms) derived from it. What is the national aspect of the evolution of these two essentials? In tracing its history find British names so much in the majority, both as to minor workers and as to those who stand out as leaders in the march of progress, that photography might be truthfully described as

MEMBERS OF THE TWENTY-SECOND ANNUAL PHOTOGRAPHIC CONFERENCE

HELD AT HEREFORD.

Henry Greenwood & Co., Publishers,

THE  
JOHN C. CREED  
LIBRARY.

presented to the world—in the main part—by the steadfast genius of the British race. There must be some reason for this. It may be in some part the national temperament, but I think I find a fitting point in a name not usually associated with photography. The early pioneers of photography in Britain possessed in the work, the methods, in the achievements of the Cambridge professor, Newton, an impulse and an example which it is difficult to over-estimate. We all work with that implement which Talbot has happily called the Pencil of Nature. Newton found the knowledge of light a chaotic jumble. He left it so orderly and so comparatively simple that his book on "Optics," of 1675, might, with very little editing, serve as a first text-book for the modern student.

Let us briefly follow the line of evolution from this point, the era of the obscure Italian invention being already common knowledge. In 1770 Dollond, an English optician, invented means to achromatise lenses, and thus brought the optical side of the unborn art to comparative perfection before the chemical side had taken form. But at this time many observers, English and foreign, noted the blurring effect of light on silver salts. It was an English manufacturer, Tom Wedgwood, who, in 1802, made the first coherent and ordered attempts at true photography. He failed, chiefly for want of a fixing solution, but he tried to record the image of the camera obscura by photography, and if the solar microscope can be called a camera (as I think it can), he succeeded in producing the first camera image, although not a permanent one.

And then, in the next generation, came those great episodes, the making out of complete and successful photographic processes, almost simultaneously and quite independently, by Fox Talbot (a country gentleman with a science training), in England, and by Daguerre (a professional diorama painter) in France. Both inventors used sensitive silver salts, but, while Talbot followed in the steps of Wedgwood, Daguerre struck out in an independent line. Both inventors used perfect fixing methods, and both, a few months after publication of their processes, made them complete by the addition of hyposulphite of soda for dissolving the silver salts, as discovered by John Herschel, an Englishman of science.

While Daguerre's name will always shine as the genuine inventor who was probably the earliest complete process of photography, while it will always take a front position in the history of photography, I am bound to point out that his work takes a very minor position in the continuous evolution of the art. The Daguerreotype process died in the course of time; it left no family, no process derived from it. Talbot's process also died in course of time, but left a numerous family, for practically every succeeding process has been derived from it. Talbot had hit upon the essential point to make a negative from which prints might be taken. Daguerre only missed this essential, but it was impossible to attain it in his process. In the evolution of photography Daguerre's success was a great stimulus to the band of British workers, and he appears to have been the first to use iodide of silver as a sensitive salt. A complete negative and a complete print from it was first given to the world by Talbot, although he may be largely indebted to other workers completing his process. But they were all a British band of workers perfecting the same idea.

To use a simile borrowed from gold mining, Daguerre struck a pocket of ore, which was quickly exhausted. Talbot struck the main reef, thin at first, but rapidly widening out, and good for generations to come. Our present method of development is also directly descended from development with oak galls, published by Rev. J. B. Reade, in March, 1839, before the publication of Daguerre's method.

To follow down the chain of evolution: An English operator, Nicéphore Niépce, first used bromide of silver as a sensitive salt, adopting it in the Daguerreotype process, and thereby greatly increasing its stability.

Nicholas P. M. first used a glass plate as a support for the negative. Then a Frenchman, St. Victor, devised an advance on Talbot's process, in 1847, by using the silver salt with a film of albumen on a glass plate, and, although this process did not come much into use, it is an important link in the chain of evolution. Another Frenchman, Louis J. M. E. M., in the next year applied the suggestion to positive prints, and produced the albumenised paper, which soon superseded Talbot's plain paper prints.

Then Scott Archer, a British photographer, worked out the well-known wet collodion process in 1851. Collodion had been previously

suggested for the purpose, both by Bingham, in England, and Le Gray, in France, but neither produced a workable process. Wet collodion stood as the standard negative process for many years. The disadvantage of having to prepare the plate immediately before use caused a whole array of experimenters to attempt the preparation of a similar film to be used dry, and therefore capable of keeping. A Frenchman, Taupenot, made the first successful "dry plate," and innumerable English successes followed. And now came the idea to prepare the silver halide in its vehicle before coating the plate or paper. In other words, the era of emulsion photography set in, and at every stage of the march of progress the advance was made by one of the innumerable band of British workers.

Sayce and Bolton, Liverpool amateurs, produced, in 1864, the first collodion emulsion. Dr. Maddox, an English physician, following in the same lines, substituted gelatine for collodion, and British workers, such as Kennett, Burgess, and Bennett, chiefly amateurs, perfected the present gelatine plate, and incidentally secured to England the lead in a huge dry plate industry. After this period British supremacy probably wanes. Vogel, the German chemist, in 1873, introduced colour sensitiveness by staining the silver halides with dyes, and the German nation having captured the English dye industry by superior science organisation, they now have an overwhelming advantage for advancing in this work. In the same way, although the application of the earlier organic developers was entirely British (gallic acid, by Reade and Talbot, pyrogallol, by Scott Archer, and hydroquinone, by Abney), and alkaline development, a British invention (Russell), the manufacture of the developers has now passed to the German nation, who therefore have a natural advantage in devising new ones.

In direct printing processes Britain takes an overwhelming lead. Plain silver paper, the use of chromates for printing, blue prints, carbon, platinotype, collodio-chloride, and bromide emulsion paper are all British inventions.

In process work Niépce, in France, invented the bitumen process long before it could be usefully applied, and although Britain has contributed photogravure (Talbot) and Woodburytype, such processes as collotype, photo-lithography, and half-tone screen work have been worked out abroad. In three-colour work the genius of British investigators had pointed a clear path long before the time was ripe. Newton paved the way. Young discovered the physiological appreciation of light in three colours.

Clerk Maxwell, a Cambridge professor, in 1861, was the first to describe and demonstrate the outline of our present three-colour process, but the want of colour sensitive plates made it impossible to proceed further at that time. Vogel's discovery, previously referred to, made colour work possible, and the rapid advance since has been international, Ives, of Philadelphia, contributing largely.

Roll film photography was first devised in England, although made a commercial success and perfected by the use of celluloid in America. Conventioners will recall with satisfaction that absolutely the earliest cinematograph exhibition was made by the inventor, Friese Greene, at the Convention meeting at Chester in 1890.

In science researches bearing on the speed of plates and course of development, Britain can claim the leading place in the work of Hurter and Driffeld, although Germany, as regards the training and nationality of Dr. Hurter, bears a share of the credit.

In this brief and imperfect outline we have caught a glimpse of a long line of British workers—manufacturers, landowners, clergymen, physicians, traders, journalists, and professors—bound by a common desire for knowledge of the unknown, who have succeeded in presenting to the world a new power and a new art. Does not the vision carry a lesson to us, members of a British Convention, composed of the same elements, and bound by a common tie? Are there not still advances to be made, and can we not do our share in the work? Science is now cosmopolitan; we can cordially welcome any advance made outside our shores, but we should, in friendly rivalry, match each with one of our own. Is the body of earnest British investigators as large now as in the seventies? What can we do to enlarge it? Our council, by its grants to research, have shown that it is alive to the question, although, perhaps, the same sums might be quite as usefully spent by rewards to the best unpatented advances of the year. Individually, we can all do something. Even minor observations are of value if recorded, but they must be recorded in print or they perish. And this brings up the subject of our technical journals. It is said that a community gets just

the literature or journal it deserves, and this is probably true, although I find it hard to think that any community can deserve the knowledge-deadening contents of some of our morning newspapers. In photography Britain has been fortunate in its journals and their editors. On the title-page of the first volume of "The Photographic News" (1858) appears the name of William Crookes as editor, and it was a good commencement. But a journal can do no more than reflect the highest ability of the class in which it circulates, for no editor can make bricks without clay. There was a forcible example of this a few years ago in the photographic press of the United States, where, at the time, no considerable body of experimental workers existed, and editors had to fill their papers with clippings from English journals. But America is increasing her band of workers, and in some of the papers the proportion of British articles now only averages 50 per cent. Every conventionner can help in this matter by contributing to his journal, and not remaining a dumb subscriber.

Another way in which the health of the press can be upheld is to vigorously discourage the deadening introduction of the

trail of the advertiser into the editorial columns. In photography we are fairly free from this evil as yet, but there are alarming signs of its growth.

All of us, too, can aid in the national aim by supporting, by active work, our local photographic societies. They are the nurses of the minor workers, from whom the experimenters of to-morrow are recruited.

But it is by bringing our national, secondary, and science training somewhere near the standard adopted by our German cousins that our greatest hope lies. We are not standing still, but our methods are not so thorough as theirs, and, to follow the most advanced world photographic investigation, an ability to read German is now essential. And then, with British capacity tempered by German method, who can doubt that we shall still march on in the van of progress? For, in Milton's prophetic words, "Consider what nation it is whereof ye are: a nation not slow and dull, but of a quick, ingenious, and piercing spirit, acute to invent, subtle and sinewy to discourse, not beneath the reach of any point, the highest that human capacity can soar to."

### MICROSCOPICAL RESEARCHES ON THE GELATINE FILM.

THE subject of the researches, upon which I have the honour of addressing you, is, first, the morphology; and, secondly, the topography of the grain of photographic plates. As a rule, the greater public, especially the professional and amateur photographers, have

for the lecturer and for the auditors, a regrettable lack of success. It is possible to explain even the most difficult scientific question so that everybody with average knowledge can follow and understand everything. The path which I wish you to travel with me is that

certain misgivings as to such scientific lectures. Every science has a special language and special expressions, which have their special meanings. It is much to be regretted that sometimes the majority do not entirely understand such scientific lectures, which means, both

which I have traversed in my researches, and that which leads scientific research to a success.

There have been many researches published on the plate-grain. The subject of these investigations was either the grain of the

undeveloped plate or that of the finally, or nearly finally, developed plate. There has not been much published on the different stages of the formation of the developed grain. The first experiments which give me a clear question to be solved are shown by the photo-micrographs, Nos. 1-4.

A light-sensitive compound of silver was precipitated in water and developed. In Figure 1 you see bromide of silver, and in Figure 2 the result of the development of this salt. In Figure 3 you see another light-sensitive form of the silver compound, and in Figure 4 the result of the development. It can be clearly seen from

Fig. 8.—Germs visible after primary fixation. Magnification 2,000 times.

these figures that the developed grain is quite different from the undeveloped. It is neither similar to the original grain as regards the colour nor size. Also the chemical reactions of the developed grain are absolutely different from those of the undeveloped grain. Obviously Figures 2 and 4 are the final result of a process the different stages of which it was my first task to examine.

The first experiments were a failure, but still I think they are worth mentioning. The question was, What are the different stages of the formation of the developed grain? This process can only be examined

Fig. 9.—Developed with solution containing silver bromide.

under the microscope, and the experiments must be carried out in such a way that we develop less and less until finally we see the first just visible commencement of the development. It is not possible to carry out these experiments with bromide of silver precipitated in water. In this case the usual form of the emulsion in gelatine is of great help. Plates were very thinly coated with emulsion. The gelatine has the very convenient property of retarding chemical processes, but itself does not take part in the said processes. In the next series of experiments a number of thinly coated plates were exposed for the same time, and developed for different times, so that at the first visible stages of development could be detected.

In Figure 5 you see undeveloped bromide of silver enlarged 2,000 times. In Figure 6 you see the very first stages of development. Around the original grains you see fine bodies.

They are formed by small knobs, which are connected with the original grain by fine straight or curved filaments. Sometimes in the path of such a filament can be seen two or three of these knobs, sometimes the knobs are quite close to the original grain without any filament; sometimes a fairly thick filament is visible which does not show a knob.

These small formations, which are the first stages of development, are very probably due to something like an eruption, which is caused by the action of light upon the bromide of silver. Small particles are shot off, and they pierce the gelatine, thus forming these filaments. Sometimes their path through the gelatine is straight, sometimes curved; it may be long or short. Sometimes a piece of the shot-off particle is arrested on the way, and another one penetrates further. Sometimes the particle which is shot off reaches nearly intact the end of its path, and sometimes it is exhausted on the way through the gelatine. In this case we have a relatively thick filament without a knob. These processes can be made visible with every developer and every emulsion of bromide of silver.

Fig. 10.—The result of short exposure.

The micro-photographs shown here are made with an apochromat of 2 millimetres focus and N.A. 1.40, constructed by the well-known firm of Carl Zeiss, of Jena. It is possible to make these germs visible in quite another way, and we can show that really they represent the latent image. It is well known that it is possible primarily to fix out exposed plates and afterwards, to develop them with solutions containing silver. Figure 8 shows the result of such an experiment. The original grains are dissolved by the hypo the germs have resisted. If we develop somewhat longer we have forms like Figure 7. Around the germs a large black grain is formed on development. You can see very well that this developed grain is situated outside the original grain. The longer we develop the more this developed grain grows, and finally it covers the original grain entirely.

That the original grain originally remains in its original form inside the developed grain can be easily shown. If we dissolve the original grain with persulphate of ammonia we see the little bodies remaining, as described by Dr. L  ppo-Cramer, and the original grain.

The next question is, What forms the developed grain?

I can only partly answer that question. But what I am going to state here adds considerably to our understanding of those processes which are important in negative making. Figure 9 shows you the development in a somewhat modified form. If we examine very carefully normally exposed and shortly developed emulsions under the microscope we see that all the grains do not show the germs here described. Those grains, around which we do not see germs, become very faint after some developing, and the developer seems to have dissolved them. If we develop longer these germless grains finally disappear. Figure 9 shows you this fact. In the exposed plate we

have two sorts of grains. First, original grains—i.e., grains which have around them the aforesaid germs; and, secondly, what I should like to call nourishing grains, which do not show any germs. These grains are dissolved by the developer, and form the developed black grain around the germs. The original grains are not touched by the developer. Figure 9 was obtained by dissolving some unexposed

we see the result of solarisation. The emulsion, Fig. 12, exposed 60,000 times as long as the first one. This solarised emulsion gives a result very similar to the very shortly exposed one. We see developed grains and also very many undissolved nourishing grains. From these figures it can be seen that to give a maximum exposure means to induce the condition in which the relative number

Fig. 11.—Exposure 100 times that for fig. 10.

Fig. 12.—Solarised image—exposure 60,000 times that for No. 10.

Fig. 13.—The effect of a weak developer.

Fig. 14.—The result of a strong developer.

bromide of silver in the developer. The consequence was that the nourishing grains were less rapidly dissolved, and they remained visible in the plate developed rather long.

In the next series the influence of the exposure was examined, all other conditions remaining unchanged. Figure 10 shows an emulsion exposed for a very short time. We see the developed grains and a large quantity of nourishing grains yet undissolved. In Figure 11 all the nourishing grains have disappeared. In this case, Figure 11, the exposure was a hundred times as long as the first. In Figure 12

nourishing and original grains is favourable to the formation of maximum masses of developed grain.

Apparently, there have not been enough germs formed in the unexposed plate, and the over-exposure has brought too many grains into the state of original grains, so that we have here a lack of nourishing grains. In my former articles in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, I have used the expression "dissolving grain" instead of "nourishing grain." I am very much indebted to Dr. Siedentopf, of Jena, for this very characteristic and significant expression.

In the series of experiments just described we only changed one condition, the energy of light which acted upon the plate. In the next series we do not change anything but the concentration of the developer. In Figure 13 you see a plate developed in a very weak solution, and in Figure 14 developed in a stronger solution. All other conditions were absolutely unchanged. You observe that in Figure 13 the weaker developer has not been able to dissolve all the nourishing grains, and has produced the maximum of development—i.e., maximum developed masses.

Now we come to the second part of our subject, and we shall examine the topographic distribution of the plate-grain in the film. These sections are made with a microtome. First, the film has been

exposed part the majority of the developed grains lie quite in the upper part of the film, and in the longer-exposed part we find the developed grains also in the deeper parts of the film.

This fact will be very useful and of great assistance in enabling us to understand the different processes of intensification and reduction. It is well known that not every plate that is developed is suitable for printing, and very often an after-treatment—i.e., intensification or reduction—must be resorted to. I will restrict myself to the examination of only three or four typical processes. The morphological changes in the intensification are shown by Figs. 19 and 20. In these experiments the same part of the plate was photo-micrographed before and after intensifying with chloride of mercury and ammonia. You see that all grains visible in Fig. 19 are enlarged, and

Fig. 15.—Early development.

Sections through films which have received different exposures.

fully stripped off, and after different treatments it has been made ready for cutting. It gives me the greatest pleasure to have the opportunity of thanking my friend, Herr W. Loew, care of Herr G. of Heidelberg, for the excellent microtome which he has put at my disposal. It has afforded me considerable assistance, and it is a pleasure to work with an instrument of such high precision. It has been easy for me to make with it sections of 1/1000th of a millimetre. We expose two films for the same time and develop them for different times we have results as shown in Figs. 15 and 16. Fig. 15 shows a slight development, and Fig. 16 the final result of prolonged development. The films are then fixed with hypo. A comparison of the two figures shows us that the developed grain grows in the course of development, as we have already seen. We see, however, that the developer diffuses gradually into the depths of the film.

Figures 17 and 18 show the influence of the intensity of the action of light, all other conditions unchanged. We see that in the shorter-

thicker in Fig. 20. It seems at first sight that in Fig. 20 some new grains are formed, but this is not the fact. If you observe more carefully you will see that those grains which seem to be newly formed can be seen in Fig. 19 as faint shadows. They did not extend into the focal plane of the microscope, and therefore, and through their small size, only gave traces of shadow-like images. As the result of intensification they became larger and the conditions for visibility improved. From these figures we can see that the intensification is nothing more nor less than an enlargement of those grains which already exist. Intensification never forms new grains, only the mass of the already existing grains becomes enlarged. It is quite easy to understand the importance of this fact as regards the increase of the contrasts in the image. Every single grain becomes enlarged.

The opacity of parts which are richer in grain must be increased much more by the intensification than the opacity of parts which have been less exposed, and therefore are poorer in grain.

From this it can be easily understood that every intensification must raise the contrasts in the negative.

We will first study reduction with ferricyanide and persulphate of ammonia. It is well known that these two reducers act very differently. Farmer's reducer increases the contrasts and the persulphate diminishes them. Every reduction is a more or less complete solution of developed grains. The difference between the action of the ferricyanide and the persulphate of ammonia reducers was clearly shown in the illustrations to my previous paper ("B.J.," Dec. 7, 1906, p. 964). The ferricyanide reducer has only penetrated to a certain depth. But in those parts where it has penetrated it has dissolved all grains. The persulphate of ammonia, on the other hand, has penetrated into the deepest parts, right up to the glass, and has diminished all grains equally. Before reducing, both parts had the appearance of the lower untouched part of the ferricyanide section, where the

Fig. 19.—Before mercurial intensification.

Fig. 20.—After mercurial intensification.

grains are absolutely untouched. We have already seen that in shortly exposed parts of the negative the grains are distributed near the surface, and the more the plate is exposed the more the mass of the developed grains extends into the depths of the film. In a certain way of speaking the developed grains are arranged like a flight of steps. If we dissolve, as happens in the case of Farmer's reducer, only the top layers of the developed grains, it is obvious that in the less exposed parts we can dissolve the whole mass of developed grains; whilst in the more exposed parts in the depth of the film, a considerable mass of developed grains may remain untouched. The action of the persulphate of ammonia is quite different. It attacks all grains evenly, no matter whether they lie in the top parts or down in the depths of the film, and therefore the latter reducer must render the parts rich in grain relatively less opaque than those poorer in grain, because, in the first named parts, a much greater loss of mass takes place. Lately Dr. Lüppo-Cramer has found that if we add sulphocyanide of ammonia or a similarly acting substance to the persulphate of ammonia, this works exactly like Farmer's reducer.

Fig. 21 shows clearly that in this case the persulphate of ammonia behaves topographically exactly like Farmer's. From this it is clearly seen that the kind of action of the reducer—i.e., whether it works harsh or softly, depends upon the relation of the velocity of the diffusion and the time in which it dissolves the grains. We have another means to diminish the contrasts of negatives at will to reduce it at the same time. This process was published by Obernetter, and recently Herr Hans Werkner has improved the formula. We can bleach out the developed negative, for instance, with hydrochloric acid and potassium bichromate. The neg-

Fig. 21.—The effect of persulphate plus sulphocyanide.

can then be easily re-developed. We can allow the developer to penetrate into the depth as far as we like. We have also seen several times that in the more exposed parts the grains extend deeper into the film. We can allow the re-developing solution to diffuse into the depth as much as we please; that means that we can completely re-develop the less-exposed parts, whilst a considerable portion of the deeper layers of the more-exposed film remains undeveloped. We can observe this fact very well if we examine a negative through the glass. At the right moment we can stop development and dissolve the bleached grains not yet developed. By this we can considerably diminish the opacity of the exposed parts, without having reduced the less-exposed parts. This process is, to a certain extent, even superior to the reduction with persulphate, because it does not in the least reduce the shadows. On the contrary, it increases slightly the opacity of the under-exposed parts, whilst with persulphate of ammonia we cannot avoid reducing the shadows.

DR. W. SCHEFFER

### THE CONVERSAZIONE AND EXHIBITION.

ON Monday evening a large company filled the halls and corridors of the municipal building, where they were received by the Mayor and by Mr. and Mrs. Watkins. Among those present, in addition to the retiring president and Mrs. Humphery, were G. W. Atkins and Mrs. Atkins (Elstree), Harold Baker (Birmingham), J. H. Baldock (Croydon), F. A. Bridge (London), George E. Brown (London), George J. Caldwell (Mayor of Hereford), Fred B. Catley (Harrogate), C. M. Channon (Cheltenham), Thomas Clarke (Moseley), Henry J. Comley and Mrs. Comley (Stroud), A. H. De'Ath and Mrs. De'Ath (Ashford), Ernest B. Docker (Sydney, N.S.W.), W. E. Dunmore (Purley), Gus Edwards (Hereford), S. Herbert Fry (London), Cecil Gethen (Hereford), Miss H. Rosalind Goodey (Derby), W. A. Grosvenor (Hereford), A. Horsley Hinton (London), Cuthbert Harrison (Sligo), T. A. Knoblauch (Edinburgh), C. Phipps Lucas and Mrs. Lucas (London), Walter Potter and Mrs. Potter (London), Alfred Roods (Croydon), Misses M. E. and F. A. Roods (Hastings), Dr. W. Scheffer (Berlin), Thomas Scotton (Derby), W. H. Smith

(Purley), Frank C. Starnes (Dartford), W. Tate (Keighley), Turnbull (Blackhall, Midlothian), Herbert J. Unwin and Mrs. Unwin (Hereford), H. Snowden Ward and Mrs. Ward (London), A. Watkins (Hereford), Joseph Watson (London), F. Welch (Lea), Courtenay Wells (Gloucester), Edward Woodward and Mrs. Woodward (Macclesfield), William Andrews (Hull), Alfred Atkinson and Mrs. Atkinson (Leeds), Harold Baker (Birmingham), Arthur C. Baldwin and Mrs. Baldwin (London), C. S. Bay (Birmingham), R. R. Beard and Mrs. Beard (London), George Bingley (Leeds), C. H. Bothamley (Weston-super-Mare), John Brand (Leeds), and Miss Brand (Perth), T. M. Dickinson (London), P. L. Earl (Leeds), Mrs. Earle (Hafod), E. Bartley Finn (Hendon), C. E. M. F. (Ventnor), Henry C. Jones (Rhayader), S. G. Kimber (Southampton), Colonel J. D. Lysaght (Chester), A. S. Ray (London), A. Seaman (Sheffield), J. B. Simpkins (Chichester), Thomas Taylor and Mrs. Taylor (Birmingham), James Taylor and Mrs. Taylor (Leeds), P. J. Thomsen (Brussels), J. W. Wade (London)

so. W. Watson (London), Alfred Ellis (London), W. Willis (London), W. S. Hobson (Leicester), F. J. Mortimer (London), and Ibbetson (London).

The exhibits included a very tasteful display by the Platinotype Company, who showed some excellent examples of platinotypes worked up in water-colours, as well as examples of Japine and other brands of platinotype paper. The reflex cameras and prints recently won at the "B.J." house attracted much attention, as did also her apparatus at the stall of Kemp and Brook.

At the annual general meeting, held on Tuesday evening, Mr. J. Humphery proposed, and Mr. F. A. Bridge seconded, that an invitation for the 1908 meeting from Brussels be accepted. An amendment, proposed by C. H. Bothamley and seconded by A. Horsley Hinton, that the 1908 meeting be held in the United Kingdom was lost, and the original motion was carried.

On Wednesday the official group was taken by Mr. Herbert J. Edwin, of 42, Commercial Road, Hereford, by whose kindness and comititude and that of the London Studio, who delivered the finished block within six hours of the receipt of the print, we are enabled to present it with this issue. The key to the group will be given next week.

At the council meeting, held after the annual general meeting, Sir Cecil Hertslet, Consul-General at Antwerp, was elected president 1908.

Votes of condolence with the families of the late A. L. Henderson and John Stuart, of Glasgow, were passed.

The exhibition of photographs in natural colours by Mr. H. J. Smiley, of Stroud, exhibited in the Town Hall, has attracted considerable notice and favourable comment.

## Photo-Mechanical Notes.

### Brass as a Substitute for Copper Half-Tones.

Now that copper seems to be getting higher and higher in price attention must be given to finding a substitute for it in half-tone making, says the "Inland Printer." Zinc is such a substitute, and much of the engraving that uses up valuable copper could be done on it just as well. We have in brass a perfect substitute, if manufacturers of brass would make a special alloy for the use of engravers and maintain the alloy of zinc and copper in its composition at exactly the same proportion. The trouble with the brass found in the market is that the alloys vary even in the same sheet so that it etches unevenly. Tin and other metals and impurities are allowed to get in. If the copper and zinc were properly selected before smelting and care taken in the manufacture, particularly in the rolling, brass half-tones would be more common than those of copper. Brass was used many years ago, and has been occasionally used.

**ETCHING PROCESS.**—No. 18,217, 1906. The object of the present invention is a photographic etching process in order for furnishing a face that admits of etching with a drawing, or the like, in which it is necessary to cover those places which are not to be affected by acid with a substance capable of resisting the acid. This coating the surface to be etched may be done by hand or by a photographic process. By the latter means the transfer, development and etching of drawings which consist of points or strokes, is possible. The drawing thus produced, however, only represents one tone. A picture developed by photographic means in asphalt, gives an exact copy of the original in this material in all depths of tone, could not be made as the thin parts of the coating corresponding to the lightest of the picture, offer the same resistance to the acid as the thicker parts of the coating. Assuming that etching can only take place at those parts which are not covered, then the coating prevents the etching is gradually removed in accordance with the photographic tones, or, in other words, the surface is made more and more accessible to the acid. It follows that by this means an etched gradation from light to dark would be the result. In accordance with this invention, the surface to be furnished with the picture is coated with a substance sensitive to light, such as asphalt, which, when the copied picture is being developed, either permits the coating to be correspondingly dissolved to the toning, or allows the acid to

penetrate freely, whereupon the picture to be produced is copied for instance by means of a negative. When the surface to be furnished with the picture is coated with asphalt, which is the sensitive coating, then the process is as follows:—A developing medium, turpentine, is poured over the copied plate, which is then placed in the acid bath. To the latter is added a dissolving medium which dissolves the varnish freed by the beginning development. Alcohol or any other suitable preparation for dissolving the coating would serve the purpose. Now the following takes place. The turpentine having penetrated the coating develops the copied picture. The dissolving medium added to the bath has meanwhile dealt with the coating medium—in this case varnish—removed by the developer, and the acid works by following the hole to a depth corresponding to the degree of the tone of the picture, i.e., the etching parts are etched to a depth in exact proportion to the removal of the different parts of the coating. After the etching process has taken place, the surface represents a relief, the depths and tones of which correspond exactly to those of the picture. Anton Dillmann, 6, Herrngartenstrasse, Wiesbaden, Germany.

### PHOTO-MECHANICAL PATENTS.

The following Patents have been applied for:—

**PRINTING.**—No. 13,573. Improvements in means for use in photo-mechanical printing processes. Franz Spaeth and Richard Charles Scrimgeour Austin, 321, High Holborn, London.

**PROCESS PLATES.**—No. 15,214. Machine for spreading an even-surfaced film upon copper, zinc, or other photo process plates. Clive Burton Heaton and William Alfred Catherwood, 7, Pocock Street, Blackfriars Road, London.

**INTAGLIO.**—No. 11, 849. Photo-mechanical intaglio for transferring ceramic inks on china. Thomas William Lascelles, Maybury Studios, Maybury Gardens, High Road, Willesden Green, London.

## Patent News.

The following applications for patents were made between July 1 and July 6:—

**REFLEX CAMERAS.**—No. 15,199. Improvements in reflex or reflecting cameras. John Edward Thornton, 6, Bank Street, Manchester.

**COLOURING PHOTOGRAPHS.**—No. 15,249. Improvements in the application of colour to photographic pictures and the like. William James Townsend Barker, 56, Ludgate Hill, London.

**STORAGE CASES.**—No. 15,277. Improvements in receptacles for photographic papers and the like. Charles Coventry and Henry Williams, 15, Carrington Road, Liscard, Cheshire.

**CINEMATOGRAPHS.**—No. 15,333. Improvements relating to duplex or multiplex cinematograph apparatus and the like. Robert Thorn Haines, 322, High Holborn, London.

**MINIATURE CINEMATOGRAPH.**—No. 15,449. Miniature or toy cinematograph. Oskar Messter, 4, South Street, Finsbury, London.

**CINEMATOGRAPHS.**—No. 15,459. Improvements in moving picture projecting machines. Siegmund Lubin, 322, High Holborn, London.

**FRAMES.**—No. 15,560. Improved back and method of adjustment thereof to photo frames. Charles Westwood, Gold Street, Pendleton, Manchester.

### COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

**MAGAZINE CAMERAS.**—No. 16,148, 1906. This invention relates to magazine photographic cameras, and has mainly for its object to provide improved mechanism for moving the sensitised plates of films into and out of position for exposure in cameras which are used with focussing screens, whereby objects to be photographed can be focussed in the usual manner at the back of the cameras. The magazine is arranged at the top of the camera (but it may be arranged at the sides or bottom) and is provided

with a slide for withdrawing the sensitised plates or films one by one from the said magazine and returning them thereto after exposure, the focussing screen being arranged so that each plate or film as it is moved into the camera moves the said screen out of its normal or focussing position and takes its place.

A convenient arrangement for carrying out the invention is as follows:—The slide for moving the plates or films from the magazine into the camera, and hereinafter termed the plate-slide, is in the form of a rectangular frame into which the front one of a series of such plates or films, carried in suitable carriers, is pressed by a spring piston or plate, the said front plate or film being prevented from passing through the frame by guide strips on the sides of the magazine. These guide strips are pointed or tapered at their lower ends so that as the plate-slide is moved upwards after exposing the plate or film carried thereby, the said plate or film will be guided to the front of such strips into the front of the magazine, the front unexposed

plate or film being pressed into the said plate-slide when it again reaches its upper position ready to be carried down into the camera for the next exposure. The exposed plates or films are maintained in an upright position by a spring piston or plate. Convenient means for operating the plate-slide comprise rack-teeth on the sides thereof engaged by pinions on a shaft operated by gearing from a handle outside the camera. The focussing screen is carried in a frame pressed forward into its normal or focussing position by suitable springs and provided at its upper end with an incline against which the lower ends of the plate-slide (which is preferably inclined also) impinges when the latter is lowered, so that the said screen is moved out of position, the plate or film in the plate-slide taking its place. To avoid the use of a focussing-cloth a bellows extension, preferably spring actuated, is employed at the rear of the camera, and provided with an opening for the eye of the operator, which opening can be closed by a shutter while a plate or film is being exposed. To prevent light penetrating into the magazine when focussing, a sliding shutter is employed to cover the slit through which the plate-slide works, the said shutter being normally pressed forward by a spring or springs and operated to uncover the slit, when the plate-slide is moved down, by one or more pivoted arms engaging cam surfaces on the said plate-slide.

The figure is a sectional side view of a magazine photographic camera constructed in accordance with the invention, the parts being in the position they occupy when the camera is not in use. Walter James Gilchrist and Johns, Son, and Watts, Limited, 40, City Road, London.

**REPEATING BACK.**—No. 18,690, 1906. This invention relates to photographic cameras and has particular reference to those in which a series of photographs can be taken upon one sensitive plate. A screen is provided having a movable opening which can be arranged to allow the image to fall in succession upon various parts of the plate held in a dark slide movable relatively to a stationary camera-back. This movement of the dark slide is in one path only, that is to say, if it moves horizontally relatively to the back, it cannot or need not move vertically, and vice versa. The screen may be in the form of a plate or panel fitting in the camera at the place usually occupied by the sighting screen, the openings in the screen being then so arranged as to control the vertical position of the pictures on the plate, whilst the horizontal position is determined by sliding the dark slide into definite predetermined positions relatively to the camera-back.

The screen itself comprises two members relatively movable to give the openings in the required positions. For instance the front member may be furnished with a slot having its width equal to that of the required small photograph, and its height equal to the vertical distance from top to bottom of the plate.

Fig. 1.

Fig. 2.

Moving behind this front member is a slide or shutter having two or more openings so arranged that they can be brought into register with the slot in the front member and in conjunction therewith give the necessary space for one of the small photographs, all the rest of the slot being cut off by the shutter. A sliding bolt or catch may be provided to keep the two parts of the screen in any required position.

Instead of the shutter sliding longitudinally behind the front member of the screen, it may be arranged to rotate in a recess

Fig. 3.

Fig. 4.

in which case it is convenient to provide the required number of openings in the front section and say one opening in the revolving shutter, a catch being also provided in this construction to keep the parts in register. This revolving pattern screen may be made so as to fit into a recess in the back of the camera in front of the dark slide. By the use of the screen in conjunction with a movable dark slide any required number of photographs can be taken upon one plate, the screen controlling the number of rows vertically upon the plate, and the movement of the dark slide the number of photographs in each row, all the changes being accomplished without any reversal of the dark slide or of a mask used in conjunction therewith.

The invention may be applied to cameras without any alteration of the structure of the body portion, the screen being fitted to the back, or, as before mentioned, in the place provided for the sighting screen. Figure 1 is an elevation of one form of screen according to this invention; figure 2 is a similar view with one member of the screen removed; figure 3 is an elevation showing a slightly different form of screen, also according to this invention in place in the back of a camera; figure 4 is an elevation corresponding to figure 3, but viewed from the opposite side. Reginald Herbert Payne, 43, High Street, Aylesbury, Buckinghamshire.

**DAYLIGHT FILM PACKS.**—No. 12,003, 1906. This invention relates to detail improvements in daylight loading packets of flat photographic films of the type in which a spring division plate is employed to hold the films up to focus, and in which the films are provided with extensions terminating in film manipulating tabs which pass through light-tight valves in the packet. Reference may also be made to former patents Nos. 4,995 of 1904
